SUPPLEMENT TO "THE ELECTRICAL ENGINEER," DEC. 29, 1893.

THE

ELECTRICAL ENGINEER.

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

VOLUME XII. (NEW SERIES.)

FROM JULY 7, 1893, TO DECEMBER 29, 1893.

LONDON:
Printed and Published for the Proprietor by BIGGS & Co., at "THE ELECTRICAL ENGINEER" Offices, 139-140, Salisbury-court, Fleet-street, E.C.

1893

INDEX TO VOL. XII. (New Series.)

NOTE.—General Articles, Correspondence, and Companies' Meetings are indicated by heavier type (thus, **290**) than the Notes and Business Notes, references to which are shown by light type (thus, 290).

THE

ELECTRICAL ENGINEER.

No. 1, Vol. XII. LONDON, JULY 7, 1893. PRICE 3D.

NOTES.

Salzburg.—On Sunday, 30th ult., the electric railway up the Mönchsberg, in Salzburg, began running from seven in the morning to eleven at night.

French Accumulators.—The series of lawsuits brought by the Société Française d'Accumulateurs Electriques is ended. All the makers of accumulators have had judgment pronounced against them.

Ashton Technical School.—On Saturday the Heginbottom Technical School was opened at Ashton-under-Lyne. The school has been built with a bequest from the late Mr. George Heginbottom of £10,000, with an additional £3,000 from the Corporation. The new school is well equipped for science teaching.

Telephone to the Summit of Snowdon.—Sir Edward Watkin, Bart., M.P., is now in course of fixing a telephonic wire between the summit of Snowdon and the post office at the Vale of Gwynant, on the picturesque slope of which his beautiful châlet stands. The service was opened yesterday, in celebration of the Royal wedding.

South London Electric Railway.—Some readers may have noticed, without enquiring into details, a reference to an accident upon this line. The accident had nothing at all to do with the electric working, but was a mishap to one of the lifts, caused by a rope breaking. The passengers in the lift at the time, though much shaken, were not injured.

Royal Institution. — The special thanks of the members of the Royal Institution have been returned for the following donations to the fund for the promotion of experimental research at low temperatures: Ludwig Mond, Esq., £500; Robert Hannah, Esq., £50; Sir Walter Gilbey, Bart., £21; Henry Arthur Blyth, Esq., £21; James Blyth, Esq., £21.

Financial Results of Walsall Tramways.—At the annual meeting of the Tramways Institute last week, Mr. A. Dickenson, of the South Staffordshire Tramways, said that he hoped at the next meeting to give the results of the working of the Walsall electric tramways, and which he believed would convince anyone that the overhead trolley system was the best method commercially.

Testing Institute.—An electrical testing establishment, the first of its kind in Scandinavia, has been opened in Stockholm by Herr Axel Estelle, a well-known Swedish electrical engineer. The establishment, modelled on the Physikalischtechnische Reichsanstalt, in Berlin, undertakes the testing of electric apparatus by instruments supplied by the institution named, the drafting of plans for electrical installations and estimates, and so forth.

Station Testing.—M. Desruelles (36, Rue de la Boetre, Paris) have recently produced a testing set of considerable convenience and small size. The set contains an astatic galvanometer (Nobili) of great delicacy, a Wheatstone bridge, a box of resistances (12 coils), a double-contact key, terminals, and a battery of eight cells of Street and Desruelles's pattern, hermetically closed. A drawer is added for pen, ink, paper, and note-book.

Coast Communication.—Telegraphic communication has been established with Lundy Island. This is one of the important firstfruits of the report of the Committee on Coast Communication. The island forms a natural refuge in rough weather, and it has been no uncommon thing for a score or two of vessels to lie storm-bound in the lee of Lundy, while for days the gravest anxiety prevailed in regard to them in the Bristol Channel ports.

Water Connection.—From Havana a curious accident is related, occurring to the lighting cable crossing the San Juan river at Matanzas. A long span was used, and one night one wire burnt off, and both ends fell into the water. Flashing was noticed, but in the station and the city no change was observed in the lighting, so it was left till the morning, when the wires were spliced. The lighting current had gone through the water all night.

Krebs Telephone Transmitter. — Commandant Krebs, major of the Sapeur-Pompiers (Fire Brigade) of Paris, has devised a convenient magnetic telephone transmitter, by which notice of fire can be transmitted instantaneously to the brigades and police stations. The transmitters are placed under the fire alarm posts, and can be spoken through when the glass is broken. The officers carry a portable transmitter for testing the alarms.

Electric Launch at Bath.—An electric launch, owned by Mr. Ernest Pitman, took a party of local newspaper representatives a trip from Bath to Saltford last week, under the direction of Mr. Metzger, engineer and manager of the Bath electric light works. The launch is provided with accumulators to run 35 miles at five miles an hour. The "White Swan," as the launch is called, took the party a very enjoyable run in spite of rough wind. Mr. Pitman's boat has room for 10 persons, and the Bath Electric Lighting Company are willing to supply pleasure-boats, recharging them when occasion requires.

New Theory of Electrostatics.—M. Vaschy (Académie des Sciences, June 5) proposes to show that the theory of electrostatics can be established on simple experiment and reasoning, leaving aside the hypotheses which, in present theory, seem indispensable—viz. (1) actual existence of electric masses acting on similar masses and even, according to certain physicists, on ponderable matter; (2) extension of Coulomb's law $\left(f = \frac{m\,m'}{r^2}\right)$ on reciprocal actions of these masses; (3) the hypothesis of induced electrification in dielectrics.

Canal Trolley Traction.—The scheme for running canal boats by overhead electric trolley traction seems to be taken up with some promise of success in America. Governor Flower has undertaken to champion the cause of the trolley canal boat. He has suggested an appropriation

for the purpose from Congress, and the superintendent of canals, Mr. Hannan, is prepared to receive plans and suggestions. The problem is to supply power in small units (25 h.p. to 100 h.p.) along a line 300 miles in length. Governor Flower thinks the whole cost would not be over a million dollars (£200,000) to fit 12 power-houses 30 miles apart, and the cost 2s. 6d. per day per boat. It is thought by electrical engineers that this estimate is too low in both cases, but that the project is worthy of attention.

Electro-Hygiene. — Mr. Newman Lawrence's new venture, *Electro-Hygiene*, the electro-medical paper, has, it appears, achieved quite a success, for the first edition went into a second edition. Amongst medical men, nurses, and those interested in the application of electricity to medicine it will certainly do good. A forcibly-written criticism on the backwardness of the medical journals in general, and the *British Medical Journal* in particular, in dealing with electropathic belt and similar quackeries, is given in the second number. While they hung back the *Electrical Review* stepped in, and "as it is now, the medical profession and the public have to thank the electrical journals, and not the medical, for the instructive lesson on electropathic belts given by the recent proceedings in the law courts."

Marriage-Day Illumination. — The Edison and Swan Company will display at their head office, Victoria-street, an immense radiating star, bulging to a central circle, enclosing the letters "V.R." and "G. M." The star is of 50ft. circumference, and built up of a thousand 8-c.p. incandescent electric lamps of various colours. The current is supplied from Deptford by the London Electric Company by special leading wires from their mains. The *Illustrated London News* has arranged with Captain Ronald Scott for a searchlight projector, with which portraits of Prince George and Princess May will be projected on the clouds to the delectation of the populace. Other large electric illuminations are to be seen along the line of the procession, considerable advantage having been taken of the electric companies' mains.

Electric Interference in a Liquid Layer.—To produce electric interference, M. R. Colson (*Comptes Rendus*) uses a Ruhmkorff coil fed by a thermopile. The ends of the two copper wires from the coil are in contact with a moderately conducting layer, formed by a liquid cooling on a glass plate. The two contacts form two poles, whence the electric flux is propagated in the liquid coating in periodic circular waves. A telephone is used with a contact movable in the liquid layer, the other contact being insulated and in connection with a constant capacity. In this manner the neutral point can be examined, as in wires, as the perception of the minimum sound is perfectly distinguishable. A series of points is thus obtained giving a neutral continuous line whose form varies according to the nature of the liquid, the distance separating the two poles, and the strength of the current passing.

Electric Time.—One of the most convenient methods of distributing the correct time is evidently by way of electric control. Moreover, the control itself may be made to work the movement of the clock hands with very little mechanism save an electromagnet. Such a system is in use in the General Post Office. The system is carried out to a considerable extent in New York by the Time Detector Company, 234, Broadway. Mr. J. S. Morse has perfected both a self-winding regulator electric clock and the secondary dials (illustrated in *Scientific American* for 17th inst.). The regulator has a full-length pendulum beating seconds wound by electricity—that is, self-winding. The circuits are connected so that every dial can be set by a key in the regulator. A gauge is also in circuit, showing the state of the battery, so adjusted that a bell rings when the battery weakens. Hundreds of dials have been in use for years, it is said, without once giving inaccurate time.

Train-Lighting.—The De Meritens primary battery was recently tried for a few months on the French Chemin de Fer de l'Est and de l'Ouest simultaneously. The elements of this cell comprise a plate of zinc between two platinised lead plates, the latter pierced with holes to facilitate the disengagement of the hydrogen. The liquid is one part sulphuric acid to four of water. Nine elements are placed in one cell within a box. Each car carries two similar boxes, with a commutator to allow the elements to be grouped by 14 or 18. Each compartment has two lamps—one plain and the other red—the latter being lighted automatically when the white lamp fails. An hour-meter is attached to indicate the time the lamps are burnt, and consequently when the batteries require recharging. The 18 elements weigh 120 kg. (264lb.), and will light the three lamps of the car for 48 hours, lighting at 10 volts and 1·6 amperes. The experiments have, however, been abandoned.

Electrolytic Production of Zinc.—A process has been developed for converting blende (sulphurated zinc) into soluble salts of zinc and electrolysing the latter in an electrolytic bath. The cathode is formed of zinc or another metal not affected by the process; the anode is of iron or other metal not zinc. The electrodes are separated by a porous partition. The cathode is surrounded by a water solution of a zinc salt; for instance, sulphate of zinc obtained from sulphurated zinc by chemical or metallurgical means. The anode, on the other hand, is surrounded by a solution whose positive component is a salt of the metal employed as anode, and whose negative component is of the same acid as that in the zinc salt to be electrolysed. When the liberated acid forms during electrolysis insoluble salts by combining with the anode, the above-mentioned porous partition is suppressed, and both the cathode and anode are surrounded by the zinc salt to be electrolysed.

A Castle in the Air.—The great exhibition which is to take place next year at Antwerp will boast a literal castle in the air. A company has been formed to carry out the plan of M. Tobianski, an ingenious engineer, who has designed a sort of raft, having an area of about 180 square feet, and made of bamboo canes and steel and aluminium piping. Upon this is built a most luxuriously fitted-up restaurant. The raft is held floating in the air 500ft. above the ground, by a number of balloons; and an arrangement of anchoring by means of cables will (so says M. Tobianski) prevent the restaurant from rocking even in the strongest wind. Two small captive balloons, each holding from eight to ten persons, will serve like lifts to keep up communication between the aerial restaurant and the earth. There is a regular system for supplying gas to the balloons, and at night the exhibition will be lit up by an immense electric light projected from the raft. The whole thing can be lowered to the ground within 10 minutes by specially constructed windlasses.

Conjoint Resistances.—A simple method of measuring conjoint resistances of circuits is given by Mr. W. C. Ramsdell (New York *Electrical Engineer*), often preferable, he considers, to the usual methods (*a*) of dividing the product of their resistances by the sum (any two conductors at a time), or (*b*) the "reciprocal" method, which is to add the reciprocals of the resistance of each conductor, and the sum is the reciprocal of the joint resistances. By the third method (not hitherto published, he thinks) the conjoint resistance is found by dividing an assumed E.M.F. by the sum of the currents which would be produced in the given conductors, thus

using nothing but Ohm's law. The calculation is simplified by taking an E.M.F. which is a common multiple of the resistance. Thus, given five conductors of 2, 3, 4, 5, and 6 ohms respectively, to find their joint resistance. The least common multiple is 120: then, assuming 120 volts, there would be currents of 60 40, 30, 24, and 20 amperes. The sum of these is 174 amperes and $120 \div 174 = \frac{20}{29}$, which is the joint resistance of the five conductors. The superiority of this method is quickly seen when the attempt is made to calculate the joint resistance by either of the old methods.

Electrolytic Action on Water-Pipes.—One of the pressing questions which are being discussed in America is that of the electrolytic action by the current from trolley tramways on the gas and water pipes. There seems to be real cause for anxiety according to certain accounts of accidents which have already happened. In Illinois, an overhead line became grounded through one of the iron poles carrying the span wires. The base of this was in contact with an abandoned cast-iron gas-pipe, both being somewhat rusted. In crossing, an arc was formed, practically welding the two together. It is said the current then followed the old pipe 100 yards, where the cast-iron pipe encountered a wrought-iron natural-gas main. Here the same thing occurred: the pipes were melted and an opening formed so that the gas entered the old pipe, which followed to the base of the iron pole. Here it caught light and issued at the top in a flame 15ft. high, quickly melting the trolley lines and interrupted the traffic. This accident was more due to the heating effect than to electrolysis. But in Battle Creek, Michigan, a wrought-iron coated service pipe (water) taken from the earth in front of the street railway power-house, 3ft. below surface, showed an extraordinary appearance. It was eaten to bits with large irregular holes all over it. The tramway system was the usual overhead trolley with grounded circuit, having been in operation 18 months.

Gas-Engine Generators at Lille.—The day of large gas-engine plants seems beginning. We have one or two examples in England, and in Lille, in France, there is a typical example. The Société Lilloise d'Eclairage Electrique will have for its station plant three Otto gas-engines of 110 h.p. to 120 h.p. Each engine will drive two Rechniewski direct-current dynamos. A battery of accumulators, with a normal output of 50 kilowatts, will be installed. Each dynamo will give 288 amperes at 125 volts, or 36 kilowatts. The mains will be underground on the three-wire system. The cables will be heavily insulated and double-armoured, and laid in a thick bed of sand. At crossings culverts will be formed. There will be three sets of feeders. The pressure will be 114½ volts to give 110 volts with a drop of 4½. The choice of gas for motive power has been brought about by an able paper by Prof. Witz, of Lille, which went to demonstrate that gas-motors would one day supplant steam-engines, and that at present there is not economy, but the reverse, in using steam-engines. There is also the reason that the town has a royalty of $\frac{1}{10}$d. per cubic metre of gas sold, which doubtless told towards the choice of gas-engines. The larger streets of Lille will be lighted by arc lamps, and there is a good field for private lighting. Engineers discussing different systems of plant would do well to keep informed of the progress of this installation.

Nantes.—The town of Nantes has been recently lighted by electric light on the low-tension system with accumulators. The batteries are placed in sub-stations, and the distribution is on the three-wire system. The generating station is in the Rue Sully, about 160 yards from the small river Erdre. The dynamos are five in number. Three engines are used—one of 75 h.p., Weyher et Richemond, and the two others, of 120 h.p., were made by Voruz, of Nantes. The engines are coupled to the dynamos by Raffard couplings. The 75-h.p. engine drives a dynamo giving 200 amperes at a pressure varying from 250 to 330 volts; the two other machines drive dynamos giving 270 amperes at the same voltage. The current from each machine is taken to a switchboard, whence it can be sent either to the accumulators at the sub-station in the Rue Calvaire or to the station battery. The batteries at the two stations together can supply 1,000 amperes at 220 volts for three hours, which is sufficient for 6,000 10-c.p. lamps. The total number of lamps is 8,000, but never more than 70 per cent. are lighted at the same time, and the accumulators can therefore easily supply the lighting for one evening. The engines are only run during a portion of the day. The mains are entirely underground; bitumen conduits take the three-wire conductors and a feeder. The service mains, in iron pipes, are connected direct to the mains; a service box contains two fuses at the junction.

Electro-Metallurgy.—The Central News says: "At the Institute of Mining and Metallurgy, Jermyn-street, on the 28th ult., Mr. J. D. Hannay, of Cove Castle, Loch Long, laid before the members the last instalment of the scheme of metallurgy which he has been unfolding for some years, and one branch of which he recently communicated to the Royal Society. The paper dealt with the refractory ores of gold, which, now that alluvial deposits have been wrought out, constitute the whole future source of gold. Mr. Hannay remarked that in all our colonies mines yield refractory ores as they reach deeper levels, and the impossibility of extracting their gold at a reasonable cost had driven many miners to the conclusion that the prosperous period of gold-getting was over, but as the gold is there in as great a quantity as ever, although beyond the reach of known processes, chemists have always hoped by some simple discovery to extract the gold cheaply, and thus renew the palmy days of early prosperity. The process which Mr. Hannay described, and by which at the cost of a few shillings per ton, he can electroplate the gold out of any ore in a few hours, offered, he maintained, a complete solution of the modern difficulty. The apparatus was described as being of extreme simplicity, one vat being capable of exhausting 10 to 20 tons of ore in three to four hours, while the gold and silver are all obtained in the metallic state as an amalgam. The process, as shown by tests made by the assayer to the Bank of England, deals so efficiently with ores of every degree of refractoriness that any variation in the ore—common occurrence in the course of mining—does not affect the yield of gold by this process."

Omnibus-Lighting.—The views of Mr. Freund, as expressed in his paper before the Tramways Institute, must be taken with caution. For the past 12 or 14 months we have narrowly watched the experiment of lighting London omnibuses. Two firms are doing this work—viz., Mr. Bristöl and the Lithanode Company. Unfortunately, neither of these firms have issued an authoritative statement as regards the actual cost of the work. Indeed, the Lithanode Company is not in a position so to do, as the apparatus manufactured by it was manufactured simply to the order of Mr. Willing, who contracts for the lighting of certain 'buses. All that the Lithanode Company has done has been to charge the batteries for a certain payment per week. We are told that the batteries used act admirably, and the plates used are mechanically and electrically as good now as when put in. So far as we can gather, Mr. Bristol

hires out his apparatus, and has not sold any. Therefore he would be in an excellent position, if he chose, to give an authentic history of the total cost: initial, maintenance—everything; also the communications which have passed to and from him with regard to the light. Rumour says the matter is not quite satisfactory; but it would be advantageous to have facts—not rumours. The estimate as given by Mr. Freund is to our mind misleading. One item can be checked, and if on so important a point there is incorrectness, we must take it that the estimate is merely an estimate, and intended to attract rather than to prove. Can any incandescent lamps be supplied at 1s. 6d. each in this country at the present time? If, then, there is an error in this one item alone of from £60 to £70, what value can we place on the whole estimate? It is not assisting the industry to promulgate information that cannot be substantiated, and these statements make it doubly hard for legitimate traders to do real business.

Electric Traction and the Telephones.—Mr. F. F. Bennett, of Preston, in a letter to the *Manchester Guardian* recently, gives a number of statistics as to the cost of working telephone stations. He suggests that any corporation, in return for allowing a company to put its wires underground, should have their telephones free. He then deals with the question of interference, saying: "If we are in this country to enjoy the great advantages of electric traction, I consider that there is no alternative but to have a complete reconstruction of our telephone system. The present obsolete method must give way to the more modern and perfect one of metallic circuits, thus ensuring the electrical non-interruption of both industries, and so improving that of the telephone as to entirely do away with bad speaking, overhearing, noises, and other inductive abominations. It is assumed that the difficulty can be overcome by the electric traction people using a metallic return, but there are considerable practical difficulties in the way of this. My own experience goes to prove that where a centre underground channel is used containing one conductor with an earth return great trouble is experienced in keeping that bare conductor properly insulated. In the case of the Blackpool tramway short circuits were occurring at first very often, especially when the collector or slipper passed over junction and facing points. By dint of dogged perseverance this trouble was subsequently reduced to a minimum, and now similar faults very seldom occur. Imagine, therefore, the difficulty of coping with two underground bare conductors (which must be kept highly insulated and in close proximity) instead of one. It may be argued that one of the conductors could be placed overhead on the American plan. Assuming that this would get over the difficulty, I am certain that it would not be allowed by the ruling municipal authorities." In conclusion, Mr. Bennett draws attention to the fact that the Post Office are about to acquire the trunk wires over the kingdom, so that no difficulty would be likely to arise in the matter of inter-town communication in the event of other companies forming, as the Post Office would allow facilities for trunk-wire speaking to all."

Ayrton and Mather's Galvanometer.—The new form of d'Arsonval galvanometer, devised by Prof. Ayrton and Mr. Mather, is fully described in its practical form in the price-list issued by Mr. R. W. Paul, of Hatton-garden. There are several points of much interest in this moving-coil reflecting galvanometer, and we see that a number of them have been supplied to the technical colleges—Cambridge, Nottingham, Liverpool, Manchester, etc.—to the physical science professors. A coil of wire hangs in a powerful field whose lines are parallel to the plane of the coil, on passing a current through the suspensions the coil is deflected through an angle which depends on the strength of the current. A very long, narrow coil, of cross-section of two circles touching, is adopted on mathematically-determined principles. This coil is for a dead-beat instrument, enclosed in a tube of silver; when it moves, the Foucault currents generated tend to bring it to rest. For a ballistic galvanometer no such tube is used. The suspension has been carefully tested to avoid tilting, the system adopted being to have the coil freely suspended from above, while the continuity of circuit is maintained by a light flat strip spiral attached to an insulated pin at the lower end of the coil-tube. An outer brass tube protects from injury, and a clamping device enables the galvanometer to be easily transported. A substantial brass base-plate carries the whole, furnished with levelling screws. A strong permanent magnet is bolted thereto in the form of a cylinder: it bears a circular spirit-level for adjustment. Interchangeable coils are supplied. The radius or scale distance of the mirror is usually 3ft. The stock pattern, having an aperiodic coil of 325 ohms resistance, gives with one-millionth of an ampere about 10 millimetres deflection on the scale at one metre distance. Greater sensitiveness can be obtained, but this is amply sufficient for all ordinary purposes. The ballistic coils have a period of about three seconds. By winding the coils with two similar wires, through which currents can flow in opposite directions, a very sensitive galvanometer is produced in which the slightest difference of current in the coils gives a large deflection. Scales, keys, and shunt-boxes are also supplied for the various tests carried out by reflecting galvanometers. The price is very low compared with some forms, and the size in travelling-case is about 7in. cube. It is an exceedingly useful form of reflecting galvanometer.

Artistic Fittings.—"A thing of beauty is a joy for ever," sang Shelley in one of his best-known lines, and nowhere is it more true than in one's house. To be able to live with it is the supreme test of a good picture, and it is the same with the house decorations. We have often dwelt upon the desirability of electrical contractors cultivating to the utmost the æsthetic side of their work. It will be found to pay to have a skilled decorator of high taste to consult with the heads of households, as well as an engineer whose evident knowledge of exact requirements inspires confidence in the machinery. Among the producers of highly artistic electric fittings the firm of Lea, Sons, and Co., of Shrewsbury, have for some time taken high place. Glimpses have been seen in showrooms and exhibitions of delicately-wrought leaves and sprays prettily adapted to electric light. The firm have issued a catalogue very handsomely and carefully arranged. The designs are printed in silver and gilt toned ink on separate sheets, and each design is hand-tinted in their colours. The result is charming from the catalogue point of view, and put into the hands of any lady of the mansion must make her long for her house to be so fitted. When this stage arrives the battle is over; and when a person is thinking of having electric light, designs of this kind are just those to bring the thought to a resolution. Several sheets of simple designs are given, but those shown on sheets 1 and 4, for instance—china painted jar with metal wrought sprays and electric flowers, candle-brackets, leafy pendants, and standards—are fine specimens of the floral electric fitting. There are several styles—the metalli-floral may be varied with the cord pattern, where the electric globes hang on gilded cords from delicately-wrought pendants in metal. The lists are only an indication of the wealth of designs that can be furnished. All the fittings are wired so that the wires can be withdrawn for inspection or repair. A

ball or hollow body usually supports the arms; inside the ball are metal rings on a vulcanite or slate base, to which the wires are attached, and when the upper half of the ball is raised the wiring is exposed. The fittings are made in iron (black or bright), bright iron and blue steel—a very artistic combination—polished brass, brass and copper, gilt and silver. We notice that a spray of any metal or combination will be sent on application at 5s. a spray, so that colours and effects can be tested. This list of fittings is one which should be in the hands of all who fit up high-class houses.

Electro-Photography.—Mr. David E. Packey, of Birmingham (who writes his experience in the *English Mechanic*), thinks he has discovered a new science—a "new field of astrophysical research." This is in photographing the "electric rays" of the spectrum. He does this by causing an electric current to pass over the photographic negative during exposure, and he obtains a "secondary spectrum." The ordinary spectrum is very slightly deflected by the current; but on development a second faint spectrum is seen of rays wholly contained in the ultra violet portion beyond the H and K lines considerably deflected by the action of the current. It is so faint that the other portion must be considerably over exposed to develop it. This secondary spectrum he has denominated the "electrical spectrum," the action of the current "tending to deflect all rays in the sun's light due to electric energy, and so isolate them from the rays due to chemical energy, and always in a direction parallel to the current. When the electric current was applied to a sensitive plate exposed to the image of a star's light, and stationary so as to form a trail, the resulting image was somewhat deflected from its normal position whenever the circuit was complete, returning to its normal position when the circuit was broken, and showing an increased intensity in the chemical action at the ends of the broken trails." The method adopted of causing the current to affect the plate was by placing the sensitive plate with its film side away from the object-glass, and backing the film with a sheet of tinfoil, the ends of which, projecting from the movable back, enabled a connection to be easily made with the wires of a battery, and thus completing the circuit. A single two-volt cell with zinc and carbon elements completed the apparatus employed. The plates were developed in the ordinary way with hydroquinine. Every care was taken to prevent any false images due to reflections, halation, etc., from being confounded with the electrical images. Photographs were taken of the same objects without the interference of the current as a check on the results obtained. The idea in these experiments is, apparently, that if there is any definitely electrical action in photography it will be deflected by a steady current at right angles; there would then be a sifting of the various rays, and comparison might give extra data for study of star distances. Any celestial photograph would thus have double value. There is something hazy in the reasoning; but if there is such an effect as deflection of spectrum rays by a current, this phenomenon requires studying.

Effective Alternating Currents and Electromotive Forces.—Mr. A. E. Kennedy (in the *Electrical World*) gives some clear remarks on the terms "mean current," "square root of mean square," and "effective current," as applied to alternating-current circuits. Suppose, he says, that in a circuit we have a current alternating between the limits of 10 amperes positive and 10 amperes negative, say, 200 times in a second. The mean or numerical average current strength will be some value between 0 and 10, depending upon the shape of the current wave. With a simple zigzag wave, the mean current would be 5 amperes, for semicircular waves 7·854 amperes, and with sine waves 6·367 amperes. But in the most important practical applications of electric currents, the effect depends upon the square of the current strength. The rate of developing heat in a constant resistance is a prominent instance, and incandescent lamps may be practically included in the same category. When the current through such a resistance is doubled, the rate at which the heat is generated therein is quadrupled. If the current periodically alternates or fluctuates, the same quantity of heat will be developed in a given interval of time (including many cycles), if the average square of the alternating current is equal to the square of the uniform continuous-current strength. Just what maxima the cycles will reach when this condition is maintained will depend upon the shape of the current wave; but if the wave happens to be a sinusoid, with a maximum of 10 amperes, whose square is 100, the mean square over the cycle is just half this maximum square, or 50, and the heating effect of this alternating current would be equal to that of a continuous current whose square was 50—that is, whose strength was 7·07 amperes. The "effective" strength of any fluctuating or alternating current is thus the square root of its average square, and if we know this effective strength, we know the heating power of the current without requiring any knowledge of the wave shapes. The mean strength of a current measures, then, the quantity of electricity that would flow through the circuit in a given time, without regard to direction. The "effective current," or square root of the mean square, measures the thermic activity that the current will develop in a resistance. The mean strength of an alternating current would be indicated by a D'Arsonval galvanometer if the waves were all "rectified," or delivered to it in the same direction with the aid of a commutator. The "effective" current strength would, on the other hand, be indicated by an ammeter of the dynamometer type, with or without rectification, since the deflections of such instruments are independent of the direction, but proportional to the square of the traversing current's strength. If this square fluctuates, they point out the average square. Similarly, the "effective" voltage of a periodically varying E.M.F. is equal to that uniform continuous E.M.F. which, applied to a simple non-inductive resistance, would generate therein the same amount of heat in a given time sufficiently long to include a number of cycles and obtain a fair average. Since the thermal activity of an E.M.F. applied to a fixed resistance is proportional to the square of the voltage, the effective value will be the square root of its average square. The term "effective," chosen by the Paris Congress of 1889, may be understood as "effectively equivalent in thermal activity." All alternating-current voltmeters and ammeters are in practice calibrated to "effective values." By this means an incandescent lamp which is brought to full illumination on a continuous-current circuit by half an ampere, or by 100 volts, will be brought to full illumination by these same quantities of current and voltage on an alternating-current circuit, no matter what the shape of wave, assuming, of course, as experiment shows we may, that the "skin effective" and the induction in the lamp filament are negligible. If, on the other hand, alternating current apparatus were calibrated in "mean" values, the voltage or current necessary to supply lamps at normal candle-power would not only differ from the corresponding continuous-current values, but would also depend upon the shape of the alternating waves

ALTERNATE-CURRENT TRANSFORMER DESIGN.

BY R. W. WEEKES, WHIT.SCH., A.M.I.C.E.

(Continued from page 622, Vol. XI.)

Third Design.—In this, the last transformer to be designed, we will make the mean lengths of the copper and iron circuits nearly equal. The first design had a short copper circuit and a long iron core; then in the second these relative proportions were reversed and the iron circuit was short. Now, the mean length of the turns in the copper circuits and the length of the path of the magnetic lines will be, roughly, the arithmetical means of the respective values in the two previous designs. This gives a transformer of the type used by Ferranti, in which a rectangular core of iron is surrounded by rectangular formers containing the copper conductors.

Assuming the core to be 9in. long by 3in. broad, and the length of winding formers to be about 9½in., we can roughly estimate the weight of iron in the transformer, Figs. 19 and 20. The cross-section of the iron equals 85 per cent. of 27 square inches = 23 square inches, or 148 square centimetres. The length of the iron circuit cannot be accurately determined till the winding has been fixed, but will be, roughly, 28in., so that the volume of the iron = 23 × 28 = 642 cubic inches and weighs 180lb. The iron loss allowed is 150 watts, so that the loss per pound = $\frac{150}{180}$ = ·835 watt. The curve of total iron losses, Fig. 4, shows that this

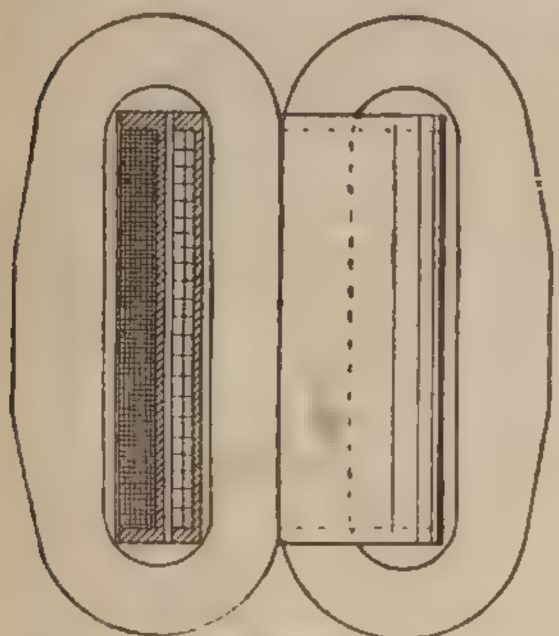

FIG. 19.

corresponds to an induction of about 3,500 lines per square centimetre. The core area being 148 square centimetres, hence the total flux equals 148 × 3,500 C.G.S. lines, ∴ F = 518,000.

Designing the secondary winding first from (1)

$$e_2 = 4{\cdot}45\ F\,\tau_2\,n\,10^{-8},$$

and allowing 102 volts to make up for the drop due to copper loss at full load, we get

$$102 = 4{\cdot}45 \times 518{,}000 \times \tau_2 \times 100 \times 10^{-8};$$

$$\tau_2 = \frac{102}{4{\cdot}45 \times {\cdot}518} = 44{\cdot}2 \text{ turns.}$$

We must have an even number of turns, as two layers will be the most convenient method of arranging the secondary strip—44 being the nearest even number, will do well for the number of turns in the secondary. The primary turns can now be calculated from

$$\tau_1 = \frac{\tau_2 \times 2{,}000}{102} = \frac{44 \times 2{,}000}{102},$$

$$= 865.$$

In this type of transformer the coils are usually wound separate formers and slipped on individually. The question of which should be nearer the core has been often discussed, and the balance of advantage appears to lie in placing the secondary next to the iron, as then the high volt winding is farther from the iron, and less likely to leak to earth. Also, the thick wire of the secondary is wound on a smaller former, and is hence more stable. The question of eddy currents in the copper due to leakage of magnetic lines from the core out through the copper has been urged as a reason for putting the thick wire outside. With certain strained assumptions as to leakage and copper weight, this appears to be a valid reason but for the fact that the eddy-current losses in the copper are so small as to be negligible in most transformers. Assuming the leakage to take place radially from the core, the induction and hence the eddy-current loss per unit volume of copper, is greater near the core. But the volume of copper required increases more rapidly than the perimeter of the winding if a constant full load drop is allowed, and so the increase of volume varies almost as the square of the perimeter. This increase in volume or weight of conductor balances the decrease in the density of the leakage field, and keeps the Foucault loss constant. Hence there is no disadvantage from leakage caused by winding the thick wire near the core. Placing, therefore, the secondary inside, it is necessary to design it first, as its thickness will affect the perimeter of the primary.

The clearances between the insulating cylinder and the iron must be slightly more than in the previous design,

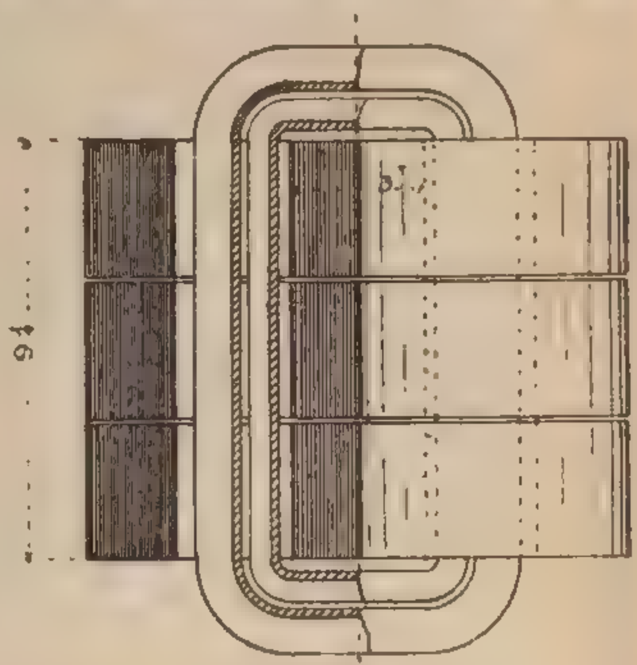

FIG. 20.

owing to the method of core construction used. Fig. 20 shows the general outline of the coils, and from it the mean perimeter of the secondary equals 2·37ft. The total length of the insulating cylinder being 9½in., we shall get about 8½in. for winding space. The section of the tape to be used is got from (3)

$$s = \frac{i\,\tau_2\,\pi_2\,9{\cdot}2}{\theta}\,10^{-6};$$

and $i = 60$ $\pi_2 = 2{\cdot}37\text{ft.}$

$\tau_2 = 44$ $\theta = 1.$

$$\therefore\ s = 60 \times 44 \times 2{\cdot}37 \times 9{\cdot}2 \times 10^{-6};$$

$$= {\cdot}0572 \text{ square inch.}$$

The tape had best be wound in two layers of 22 turns each, so that the insulated tape should measure $\frac{8{\cdot}5\text{in.}}{22}$, say, ·385in., in order that 22 turns may be wound in 8·5in. Uninsulated the copper would be about ·350in. broad, and to give the section must be ·165in. thick. Tape (·350in. × ·165in.) will therefore be used, and the two layers will give a total depth of winding of ·4in.

Calculating the resistance as in previous designs for the exact section of the tape, ·0577 square inch, we get from

(3) that $r_2 = \cdot 0166$, which, with 60 amperes, gives just under the one volt drop allowed.

The weight of copper from

$$g = S\,\tau\,\pi \times 3\cdot 85,$$

by substituting the proper value for the symbols becomes

$$g = \cdot 0577 \times 44 \times 2\cdot 73 \times 3\cdot 85\,;$$
$$= 23\text{lb.}$$

The clearance between the outside of this secondary winding and the primary cylinder must be sufficient to allow the latter to be slipped on. The space left is by no means wasted, as it provides ventilation to the wires in the centre of the coil. In fact, with a transformer so placed that these cylinders are vertical, the chimney action in these air spaces between the windings is most useful in cooling the wires. This space and the necessary thickness of cylinder and wire raises the mean perimeter of the primary wire to about 2·87ft. This is the only remaining unknown quantity in the equation for the diameter of the wire :

$$d = \sqrt{\frac{i_1\,\tau_1\,\pi_1\,11\cdot 75}{\theta}}\,10^{-3},$$

the other values being as follows :

$$i = 3\,;\ \tau_1 = 865\,;\ \pi = 2\cdot 87\,;\ \theta = 20\,;$$

$$\therefore\ d = \sqrt{\frac{3 \times 865 \times 2\cdot 87 \times 11\cdot 75}{20}}\,10^{-3}$$
$$= \cdot 066\text{in.}$$

So 66-mil wire will give the 1 per cent. loss, and it can be wound in eight complete layers of 100 turns and one layer of 65 turns. In between each layer it will be necessary to place a sheet of insulating material, as there will be a difference of potential of about 470 volts between adjacent wires in different layers at the ends of the coils. This extra insulation will increase the depth of the winding to about ·85in. The resistance of the wire from (4) is

$$r = \frac{\tau_1\,\pi_1\,11\cdot 75}{d^2}\,10^{-3}$$

$$= \frac{865 \times 2\cdot 87 \times 11\cdot 75}{\cdot 066 \times \cdot 066}\,10^{-3}$$

$$= 6\cdot 68 \text{ ohms.}$$

The weight of conductor, from the formula following the above, works out to 32·7lb. These calculations complete the design of the copper circuits.

With the Ferranti system of building up the core and yoke, the question of winding space does not affect the calculations so much. It is necessary first to design the coils to suit the core area allowed, and then to get out the length of plates required to encircle these coils with ample clearance. Leaving the actual details of construction till later, we can, from Fig. 19, get the mean length of the iron circuit, which is 28·5in., or 72·7 centimetres. The cross-section of iron was 23 square inches, so that the exact volume will be 656 cubic inches, weighing 183lb. The total field, F, required when $\tau_2 = 44$ will be 520,000 C.G.S. lines, so that $\mathfrak{B} = \frac{520{,}000}{148} = 3{,}520$. The loss per pound in watts at this induction for the iron assumed by curve, Fig. 4, is ·827, so that the total iron loss $= \cdot 827 \times 183 = 151$ watts. The watt current, i_H, required to give this power at 2,000 volts $= \frac{151}{2{,}000} = \cdot 0756$ ampere.

The next step is to determine the μ current from $i_\mu = \frac{\mathfrak{B}\,l}{\mu\,\tau_1\,1\cdot 76}$.

In this transformer $\mathfrak{B} = 3{,}520$;
$l = 72\cdot 7$ centimetres;
$\mu = 1{,}950$ from curve, Fig. 5;
$\tau_1 = 865$;

$$\therefore\ i_\mu = \frac{3{,}520 \times 72\cdot 7}{1{,}950 \times 865 \times 1\cdot 76}\,;$$
$$= \cdot 0864 \text{ ampere.}$$

Now i, the magnetising or no-load current,

$$= \sqrt{i_H^2 + i_\mu^2},$$
$$= \sqrt{\cdot 0756^2 + \cdot 0864^2},$$
$$= \cdot 115 \text{ ampere,}$$

which is 3·83 per cent. of the full-load primary current.

Collecting all the figures into a list.

Six-Kilowatt Transformer—Third Design.—Ratio of transformation, 2,000/100 volts; $\frown\!\smile = 100$.

Core, 9in. × 3in.; area of cross-section of iron, 148 square centimetres.

$\mathfrak{B} = 3{,}520$; F = 520,000; $l = 72\cdot 7$cm.

Primary: $\tau_1 = 865$; $\pi = 2\cdot 87$ft.

Wire, 66 mils diameter, wound in eight layers of 100 turns per layer and one layer of 65 turns per layer.

$r = 6\cdot 68$ ohms, hot; loss = 1 per cent.; weight, 32·7lb.

Secondary: $\tau = 44$; $\pi = 2\cdot 73$.

Conductor used, tape (·350in. × ·165in.), wound in two layers of 22 turns each.

$r = \cdot 0166$ ohm, hot; loss, 1 per cent.; weight, 23lb.

Losses—Iron	151 watts ...	2·51 per cent.
Copper, primary...	60 „ ...	1·0 „
Copper, secondary	60 „ ...	1·0 „
	271 watts	4·51 per cent.

The efficiency at full load being

$$\frac{6{,}000}{6{,}271} = 95\cdot 7 \text{ per cent.}$$

Magnetising current = 3·83 per cent., so that the load factor, or ratio of true watts to apparent watts on open circuit, equals ·657.

The weight of iron =	183lb. at 4d. per lb. =	61s.
„ copper =	55·7lb. at 10d. per lb. =	46·5s.
Total............	238·7lb.	107·5s.

Which gives 39·8lb. and 18s. per kilowatt output.

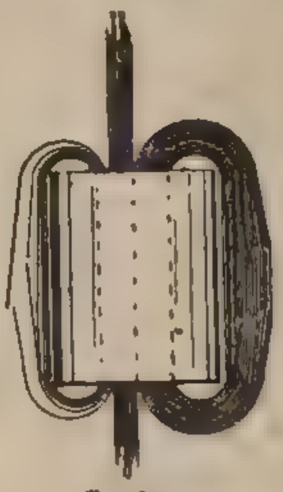

Fig. 21.

The ratio of weight of copper to weight of iron equals $\frac{55\cdot 7}{183} = \cdot 304$.

The effective cooling surface of this transformer is difficult to estimate correctly, and comparisons made on the basis of the watts wasted per square inch total external surface will not afford a true idea of the heating limits. This is caused by the number of ventilation spaces running right through both the copper and iron circuits, which by their cooling effects greatly assist the external surfaces. The surface which is exposed externally amounts to only 750 square inches, and hence the watts per square inch work out to $\frac{271}{750} = \cdot 362$ at full load, and to $\frac{151}{750} = \cdot 201$ at no load.

The method of construction of the iron circuit is explained in Fig. 21. In this transformer, as designed, the iron

used consists of strips 3in. broad, arranged in three parallel bands, Fig. 20. This is done to facilitate the bending of the plates, and also to give increased ventilation through the iron. Also, it tends to reduce eddy currents in the iron if any appreciable magnetic leakage takes place out from the core through the broad plates. These strips of iron are cut to various lengths, as shown in Fig. 21, and laid out perfectly straight with alternate plates projecting each way. Then the formers containing the conductors can be slipped on over this rectangle of iron and secured in the centre of it. The next step is to bend the plates individually into their final positions. The reason of having them with alternate intervals at the ends is to secure that they break joint at the centre of the yoke. This keeps the magnetic resistance low, as explained in other designs. The weight and cost of this transformer will be found to compare favourably with those of the two previous designs, but it will not be correct to say from this that the type is the best. Until the best design of each type has been definitely fixed it is misleading to institute comparisons. So in this case the effects of less iron and more copper should be carefully investigated.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC.MEM.INST. ELECTRICAL ENGINEERS.

ARC LIGHTING.

(Continued from page 623, Vol. XI.)

The direction of path of a ray of light emanating from a source is defined by its "angle of incidence." The angle of incidence signifies the angle that the ray in question makes with a vertical line dropping down from the centre of the source of light. The top diagram in Fig. 25 illustrates rays having angles of incidence of 30deg., 45deg., 60deg., 70deg., and 80deg., the horizontal line being, of course, a right angle, or 90deg. They also show at what points they touch the ground-line for various heights of the lamp. A, B, and C denote three different ground-lines, thus giving the arc three different heights, in the ratio of 1, 2, 3. The innermost ray of the belt of maximum light previously mentioned has evidently an angle of incidence of 30deg., because 60deg. below the horizontal is the same as 30deg. out of the vertical. Similarly, the outermost ray has an angle of incidence of 60deg. These two angles of incidence are drawn in thick lines to mark the borders of the belt, and the base which lies between the borders is shaded for the three ground-lines, A, B, C. It will be noticed that the ray having an angle of 80deg. touches the ground-line some distance from the lamp; in addition to this, the light given at that angle is much below the maximum, so that the illuminating power is only feeble: therefore it is not worth while receiving rays that have an angle of incidence greater than 80deg.

An arc lamp forms an elevated centre of the illuminated circle, and it is interesting to examine into the relations between heights and distances, etc. We will assume that the arc is at such a height that the farthest point to be illuminated is reached by a ray having an angle of incidence of 60deg.

Let the height of the arc above the ground be, say, 10ft., as shown by the line, $b\ c$. Then, since the farthest point illuminated is where the ray of 60deg. reaches the ground, hence the horizontal distance, c P, will represent the radius of the illuminated circle. This distance, c P, we will call the "radius distance," to distinguish it from the angular distance, b P. Knowing the angle and the height, it is easy to find the radius distance, which is obtained from the formula :

Radius distance = height × tan A ;
also, Height = radius distance × cotan A,

where tan A and cotan A represent the tangent and cotangent of the angle of incidence of the ray. In the present case the angle of incidence is 60deg., and the values of tan 60deg. and cotan 60deg. are respectively 1·73 and ·578. *Inserting these values, we have*

Radius distance = height × 1·73,
and Height = radius distance × ·578.

So if the height, $b\ c$, be 10ft., then the radius distance, c P, will be 17·3. The length of the path of the ray can also easily be found when the height and the angle is known, since it equals the height divided by the cosine of the angle of incidence. Now cos 60deg. is ·5 ; hence 10 ÷ ·5 = 20, so that the path of the ray denoted by b P = 20. It may be put down as a rough rule that an arc will illuminate well for a radius distance equal to double its height, because no rays beyond 64deg. are then required.

Rays having an angle of 80deg. will illuminate at a radius distance equal to about five and three-quarters the height of the arc from the ground. For a ray at a fixed angle, its radius distance and its length of path will be directly proportional to the height of the lamp, but if the candle-power remains the same, the illuminating power of the ray where it reaches the ground will diminish very considerably as the height of the lamp increases. In the lower diagram of Fig. 25, when the height, $b\ c$, is 10ft., the radius distance, c P, is 17·3ft. for a ray of 60deg. as shown, and the length of the path of the ray, b P, is 20ft. Suppose at the point, P, where the ray falls on the ground that the illuminating power or intensity of the ray is equal to 10 c.p., allowing that the light given off the arc

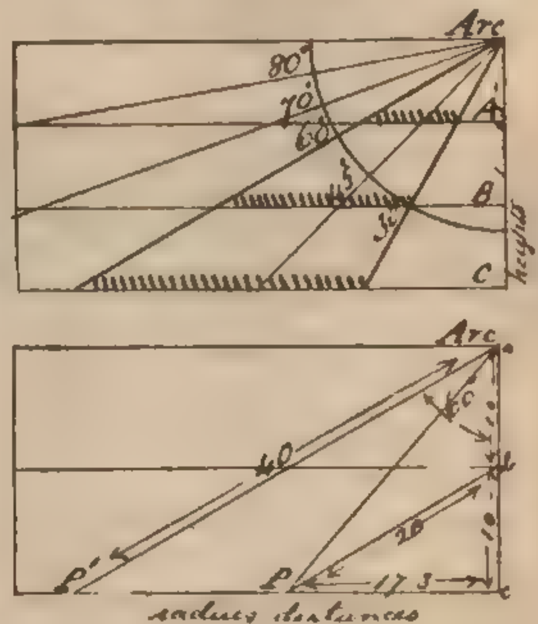

FIG. 25.

at this angle is three-quarters of the maximum ; now double the height of the lamp, making it 20ft., the length of the path of the ray will now be doubled and the new point, P', where it reaches the ground will be 40ft. away from the arc. The intensity of light varies inversely as the square of the distance from the source of light, and since the distance is doubled it follows that the intensity will be only one-fourth, and so the candle-power at P' will be 2·5. From this it is seen that the candle-power of a ray at a fixed angle varies inversely as the square of the height of the lamp at the point where it touches the ground. Now, instead of keeping the angle of the ray constant, keep the same point, P, under consideration when the height is varied ; then, when the height of the lamp is doubled, the angle of the ray falling on the same point, P, will be much smaller. To find how the intensity alters at the point, P, we must first obtain the lengths of the two paths, P b and P a. P b = 20, and P a = $a\ c$ ÷ cos P $a\ c$. We have now to find out what the new angle P $a\ c$ is. To do this, we already know that the radius distance ÷ height = tan of the angle of incidence, therefore P c ÷ $a\ c$ = tan P $a\ c$; that is, 17·3 ÷ 20 = ·865 = tan 41deg., nearly. Having now obtained our new angle, all that is wanted is the length of the path P a, and, as given above, P a = $a\ c$ ÷ cos 41deg. = 20 ÷ ·754 = 26·5 ; so that the path P b, representing the old ray of 60deg., is 20ft. long, while the path, P a, of the new ray of 41deg. is 26·5ft. long. The intensity varies inversely as the square

of the distance, hence the candle-power at P, when the height of the lamp is 20ft., will be $10 \times 20^2 \div (26 \cdot 5)^2 = 4{,}000 \div 702 \cdot 25 = 5 \cdot 7$ about.

Finally, we must make a correction, because the light given by a ray of 41deg. is of greater intensity than what is given by a ray of 60deg., other things benig equal. At 60deg the light was assumed to be three-quarters of the maximum, and at 41deg the light may be taken to be almost at the maximum, so $5 \cdot 7 \times 4 \div 3 = 22 \cdot 8 \div 3 = 7 \cdot 6$ = candle-power at the point P, when the arc is at *a*, or 20ft. high.

Consumption of Carbon.—It will be found in practice that the positive or upper carbon burns away at twice the rate at which the negative or lower carbon does. The proportions are not exactly 2 : 1 ; in different lamps and with different kinds of carbons the proportion varies slightly, but, as a rule, they will all come pretty close to the above ratio, and when trimming, the lamp trimmer always allows double the length of positive to the length of negative. The writer obtained the following rate of consumption of carbon, being the average of a number of tests made on a Brockie Pell "full" arc lamp:

Positive carbon, $\frac{5}{6}$, or ·833in. per hour.
Negative „ $\frac{3}{8}$, or ·375in. „
Current being 10 amperes.
Pressure being 40 volts.
Energy consumed by lamp being 400 watts.
Diameter of carbons being 13mm.

With a full arc lamp, or one taking 10 amperes, the best size of carbons to use is 13mm., or $\frac{1}{2}$in., in diameter. With a half arc, or one taking six to seven amperes, carbons of 11mm., or $\frac{7}{16}$in., in diameter, should be used ; for a small lamp taking only five amperes, say, about 9mm. is suitable, whilst for a very powerful lamp, such as a searchlight of 25,000 c.p., and taking a current of probably 50 amperes, the size would be about 24mm., or close on 1in., in diameter. The rate of consumption of these larger-sized carbons is less than the smaller sized ones, the burning being slower as the carbons increase in thickness. Carbons smaller than 9mm. for five amperes, and those larger than 40mm. for, say, 130 amperes, do not burn well, it being very difficult to obtain a well-formed crater, consequently the light is unsteady. It is the custom now in the best kind made to insert a central soft core in the positive carbon ; these are called cored carbons. They are naturally more expensive than the other solid kind, but they give a better, softer, and steadier light. The soft core tends to keep the crater in the centre of the carbon, and promotes a more regular burning ; the light also is purer and whiter. There is a great art in manufacturing electric light carbons, each maker having some little secret of his own in compounding the ingredients that form the paste. Gas-retort carbon, or gas coke, as it is called, is crushed into a fine powder and then mixed with several things, as pitch, oils, etc.; the compound is passed through a number of processes, then subjected to great pressure and finally baked in the furnace. Provided a good lamp be employed, the character of the carbon soon proves itself ; a bad and impure specimen burns irregularly, splutters, and is continually breaking its arc, and so causes the light to fluctuate up and down, and, above all, the light given off is often a greenish-red or a purple colour, making those on whom it falls have a very bilious look. A good carbon, however, acts very differently : it burns steadily, with little waste, the light is pure, full and white, and perfectly steady.

Coated or coppered carbons are those which are coated over with a thin deposit of copper, to conduct the current better. A single-carbon lamp means one that has only one pair of carbons, and a double-carbon lamp one that has two pair, so that when the first pair is burnt out, the lamp changes over on to the second pair. The usual length that carbons are cut is about 16in for positive, and 8in. for negative, so that the single lamp will burn for 16 hours and the double lamp for 32 hours. The consumption will not reach 1in. per hour for the positive, as the carbon stumps will testify ; in any case the carbons should never be allowed to burn down to less than 1in. away from the holders, otherwise the holders will get heated and burnt. The depth of holders is about $\frac{1}{2}$in., so the stumps should not be less than $1\frac{1}{2}$in. long when taken out.

(To be continued.)

THE TRAMWAYS INSTITUTE OF GREAT BRITAIN AND IRELAND.

The annual general meeting of this institute was held on Thursday of last week at the Holborn Restaurant, W.C., Mr. W. J. Carruthers-Wain occupying the chair.

On the proposal of Mr. J. EBB-SMITH, seconded by Mr A. P. SMITH, Mr. Carruthers-Wain was unanimously re-elected president for the ensuing year. The vice-presidents (Mr. J. Ebb-Smith, Mr. J. W. Turton, and Mr. A. P. Smith), on the motion of the CHAIRMAN, seconded by Mr. STANSFIELD, were re-elected. Mr. Whittaker, Mr. Waugh (of Bradford), Mr. S. J. Wild, and Mr. William Mason were elected executive committee on the proposition of Mr. S. L. TOMKINS, seconded by Mr. FORBES. Mr. FORBES then moved, and Mr. PAGE seconded, the re-election of Mr. Chris. James and Mr. W. Stansfield as honorary auditors.

The SECRETARY (Mr. J. G. B. Elliot) then read the report of the council for the year 1892-93. The report showed that there were now 32 companies, 47 delegates, and 164 associates belonging to the institute. These figures showed an increase, as compared with the previous year, of one company, 11 delegates, and four associates. One company had resigned owing to the line having been purchased by the local authority, and six associates had ceased to belong to the institute owing to death and resignation. Since the last meeting two gatherings had been held in the provinces—namely, at Birmingham in December, and at Liverpool in April. At the Birmingham meeting the members inspected the Walsall electric tramway, and the electric railway at the Liverpool assembly. The council was gratified at the success which had attended their efforts to introduce to the notice of members all the newest developments in the application of modern science to traction, and the affording to them of opportunities for viewing inventions having for their object the benefit of the tramways. The matters discussed at previous meetings included, amongst others, the consideration of permanent way construction, electric traction by overhead wires, and the amendment of the Tramways Act of 1870, claims of telephone companies and opposition to electrically-worked tramways, new car-starting and emergency brakes, and a new gas-motor car. It had been impossible to proceed with the amendment of the Tramways Act of 1870, which, by the admission of a past-President of the Board of Trade, required amending. That question concerned the convenience and comfort of 600 million passengers, to say nothing of the reasonable wishes of the large body of the investing public, whose money had supplied the facility for cheap locomotion to that enormous number of people, and whose return on their capital was in most cases extremely inadequate, whilst in many instances no return whatever could be earned by the capital employed. It was impossible for the same reason mentioned in previous years to obtain capital for tramway purposes, and new lines and desirable extensions of old lines demanded for the public convenience could not be built. The council felt that the time had come when it was the plain duty of tramway companies to bring pressure to bear on the Legislature, in the first instance by urging their shareholders to become associates of the institute, thereby greatly increasing its power and influences and resources ; and in the second place, to bring personal influence to bear upon the member for Parliament who represented the particular district in which each shareholder resided, as well as to sign a petition to Parliament praying for the appointment of a select committee to enquire into the operation of the Tramways Act, 1870, with a view to its amendment in the light of the experience gained in the past 23 years. The most important events of the year, from a traction point of view, had been the opening of the

South Staffordshire electric tramway, the Liverpool overhead electric railway, the cable tramway at Matlock, and the cable line from Kennington to Brixton. The chief event of the year had, however, been the decision of Sir Frederick Bramwell, the arbitrator appointed by the Board of Trade to decide on the price to be paid for a portion of the lines of the London Street Tramways by the London County Council. It was understood that while the price was far more than the County Council expected to pay, it was much less than satisfied the company. Any further proceedings in this case would be watched with interest. As an illustration of the justice of the views held by the Tramways Institute on the action of the local authorities and the purchase clause of the Act of 1870, it was mentioned that in the case of the London, Deptford, and Greenwich Tramways Company, who voluntarily offered to sell their lines to the London County Council at a price to be mutually agreed upon, the latter declined to entertain the suggestion.

Mr. W. J. CARRUTHERS WAIN, in moving the adoption of the report, and after referring to statistics of tramway work, spoke as follows about electric traction: "They found that whereas the application of modern science in the United Kingdom had resulted in the construction of only 33 miles of electric tramways during the 10 years since it was first commenced with the Portrush and Giant's Causeway Railway, opened in 1883, the idea of electric traction did not really take hold of the American public until 1887; and since that time the progress had been so marked, and the convenience of the additional facilities given had been so marked, that last year the number of electric tramways in the United States was 436, with 3,532 miles of track, and 5,851 cars carrying 250,000,000 passengers annually. That only showed what capital could do, what freedom from arbitrary restrictions imposed by local authorities could do, and what the study of the public convenience would result in for the shareholders in those companies. He thought if anyone had an opportunity of reading the remarks made by Mr. Reckenzaun during the discussion on Dr. Hopkinson's paper before the Institution of Civil Engineers, they would repeat the reasons why in America that could be done and not in this country. In any case, the public were the sufferers and the tramway companies the losers."

Mr. WM. MASON, in seconding the motion, observed that the institute had been of great benefit to tramways belonging to the institute, and to those who were not connected with it.

Some discussion ensued. It was mentioned that there were 80 companies in the United Kingdom, and that only 32 were affiliated to the institute; in the metropolis there was only one in seven connected with it. It was urged that the council should endeavour officially and as effectually as possible to induce those companies outstanding to join the institute. It was also suggested that the council should on the occasion of Board of Trade inspections of lines and rolling-stock, and especially steam locomotives, give some distinct advantage to the companies so as to deal with the changing requisitions of the Board of Trade, and which put the companies to considerable expense.

Mr. CARRUTHERS-WAIN said, in reply, that the council would be glad to accept the proposal, and that by so doing it would bring in other companies. The quarterly meetings would be held as usual. An invitation had been received for the institution to visit the Isle of Man in October to be present at the opening of the electric tramway from Douglas to Laxey, but he did not know whether the line would then be in operation.

A paper was down on the agenda, on "Electric Traction," by Mr. L. EPSTEIN, who, however, made his remarks in an address on

RECENT RESULTS OF ACCUMULATOR TRACTION.

When he read a paper before the institute a year ago, he then pointed out to the best of his belief that it could be proved in actual working that accumulators would fulfil all conditions necessary to make traction by their means a success. At that time certain doubts were expressed, but the author was now in a position to submit figures which he thought would prove that the hopes held out 12 months ago had been realised by the use of the Epstein cells on some of the cars of the Birmingham Central Tramways Company. There were six cars in regular operation in that town, and sometimes seven. There were 12 sets of accumulators in use. The first were supplied in December, 1892, and they had had sometimes to contend with difficult conditions of the road; several times in January and February they had to deal with falls of snow, and measurements taken disclosed the fact that the energy required to propel a car up a gradient of 1 in 25 rose to 33 i.h.p. The 12 sets, which represented 1,200 cells, or 10,000 plates, were working satisfactorily in Birmingham at the present moment, and they were the identical cells that had done work since December and during the severe conditions of the road already mentioned. As far as repairs were concerned, not a single plate had been changed or repaired; putting that into mileage, it meant that the sets in use had done about 6,000 miles, the total mileage being about 80,000. He had information to the effect that the irregularities in the traffic from any cause were very slight, and compared favourably with those on the lines operated by other means. The author then came to consider the relative merits of the accumulator system and the direct-current method. Taking first the cost of installation, he observed that it had been elicited that the cost of effectually equipping one mile of track on the overhead system amounted to about £4,000 a mile, and that of the conduit system to about £6,000 a mile. Assuming a line six miles long, that would come to £24,000 with the former and £36,000 with the latter system, apart from other electrical equipment. They knew that the equipment of a car with accumulators cost £500, apart from the other electrical equipment which was common to both. Taking a five minutes' service—which was a pretty good one—they found that on a line with double track 24 cars were necessary to maintain that service. The 24 cars would cost £12,000 as compared with £24,000 with the trolley system, and £36,000 for the conduit method. Coming to consider the cost of working, that was more economical at the station than the working of stations where provision had to be made for varying demands. The main points, however, were: What was the supervision that accumulators required, what were the repairs, and what was the cost of keeping them in working order? In other words, what was the cost of running them? On these points, he would simply record facts. As far as supervision in Birmingham was concerned, he was only aware that of the 12 sets that had been in operation since December, six sets had been cleared out once so as to get rid of the mud, and that clearing was the only expenses incurred in the supervision of accumulators; in other words, the supervision was practically nil, and also the cost of supervision. With regard to repairs, he would repeat what he had said at the commencement of his remarks—that it had not been necessary to repair a single plate out of the 10,000. As to the cost of renewals, his company was under a contract with the Birmingham Central Tramways Company to renew the accumulators, or such parts as required renewal, at a certain fixed rate per car mile run. In this case the rate was 1½d. per car mile, and each set of accumulators had made 6,000 car miles, and considerably less than that mileage was sufficient to reimburse his company for the cost of renewals.

In the course of discussion, Mr. CARRUTHERS-WAIN said that he was not an advocate of any system. He mentioned that the working of the Epstein accumulators during the past six months had enabled the lines to be operated with great regularity. With regard to the financial aspect of the question, that was not a matter with which he could deal. He only knew what the arrangements with Mr. Epstein were or were likely to be, and he would wait until the end of the year, which terminated on the following day, and then find out what the cost of accumulator traction had been on the Birmingham line during the past 12 months. The figures given by Mr. Epstein had been supplied by the tramway company.

Mr. FELL asked as to the cost of equipping a tramway, including the rolling-stock, motors, batteries, and plant at the depôt, but leaving out of consideration the depôt and

the tram line. The tramways had the lines, and it was most important to tramway men to know the cost of installation.

Mr. SCOTT RUSSELL said that the Brush Company would undertake the responsibility for the equipment of a line, and they had calculated that to extinguish the extra capital outlay involved in the fitting up of an existing line with electric traction, a sinking fund of 1½d. per car mile was necessary. That was one of the serious considerations they had had to deal with in this country—that the existing horses and cars had to be put aside, and before any saving could be shown a saving must be manifested over and above a sinking fund of 1½d. per car mile. Unless it could be demonstrated that something like 2d. was to be saved, it was scarcely worth while to equip a line electrically, except for one consideration. All mechanical powers allowed of traffic being dealt with as it arose; with mechanical power a much larger car could be run at practically the same cost per car mile.

Mr. EPSTEIN had worked out on a different basis to that of the previous speaker, but in order to show the actual amount, no matter how it was to be refunded, he found that it was as near as possible £1,000 per car.

Mr. FELL asked for an approximate estimate of equipping, say, 10, 20, 50, or 100 cars. That would bring in all tramway companies now experiencing any difficulties.

Mr. EPSTEIN replied that it would be about £1,000 per car, and he stated that he would undertake to maintain accumulators at 1d. per car mile.

A paper was then read by Mr. CONRADI, C.E., on the "Cleaning of Permanent Way."

The next paper, presented by Mr. H. U. WOLLASTON, dealt with the

LIGHTING OF OMNIBUSES AND TRAMCARS.

The author described the system of compressed oil-gas lighting introduced by Messrs. Pope and Son, Limited, of Slough, on railways, tramways, and for omnibuses. The arrangement consists in the carrying on the cars of gas-cylinders, which are charged with gas from stationary high-pressure holders. The cost is given at 15s. per thousand for the gas placed on the cars, being one-tenth of a penny per lamp per hour.

The next paper, of which we give an abstract, was by Mr. E. FREUND on

LIGHTING OMNIBUSES BY ELECTRICITY.

The apparatus consists of a Bristöl battery weighing about 8lb., and a lamp of very shallow design, which can be fixed with three screws to the roof of the 'bus. The battery contains six cells, connected for power—viz., for 12 volts. The cells are made of ebonite, which is the only material which permanently resists the sharp tooth of sulphuric acid, and which is at the same time the best insulating material known. Each cell contains a positive and a negative electrode, well distanced from each other, and submerged in diluted sulphuric acid. The positive plates consist mainly of peroxide of lead, the negative plates of spongy metallic lead, and both contain a thin strip of lead, which projects out of the plate, and which serve to make the connections. These plates are manufactured by the Bristol Electric Safety Lamp Works under Bristol patents, and differ greatly from all other plates by having no metallic frames. Such frames do not take part in the electro-chemical process of storing and discharging electricity, and as they very often weigh more than the active material, their absence means a great gain in point of weight.

Being quite homogeneous, the Bristöl plates are less affected by change of temperature or shock than any other plates, and they will permanently stand high rates of charging and discharging. Looking at this from the point of view of omnibus-lighting, where, say, a five-candle lamp is wanted for six hours on an average, a Bristol A A battery, weighing 8lb., can discharge fast enough to maintain this light, while 15lb. or 20lb. would have to be carried were another type of battery chosen. Compactness and small weight are not only convenient, but they influence the price of maintenance very favourably. If several hundred batteries have to be handled in the shortest possible time, 10lb. extra apiece will tell on the wages' bill. Being bulkier, heavy batteries will require more space on the charging tables, the charging office will have to be larger, and more attendants will be required for replenishing the liquid as well as on account of the larger table space. The same increase will take place with all expenses connected with the collecting and repairing of the batteries.

The ebonite cells are closed with a splash and acid proof cover, which contains a small hole in the middle through which the harmless gases which develop principally during the charging may escape. The metal terminals of the plates pass through these covers, and are joined above in the proper way and connected to the battery terminals. These consist of flat strips of brass fixed to the front of a wooden box, into which the ebonite cells are cemented. They are about 1½in. apart from each other, and correspond with a pair of strong metal springs, which are fixed to the inside of a case provided under the seat of the omnibus. Two well insulated wires connect the contact springs of the case with the electric lamp. They are carried up behind the upholstering, along the pillars and principals of the roof, and are hardly noticeable and quite out of the way.

The lamp, which is another remarkable feature of the Bristöl system, consists of a wooden base of 5in. diameter, which carries a metal frame and a screwed bezel for the hollow crystal lense. The incandescent lamps are of Ediswan's fairy type, and are supported by elastic hooks of hard-drawn wire which cushion the constant vibrations effectively, and cause the light to be perfectly steady. From the experience gained with this method it can be said that incandescent lamps last under these conditions from three to four months. . . .

The charging takes between three and seven hours, according to the duration of the lighting, and, except the replenishing of the diluted acid, which a boy does every fortnight, no other electrical work is wanted. The expense for current is a very small item as long as the batteries are regularly used and returned. Repairs also do not amount to much so far as electrical wear and tear is concerned. The only difficulties encountered were caused by guards which short-circuited the batteries by putting them face to face, and partly by carelessness in returning the batteries without even strapping them. The first-named stumbling block was removed by putting protectors on to the batteries which make their terminals inaccessible so far as accidents are concerned. The second difficulty can easily be overcome by the use of boxes for the collection of the batteries.

An estimate for lighting 200 omnibuses could, for the first year, be made up in the following way:

Outfit, £3. 10s. per 'bus	£700	0	0
Twenty spare batteries at £2. 10s. each	50	0	0
Fitting up of charging station	25	0	0
First cost	£775	0	0
Electric current per annum	£50	0	0
Wages	150	0	0
650 incandescent lamps at 1s. 6d. each	48	15	0
Repairs	£50 to 100	0	0
Rent for charging station	10	0	0
Depreciation, 15 per cent.	116	5	0
Maintenance	£475	0	0

or £2. 7s. 6d. per 'bus per year, as a maximum for the first year.

Nothing is allowed in this estimate for careless or malicious treatment, or for management. These items depend greatly on circumstances, which have to be considered in every case. The item for repairs, however, include an ample allowance for accidents on the road and mistakes of the attendant.

The Secretary then read a paper by Mr. SHARP, on "The Connelly Motor."

The last paper read was by Mr. J. M. GROB, on "A New Petroleum-Motor."

Aberdeen.—The sanction of the Secretary for Scotland has been received to the loan of £20,000, to be raised by the Aberdeen Town Council for the erection of the works for the electric lighting.

Vol. X. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s*

GAS POWER.

This is the title of a paper by Mr. J. Emerson Dowson, read at the late meeting of the Gas Institute. Mr. Dowson, as all men know, is the great advocate of the gas-engine and ——. There is much in this and ——. But, advocate of the gas-engine as he is, we claim him to be also one of the best advocates of electric lighting. Mr. Dowson assumes the correctness of the statements made by Dr. Hopkinson, the late Dr. Siemens, and Mr. Gisbert Kapp, to the effect that "when ordinary town gas is burnt in a gas-engine to drive a dynamo, much more light is produced electrically than can be produced by burning the same quantity of gas in burners in the usual way." We have heard this statement denied by those who ought to know better. They argue that it cannot be, because of losses in engine, dynamo, and mains. They forget, or they do not know, that consuming ordinary town gas for light purposes is not the same as consuming it for heat purposes. On a blustering Saturday or any other night the flaring gas jets in the shop windows are almost blown out, so to speak, as far as light is concerned, but the heat generated by the jets is far greater than under ordinary conditions. A Bunsen burner consumes the gas to give heat, but not much light. Therefore, it is somewhat easy to see that by consuming the gas for heat in an engine may be far more economical, even after allowing for all losses, than burning it for light. Mr. Dowson, as we say, admits the correctness of this view, but goes further, and says that while it is economical to use town gas for burning in engines, it is still more economical to use gas prepared specially to be consumed for heating and not for lighting. For some years he has held forth on this thesis—the electric light is better than gas light; it is bound in the long run to take first place; its production requires the use of prime motors—then why not, you who have investments in gasworks, gird up your loins, take the bull by the horns, provide cheap gas for engines, then utilise your works, and provide what the public most assuredly will require.

Mr. Dowson, in the paper above referred to, was trying to convince gas engineers, and believing that facts are the stubbornest of all arguments, he adduced the results obtained at Dessau, saying: "I visited Dessau last autumn, and it is through the courtesy of the managing director (Herr W. von Oechelhauser) that I am able to give you the above results. In this country it is usual to allow 60 watts per hour for a 16-c.p. lamp; but on the Continent it is more common to allow only three watts per candle-power, or 48 watts per 16-c.p. lamp. At Dessau the actual consumption is under this. If, however, we take the English allowance of 60 watts to give the light of 16 candles, and if 41 cubic feet of gas are consumed to produce 1,000 watts as at Dessau, one of these lights will require under 2½ cubic feet per hour; whereas a standard argand burner requires five cubic feet, and an ordinary flat-flame burner considerably more. We see, therefore, that in actual working there is a saving of 50 per cent. in favour of burning

the gas in the engine, and in producing the light electrically in incandescent lamps."

The Dessau results referred to in this quotation were that, taken over an average of thirty days in December last, the consumption of gas was 40·82 cubic feet per kilowatt-hour generated at the terminals of the dynamos. This is a fact which, unless it can be shown to be erroneous, speaks volumes as to the value of burning gas in an engine in order to produce electric light. We are extremely surprised at the recent policy of gas-engine builders. They seem to imagine that electric light is played out, and put little or no energy into pushing business in this direction. But Mr. Dowson tells them that "electric lighting is no mere fad—it has come to stay and to grow; and although gas engineers would rather be without it, they know well enough that the world will go ahead and have what it believes to be best and what it prefers." The tendency of some of the best electrical engineers is to give gas-engines a more extended trial than hitherto, and to instal them for central-station work. There is no doubt about the accumulated proof of their value for isolated installations. We might suggest to the authorities at Nelson, one of the most go-ahead towns in Lancashire, that when additions are required to their electric lighting plant, as additions will be required, they have every opportunity of giving a thorough trial to gas-engines. They are the owners of the gasworks and the owners of the electric lighting works. Both works are, so to speak, in a ring fence—under the same management; and under these conditions admirably suited for giving Mr. Dowson's suggestions an exhaustive trial.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ACCUMULATOR TRACTION.

SIR,—Replying to Mr. Broekman's letter in your last week's issue, I would like to suggest that the question of the advantages of the accumulator system over any other form of traction is not to be proved by the bald statement, that the Epstein Accumulator Company have entered into an agreement with the Birmingham Central Tramways Company to maintain their cells at 1½d. per car mile.

The superiority of accumulators over any form of traction is best proved by the balance sheet of a tramway company using that system, and I look forward with much interest to the publication of the Birmingham Central Company's balance-sheet, shortly to be issued, to see how far that document agrees with the evidence given by Mr. Epstein before the Joint Committee of the Electric Power Protection Clauses as regards the economy of the accumulator system, and also with Mr. Broekman's statement that the working of the Bristol road section of the Birmingham Central Tramways is cheaper than other direct system, and more regular and reliable in working than any other section of that system of tramways.—Yours, etc.,

STEPHEN SELLON.

35, Parliament-street, S.W., July 4, 1893.

Magnet Armatures.—To overcome the residual magnetic effect in electromagnets, Mr. S. H. Stupakoff makes his magnets with a thin sheet of soft iron in between the poles and the armature. This is found sufficient to neutralise the effect of residual magnetism without perceptibly increasing the magnetic resistance.

POLARISATION OF PLATINUM ELECTRODES IN SULPHURIC ACID.*

BY JAMES B. HENDERSON, B.SC.

This investigation was begun about the beginning of February, 1893, at the instigation of Lord Kelvin, and was conducted in the physical laboratory of Glasgow University. The object of the investigation was to obtain the difference of potential between two platinum electrodes immersed in a solution of sulphuric acid immediately after the stoppage of a current which had been electrolysing the solution, and to find how this difference varied with a variation in the intensity of the current or in the strength of the solution.

Former experiments by Buff (*Poggendorff*, vol. 130, p. 341, 1867) and Fromme (*Wiedemann*, vol. 33, p. 80, 1888) have given for the maximum polarisation with platinum wires of very small surface in the electrolysis of dilute sulphuric acid 3·5 and 4·6 volts.

Dr. Franz Richarz, in a paper "On the Polarisation of Small Electrodes in Dilute Sulphuric Acid," read before the British Association at Bath (1888), says of the above: "In these experiments the polarisation is calculated from measurements of the intensity of the galvanic current during the electrolysis, tacitly assuming that the resistance of the decomposition cell is independent of the intensity of the galvanic current. The correctness of the supposition has not been proved. I tried experiments by similar methods, and obtained yet greater values of the polarisation; it was calculated with a current density of 12 amperes per square centimetre as 4·4 daniells (4·7 volts), and increased more and more with increasing intensity of the galvanic current. It is very improbable that this can be right. By supposing, however, that the resistance of the decomposition cell is not independent of the intensity, but decreases in a fixed manner with increasing intensity, the calculation of the same experiments gives small and constant values of polarisation."

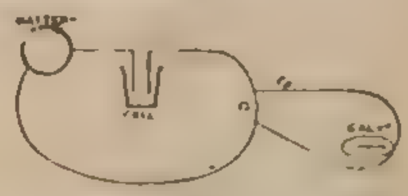

FIG. 1.

The method Dr. Richarz used to find the polarisation in his investigation was independent of the resistance of the electrolytic cell. The battery electrolytic cell and a switch, c_1, were joined in closed circuit. A branch circuit containing a very high resistance, a galvanometer, and another switch, c_2, joined the two sides of the switch c_1 (c_1 and c_2 were the two contacts of a Helmholtz's pendulum interrupter). When c_1 was made there was a very small current through the galvanometer. To determine the polarisation, c_1 was broken, and immediately after c_2 also. In the short time between the interruption of c_1 and c_2 a current strong for the sensibility of the galvanometer went through it. The polarisation was calculated from the deflection given to the galvanometer needle by the impact of the current, which was proportional to the E.M.F. of the battery, minus the polarisation. In this way Dr. Richarz found values for the polarisation never greater than 2·6 volts with small wire electrodes, and also got the same maximum with large platinum plates.

The cell used in the present investigation was a cylindrical glass vessel 10cm. diameter and 12cm. deep. The electrodes were rectangular plates of platinum foil 7cm. long by 5·5cm. broad, and were stiffened by being mounted on rectangular frames made by bending glass tubing, Fig. 2. The tubing of these frames also served to support the plates in vertical planes by being passed through holes in a bar of wood placed across the mouth of the vessel. The plates were immersed in the solution to a depth of 5cm., having their planes parallel and about 1cm.

* Paper read before the Royal Society. Communicated by Lord Kelvin, F.R.S.

apart. There were thus 55 square centimetres of surface of each plate wetted. To find the polarisation one of Lord Kelvin's quadrant electrometers was used, and by an arrangement, described later, the breaking of the electrolysing current circuit and the switching of the electrodes on to the terminals of the electrometer were done simultaneously. Before switching as above, however, the needle of the electrometer was deflected by making a difference of potential between the pairs of quadrants, and this deflection was so adjusted by trial and error that, when the electrodes were switched on, the needle was no farther deflected. For deflecting the needle of the electrometer a high resistance slide bridge was used. A difference of potential was maintained between its two ends, and the difference of potential between one end and the slider was used to deflect the needle, so that by moving the slider one way or the other the deflection could be increased or diminished at will. The electrolysing current was kept constant throughout each experiment, being measured by one of Lord Kelvin's electric balances and adjusted by a rheostat. One terminal of the electrometer, one electrode, and one end of the slide bridge were connected together and then put to earth. The current for the electrolysis was got from eight large secondary cells, and the difference of potential between the ends of the slide bridge was maintained by two small secondary cells. The arrangement of keys can be best understood from the diagram. By pressing the key k', connection was made between the slider and the unearthed quadrants, and when the key k was free the circuit was complete for the electrolysing current, but when k was pressed down the circuit was broken, and the unearthed electrode was connected to the unearthed quadrants.

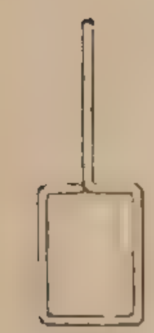

Fig. 2.

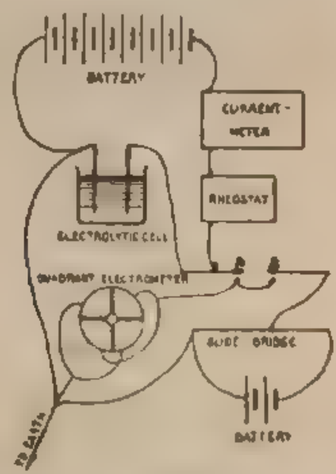

Fig. 3.

The order of an experiment was the following: After standardising the electrometer by means of a Clark cell the electrolysis was started, and the unearthed electrode connected by a wire (not shown in the diagram) to the unearthed quadrants. The deflection of the needle thus produced, which showed the difference of potential between the electrodes, continued to increase steadily until, after the lapse of an interval of time depending on the strength of the current, it became constant. When this stage was reached the wire mentioned above was removed and the key k' pressed and kept down, thus making connection between the slider and the quadrants. The slider was then moved along until the deflection was nearly equal to that which would be given by the polarisation, and the key k momentarily pressed, thereby breaking the current circuit and connecting the electrode to the quadrants. An impulsive deflection immediately followed, unless the potential of the quadrants was equal to that of polarisation. If this deflection was negative (which indicated that the potential of polarisation was less than that of the quadrants) the slider was moved so as to reduce the potential of the quadrants below that of polarisation, thereby making the impulsive deflection positive, and then the experiment was continued as below. When the positive deflection was obtained its amount was noted, and the slider was moved so as to *increase* the steady deflection nearly up to the point on the scale reached by the impulsive one, and another trial then made. In this way, by watching the point reached by each impulsive deflection, and then increasing the steady one almost up to that point, the latter was increased until the former vanished—that is, until the potential of the quadrants was that of polarisation. The magnitude of this deflection was then noted, and the polarisation calculated from it. In these trials the key k was kept down only for about two seconds, just sufficient time to allow the extent of the deflection to be seen, and at least two minutes were allowed to elapse between one trial and the next. After the maximum deflection had been reached, a considerable interval of time was allowed to elapse, and then the key k' raised and k simultaneously lowered and kept down, and the rate of fall of the deflection noted. The above motion of the keys threw the slider off and put the electrode on to the quadrants, at the same time stopping the current. The deflection was therefore due to polarisation alone, and its rate of fall was therefore the rate of fall of the polarisation.

The results of one series of experiments are given in the accompanying table. All the results point to the polarisation being constant with large electrodes, being independent of the strength of the solution and the intensity of the current. The variations in the figures do not occur in any order, and are all such as might be expected in experimental results of this nature. Some of the greatest variations were obtained in exactly similar experiments performed at different times. The mean of all the values of the polarisation in this table is 2·09 volts. The rate of fall of the polarisation depends on the time the current has been electrolysing the solution, and also on its intensity, but in every case the fall is very rapid at first, being in some cases as much in the first minute as it is in the next five minutes, and the fall in the first minute is never less than one-fourth of the polarisation.

Percentage strength of solution.	Strength of current in amperes.	Deflection for Clark cell.	Deflection for polarisation.	Time the current had been passing.	Polarisation in volts.

Mean polarisation = 2·09 volts.

THE ACTION OF COMPOUND DYNAMOS WHEN RUN IN PARALLEL.*

BY WILLIAM L. PUFFER, S.B.

While arranging some details of the wiring plan for connecting up two compounded railroad generators so that they could be tested for commercial efficiency while under the conditions of full load by one of the purely electrical methods, my attention was drawn to the fact that the usual method of adjusting such dynamos so that they would give a constant potential at their terminals, irrespective of the current flowing, could not be a correct one unless the machines were exactly alike in all respects.

The general practice is to over-compound such generators, and then to experimentally shunt the series coil with a German-silver ribbon until the desired "0 per cent. rise" is obtained; this is well enough for a single dynamo, but when two or more are in parallel, with their series coils also in parallel, the German-silver shunts do not in any

* From *Technology Quarterly*, vol. v., No. 4, December, 1892.

way aid the different dynamos in equalising their load, and any original structural difference will cause the load to divide unequally. I found that in all the power plants that I could then visit (winter of 1890 91) there was very decided evidence of this tendency to unequal division of the load, and it could readily be seen that some machines were always taking more than their share of an increase of load and tending to do too little when the load fell off. There seemed to be a very common knowledge of the trouble in making the dynamos work well together, but there seemed to be no attempt to help the matter, or, as far as I could find, any knowledge of where the fault was.

A year ago the Thomson-Houston Electric Company was so kind as to loan the institute a pair of similar over-compounded motor-type dynamos which had been adjusted for "0 per cent. rise"; these dynamos were similar to the power generators of that company, and enabled me to make a study of the action of compound generators connected in parallel. The dynamos were belt-driven from the main shaft in the dynamo-room of the physical department, and were under good average running conditions. A short piece of shafting was arranged so that by slipping the pulleys slightly the two armature shafts could be mechanically connected, and therefore must at all times be at the same speed. Suitable water resistances connected to each machine were used for varying the output of the armatures. Double pole jack-knife switches of the type generally used were provided for connecting the two dynamos in parallel.

and connections up to the distribution point or 'bus bar where the voltmeter was connected (curve 5). These separate losses may be plotted separately, and their sum will equal the amount that the net characteristic will fall below a horizontal line.

Inasmuch as the net characteristic in this combination is a very drooping one, it would be necessary to use hand or automatic means of adjusting the voltage as the current changes, so as to keep the mains at the normal value—the effect of this regulation can be considered to be a raising or lowering of the net characteristic bodily without any material change in the inclination. Such regulation is always too late by at least the time necessary to produce a change of the indicating device, yet if this amount is small and the demand for current is not very variable, such a combination is perfectly satisfactory, and even desirable, on account of the sudden fall of voltage on a short circuit, which lessens very materially the shock to all parts of the system.

A second similar combination can be connected in parallel to this first one, and the load divided between them—all that is necessary is to have the voltage of the incoming system very nearly equal to that of the 'bus bar or common point, and then to close the switches. Evidently, if the voltage of the new dynamo were just right, no current could pass in either way, but if it were somewhat too high then a part of the total current would change from the old dynamo to the new one. If, for example, the new dynamo

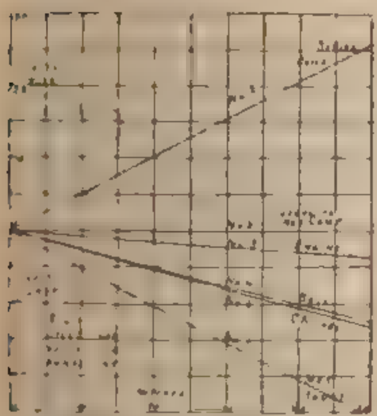

Fig. 1.

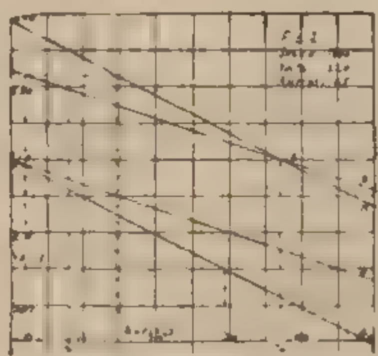

Fig. 2.

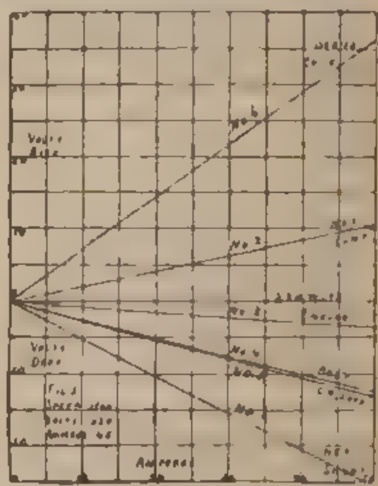

Fig. 3.

A dead-beat ammeter was placed in each armature circuit, and an Ayrton and Perry spring ammeter in the equalising wire. A Weston voltmeter was used in connection with pressure wires to measure the voltage of either armature.

The object of this paper is not to describe these tests, but rather to explain a method of investigating the action of compound dynamos in parallel, and to point out the cause of some of the difficulties commonly met with, as well as to show that it is comparatively a simple matter to avoid them; so that the results of these tests, although very interesting, will not be given except as explanatory examples.

Considering first the action of a single-shunt dynamo driven by a belt from an engine doing no other work, if now the load be gradually increased to the maximum amount that can be safely carried, and if from time to time simultaneous values of the current and voltage be taken and plotted as in Fig. 1, curve 1—for want of a better name let us call this the net characteristic curve of the combination—this curve would be a horizontal line (curve 2) if it were not for the sum of a number of actions, all of which tend to lower the E.M.F.; beginning at the engine there is the usual fall of speed as the load increases, due simply to the action of the governor (curve 3), the dynamo pulley lags behind more and more on account of the increasing slip of the belt as the transmitted power becomes greater, these two changes are plotted in curve 4; in the dynamo armature there are the usual demagnetising reactions which lower the E.M.F.; and finally, there is the fall of potential in the armature wires as well as all the necessary leads, fuses, ammeters,

were x volts higher than the old, then the current through it would be of such value as would cause a fall of $\frac{1}{2}x$ on the net characteristic, and the current from the old dynamo would be smaller by the same amount. When the net characteristic is quite drooping, as is always the case with shunt dynamos, there is little or no danger of even overloading an armature when connecting it to the mains—in fact, it is common practice in central stations to judge of the voltage of the new dynamo by the looks of its pilot lamp. If the two units (dynamo with its engine) have similar net characteristics, any change of load, sudden or not, will divide equally between them; but if, as usual, the characteristics are not similar this will not be the case, and we shall find that the unit with the steepest characteristic will not take its share of the work if the load increases, and will take more than its share with a decrease of load.

Let the lines A and B in Fig. 2 represent the net characteristics of the two units; when the armatures are in parallel and delivering no current, let the voltage be brought to 220 volts, then the two lines are common, as at a. A sudden current of 74 amperes will cause the voltage to drop to 205, and B will deliver 45, and A 29 amperes. If now the load is equalised with 37 amperes in each armature, and the voltage brought up to 220 by the use of the regulating rheostats, the lines A and B are raised to A^1 and B^1 respectively, being common at b; now let the total current be diminished from 74 amperes to 16·5 amperes, a similar construction shows that the voltage will rise to 231·6 volts, and that A will deliver 14·5 amperes, and B two amperes.

When two dynamos with net characteristics like these are subject to a rapidly-changing load, it is impossible to evenly divide the current, and a balance has to be struck between the limits, on the one hand, of the dynamo, A, driving B as a motor—which will, of course, do no especial harm other than to waste energy in heating and sparking—and, on the other hand, of melting the fuses of dynamo B during an unusually heavy call for power, which might have been safely carried by the fuses if equally divided. It is plain that in this case the combination of the two dynamos is not double the capacity of either one, and the commercial efficiency is considerably lessened by the want of similarity of the net characteristics.

It is very desirable on many accounts to have a dynamo which will automatically maintain an approximately constant potential at the switchboard irrespective of the amount of current flowing. We may add a series winding to the dynamo of just sufficient number of turns to give such a magnetising effect as will produce a voltage which shall be at all times exactly equal and opposite to the combined effects of the change in engine speed, belt slip, armature reactions, and the drop of voltage due to the resistance of the armatures, lead wires, ammeter, safety devices, and the like, up to the 'bus bar (Fig. 1, curve 6). The net characteristics will now be made up of the sum of the individual effects, as shown in Fig. 1, curve 2, and the voltage at the switchboard would be constant at all times were it not for the hysteresis of the iron in the magnets, which will very slightly prevent the instantaneous rising and falling of the effect of the series coils, and any change in resistance due to temperature change. The temperature change will be slow, and is corrected by an occasional change of the rheostat in the shunt-coil circuit, and can be neglected for the present.

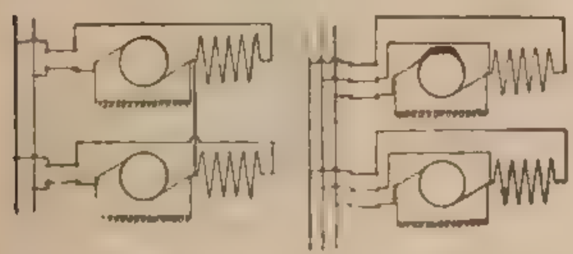

Fig. 4. Fig. 5.

Should it be necessary to use a second dynamo of exactly similar design, we cannot proceed as in the case of simple shunt dynamos, for this reason: If the new dynamo is at exactly the same voltage as the mains at the switchboard when connected in parallel, the combination will be unstable, because if for any cause the voltage of either dynamo varies a little, so that the new machine becomes ever so slightly a motor, the effect of the reverse current in its series coil will be to weaken still more the E.M.F., which will allow an increasing current to flow until something burns out.

If, however, there is a third connection made so that the brushes as well as the terminals of the two dynamos are connected, it becomes impossible for this reversal to happen, and the machines will run perfectly under all changes of load. There are in use two ways of arranging the switches, Figs. 4 and 5, either of which is satisfactory; but the one shown in Fig. 5 is better, as the idle machine is completely disconnected from the circuits.

An examination of the components of the net characteristics, Fig. 1, curve 2, shows us that if the incoming dynamo be brought up to the voltage of the switchboard, and the switch closed, the load will instantly divide between the two dynamos with no disturbance or shock of any kind. Suppose, for instance, that the loaded machine is giving out 40 amperes, we see from the net shunt characteristic, Fig. 1, curve 1, that there is a drop of 20·5 volts, which is made up by the effect of the series coil, curve 6, giving a terminal potential of 220 volts. When the new machine at 220 volts is switched in parallel, we may first consider that one half the total current of 40 amperes passes through each of the parallel series coils, and from curve 6 we see that the volts rise is cut down from 20·5 to 10·2 in the first dynamo and raised from zero to 10·2 in the new one; from curve 1 we see that for each dynamo this change of 10·2 volts just compensates for a current of 20 amperes through the armature circuits, and that the total load of 40 amperes at 220 volts will be equally divided between the dynamos.

The action of compound constant-potential dynamos in parallel is generally misunderstood, and the equalising connection is credited with a remarkable power of control over the output of such dynamos which it does not and cannot have, as can be seen by watching the dynamos while at work as well as by examination of the make-up of the net characteristic, Fig. 1. The common idea is that the equaliser has the property of compelling a lagging dynamo to take its share of the work, and we hear of the wonderful power of control which it has even over dynamos of different types and sizes running under somewhat different conditions. Now the real effect of the equaliser is to put the series coils in parallel, so that the total flow of current from the plant will divide between them inversely as their resistance without any regard as to whether this current comes from one armature alone or is divided among many, and hence it follows that it cannot in any way exercise even the slightest regulating effect on any one dynamo that it does not have over all the rest. The armatures themselves are running in parallel under the usual conditions of ordinary shunt dynamos, and the total current will divide between them under the same laws that would hold if there were no series coils at all and the current were taken from the two main wires to which the brushes are connected, as has been already pointed out in a previous part of this article.

The net characteristic of the plant is then a falling one, as far as the armatures are concerned, to which has been added the automatic regulation of the parallel series coils which act together in proportion to the total flow of current from the station; and if these series coils are all alike in effect, each dynamo will have its voltage altered by an equal amount in proportion to the output of the station, but each armature will not do its share of the work unless all the net falling characteristics are exactly similar.

In a plant of such dynamos, each driven by its own engine, it is most likely that the net falling characteristics of the armatures will not all have the same steepness, and consequently a fluctuating load will not be shared equally by the dynamos; but it is possible to so arrange things that the series coils do not all act equally on the armatures, and if the resistances of the series coils are slightly changed by the addition of a little German-silver or copper ribbon, so that the total flow of current divides between the different series coils in such a proportion that the individual net armature characteristics are raised by just the right amount, we again have a plant in which a fluctuating load will divide equally among the different dynamos. The same effect may be produced by the addition of a small resistance in the armature circuit of any dynamo which takes more than its share of an increase of load. A number of machines so adjusted will run together perfectly, and there will be no change of voltage or any difficulty experienced in cutting in or out by the use of the ordinary two or three pole switch; the only precaution to be observed is to have the voltage of a new machine nearly that of the 'bus bars, for then, when the series coil is put in parallel with all other series coils, it will be traversed by such a part of the total flow of current as will be sufficient to raise the voltage of the armature enough to enable it to deliver its share of the total output.

If a dynamo is to be cut out it will not do to reduce its load first by the use of the resistance in the field circuit, because by this process its load is transferred to the other dynamo armatures and the station voltage will consequently fall somewhat, because the series coils are not proportionately increased. This fall of voltage may or may not be permissible, and is avoided if the switch is opened while the dynamo has its share of the load.

Sometimes it is desirable to have a dynamo which will maintain a constant potential at a point some distance from the switchboard; in this case the series coils will have a few more turns, so as to make up for the fall of potential in the mains; and in Fig. 3 will be found the component curves

for a dynamo adjusted for approximately "5 per cent. rise." Curve 1 may be called the "net shunt" falling characteristic made up of the sum of the effects due to the engine change, belt slip, and the fall of potential in the armature circuits represented respectively by the curves 3, 4, and 5. Curve 6 shows the rise of voltage due to the current in the series coils, and is greater than the total drop, curve 1, by an amount plotted as curve 2, which is the net characteristic of the over-compounded dynamo.

Should the demand for current exceed the capacity of one dynamo, the addition of a duplicate machine will render it impossible to maintain a constant potential at the distant centre unless both dynamos are run all the time; for while 45 amperes on one dynamo will cause a net rise at the switchboard of 9·5 volts, the same total current furnished by the pair will only produce a rise of 4·75 volts.

If this want of exact regulation does not require the constant running of two dynamos at times of light load, we meet greater troubles in the process of adding the second unit when the load is too heavy for the first one. From the data given in Fig. 3 it is possible to see what will happen under any given conditions when the machines are put in parallel. I have experimentally verified this method of predicting the actions of compound dynamos, and find it exact enough for all practical purposes.

Suppose one dynamo is loaded, what will be the effect if we connect a new one when its voltage is lower, the same as or higher than the switchboard? I will take from my note-book the results of some experiments on two dynamos with characteristic curves like Fig. 3, first giving the observed results, and then calculating them from the curves.

The armatures were mechanically coupled, and therefore at the same speed. Voltage of each was 222; 30 amperes were taken from No. 2 dynamo, and voltage rose to 228, while that of No. 1 fell to 212; then by a double-pole switch No. 1 was put in parallel. Momentarily No. 2 tended to overload and drive No. 1 as a motor, but in a few seconds the load became steady at a voltage of 222, No. 1 furnishing 18 and No. 2 12 amperes. Now by calculation from curves of Fig. 3:

No. 1.	No. 2.	
222	222	Volts at switchboard with no load.
- 7·5	- 7·5	Curve 4. Drop due to speed change when a current of 30 amperes was taken from No. 2.
214·5	214 5	
	- 8	Curve 5. Armature drop with 30 amperes.
	206 5	
	+ 21 5	Curve 6. Rise from 30 amperes in series coils.
	228·0	Switchboard voltage with 30 amperes output.

Put in parallel with same load, so no change is to be made for speed change. From curve 6 we see that the change of half of the current from the series coil of No. 2 to No. 1 will raise No. 1.

No. 1.	No. 2.	
214·5	228·0	No. 1 with no load and 30 amperes on No. 2, and then put in parallel.
+ 12·0	- 12·0	Curve 6. Change in voltage with change of half current from series coils of No. 2 to series coils of No. 1.
226·5	216·0	
- 4·	+ 4·	Curve 5 Suppose each armature carried one half the current, then there would be a drop in No. 1 and a rise in No. 2.
222·5	220·0	

We must now add a current to the highest voltage dynamo, or No. 1, that will cause a drop of one-half of 222 5—220 volts, which from curve 5 will be 4·7 amperes.

Then the voltage of the combination will be 221·2; and dynamo 1 will deliver 15 + 4·7 = 19·7 amperes, and dynamo 2, 15 - 4 7 = 10 3 amperes.

Calculated 19·7 amperes, dynamo 1. 10·3 amperes, dynamo 2. Voltage of 221·2.
Measured 18 amperes, dynamo 1. 12 amperes, dynamo 2. Voltage of 222.

Take, for another example, the case when one of these dynamos was at full load, and the new machine was brought up to exact voltage and then put in parallel, and applying these methods we shall see that it may happen that all current may be cut off by the melting of a fuse.

Dynamo No. 1 at 220 volts and no load, then as the load of 45 amperes comes on, the switchboard voltage will be about 230 volts.

220	
- 11·2	Drop due to load. Curve 4.
208 8	
- 11·7	Drop in armature. Curve 5.
197 1	
+ 32 5	Rise from series coil. Curve 6.
229 6	Volts at switchboard.

Here the switch is closed.

No. 1		No. 2	
229 6		229·6	
- 16·2	22½ amperes in series coil. Curve 6	+ 16 2	
213·4		245·8	Armature voltage.
+ 11 7	Curve 5, to find internal voltage.		
225·1	Armature voltage.		

245 8	Armature voltage No. 2.
225 1	Armature voltage No. 1.
20 7	Difference of armature voltages.
11·7	Drop in No. 2 with 45 amperes.
2) 9·0	Acting to send reverse current through No. 1.
4·5	Curve 5 corresponds to current of about 17 amperes.
245·8	Armature voltage No. 2.
- 17·0	Drop with 62 amperes. Curve 5.
228·8	Switchboard voltage.

Dynamo No. 1, which was loaded, has a reverse current of 17 amperes, and is driven as a motor, while the new dynamo carries the load and is 17 amperes beyond its rated capacity. We see that the switchboard voltage practically does not change under these conditions, but to offset this there is the sudden change of a loaded dynamo into a partially loaded motor and an overload on the incoming dynamo. Such changes would be accompanied by much sparking at the brushes and the liability of thrown belts or blown fuses. Then we may say that if the new dynamo is of lower voltage when connected the voltage will change considerably, but there will be no shock to the dynamos; if the new dynamo is at the same voltage then the voltage will remain about constant and the armatures will receive a shock; if the new machine is still higher, then the shock will be very severe and the voltage will rise. I had no time for taking readings on the last experiment, but I did notice that the needle of a 150-ampere instrument was out of sight before a switch could be opened.

(To be continued.)

ON LIGHT AND OTHER HIGH-FREQUENCY PHENOMENA.*

BY NIKOLA TESLA.

(Continued from page 650, Vol XI.)

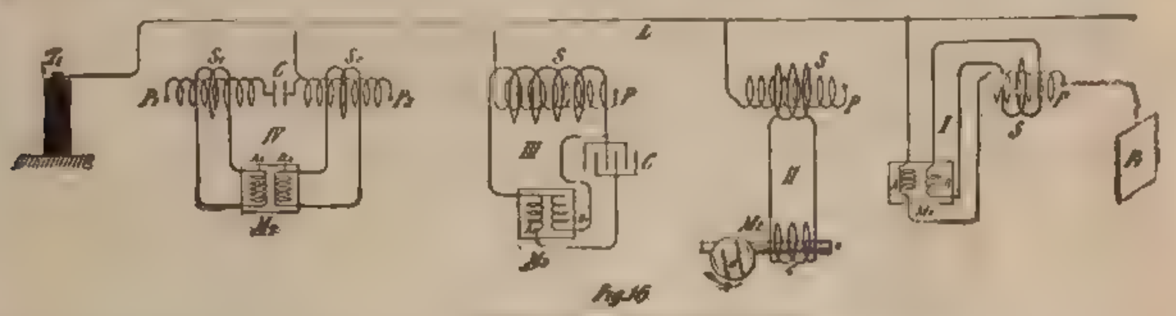
The preceding experiments will have prepared one for the next following results of interest obtained in the course of these investigations. Since I can pass a current through an insulated wire merely by connecting one of its ends to the source of electrical energy, since I can induce by it another current, magnetise an iron core, and, in short, perform all operations as though a return circuit were used, clearly I can also drive a motor by the aid of only one wire. On a former occasion I have described a simple form of motor comprising a single exciting coil, an iron core and disc. Fig. 16 illustrates a modified way of operating such an alternate-current motor by currents induced in a transformer connected to one lead, and several other arrangements of circuits for operating a certain class of alternate motors founded on the action of currents of differing phase. In view of the present state of the art it is thought sufficient to describe these arrangements in a few words only. In the diagram, Fig 16 II., shows a primary coil, P, connected with one of its ends to the line, L, leading from a high-tension transformer terminal, T_1. In inductive relation to this primary, P, is a secondary, S, of coarse wire, in the circuit of which is a coil, *c*. The currents induced in the secondary energise the iron core, *i*, which is preferably, but not necessarily, subdivided, and set the metal disc, *d*, in rotation. Such a motor, M_2, as diagrammatically shown in Fig. 16 II., has been called a "magnetic

* A lecture delivered before the Franklin Institute, at Philadelphia, February 24, 1893; and before the National Electric Light Association, at St. Louis, Mo., March 1, 1893.

lag motor," but this expression may be objected to by those who attribute the rotation of the disc to eddy currents circulating in minute paths when the core, *i*, is finally subdivided. In order to operate such a motor effectively on the plan indicated, the frequencies should not be too high, not more than 4,000 or 5,000, though the rotation is produced even with 10,000 per second, or more.

In Fig. 16 I., a motor, M_1, having two energising circuits, A and B, is diagrammatically indicated. The circuit A is connected to the line, L, and in series with it is a primary, P, which may have its free end connected to an insulated plate, P_1, such connection being indicated by the dotted lines. The other motor circuit, B, is connected to the secondary, S, which is in inductive relation to the primary, P. When the transformer terminal T_1, is alternately electrified, currents traverse the open line, L, and also circuit A and primary, P. The currents through the latter induce secondary currents in the circuit, S, which pass through the energising coil, B, of the motor. The currents through the secondary, S, and those through the primary, P, differ in phase 90deg., or nearly so, and are capable of rotating an armature placed in inductive relation to the circuits, A and B.

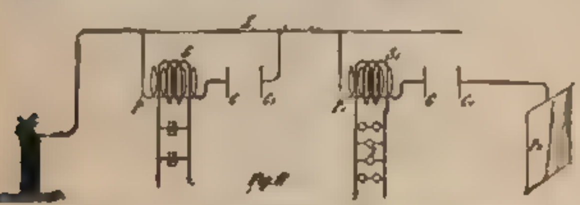
the other end to the condenser plates, C and C^1, respectively. Near these are placed other condenser plates, C_1 and C_1^1, the former being connected to the line, L, and the latter to an insulated larger plate, P_2. On the primaries are wound secondaries, S and S_1, of coarse wire, connected to the devices *m* and *d* respectively. By varying the distances of the condenser plates, C and C^1, and C_1 and C_1^1, the currents through the secondaries, S and S_1, are varied in intensity. The curious feature is the great sensitiveness, the slightest change in the distance of the plates producing considerable variations in the intensity or strength of the currents. The sensitiveness may be rendered extreme by making the frequency such that the primary itself without any plate attached to its free end satisfies, in conjunction with the closed secondary the condition of resonance. In such condition an extremely small change in the capacity of the free terminal produces great variations. For instance, I have been able to adjust the conditions so that the mere approach of a person to the coil produces a considerable change in the brightness of the lamps attached to the secondary. Such observations and experiments possess of course at present chiefly scientific interest, but they may soon become of practical importance.



Ways of Operating Motors with only One Lead.

In Fig. 16 III., a similar motor, M_3, with two energising circuits, A_1 and B_1, is illustrated. A primary, P, connected with one of its ends to the line, L, has a secondary, S, which is preferably wound for a tolerably high E.M.F., and to which the two energising circuits of the motor are connected, one directly to the ends of the secondary and the other through a condenser, C, by the action of which the currents traversing the circuit, A_1 and B_1, are made to differ in phase.

In Fig. 16 IV. still another arrangement is shown. In this case two primaries, P_1 and P_2, are connected to the line, L—one through a condenser, C, of small capacity, and the other directly. The primaries are provided with secondaries, S_1 and S_2, which are in series with the energising circuits, A_2 and B_2, and a motor, M_2, the condenser, C, again serving to produce the requisite difference in the phase of the currents traversing the motor circuits. As such phase motors with two or more circuits are now well known in the art, they have been here illustrated diagrammatically. No difficulty whatever is found in operating a motor in the manner indicated or in similar ways, and although such experiments up to this day present only scientific interest, they may at a period not far distant, be carried out with practical objects in view.



Single Wire Conversion and Distribution, with Simple Means for Regulating the Effects.

It is thought useful to devote here a few remarks to the subject of operating devices of all kinds by means of only one leading wire. It is quite obvious, that when high frequency currents are made use of, ground connections are—at least when the E.M.F. of the currents is great—better than a return wire. Such ground connections are objectionable with steady or low-frequency currents on account of destructive chemical actions of the former and disturbing influences exerted by both on the neighbouring circuits, but with high frequencies these actions practically do not exist. Still, even ground connections become superfluous when the E.M.F. is very high, for soon a condition is reached when the current may be passed more economically through open than through closed conductors. Remote as might seem an industrial application of such single wire transmission of energy to one not experienced in such lines of experiment, it will not seem so to anyone who for some time has carried on investigations of such nature. Indeed, I cannot see why such a plan should not be practicable. Nor should it be thought that for carrying out such a plan currents of very high frequency are implicitly required, for just as soon as potentials of, say, 30,000 volts are used, the single-wire transmission may be effected with low frequencies, and experiments have been made by me from which these inferences are made.

When the frequencies are very high it has been found in laboratory practice quite easy to regulate the effects in the manner shown in diagram, Fig. 17. Here two primaries, P and P, are shown, each connected with one of its ends to the line, L, and with

Very high frequencies are, of course, not practicable with motors on account of the necessity of employing iron cores. But one may use sudden discharges of low frequency and thus obtain certain advantages of high frequency currents without rendering the iron core entirely incapable of following the changes, and without entailing a very great expenditure of energy to the core. I have found it quite practicable to operate with such low frequency disruptive discharges of condensers alternating current motors. A certain class of such motors which I advanced a few years ago, which contain closed secondary circuits, will rotate quite vigorously when the discharges are directed through the exciting coils. One reason that such a motor operates so well with these discharges is that the difference of phase between the primary and secondary currents is 90deg., which is generally not the case with harmonically rising and falling currents of low frequency. It might not be without interest to show an experiment with a simple motor of this kind, inasmuch as it is commonly thought that disruptive discharges are unsuitable for such purposes. The motor is illustrated in Fig. 18. It comprises a rather large iron core, *i*, with slots on the top into which are embedded thick copper washers, *c c*. In proximity to the core is

Operating a Motor by Disruptive Discharges.

a freely movable metal disc, D. The core is provided with a primary exciting coil, C, the ends, *a* and *b*, of which are connected to the terminals of the secondary, S, of an ordinary transformer, the primary, P, of the latter being connected to an alternating distribution circuit or generator, G, of low or moderate frequency. The terminals of the secondary, S, are attached to a condenser, C, which discharges through an air-gap, *d d*, which may be placed in series or shunt to the coil C. When the conditions are properly chosen the disc, D, rotates with considerable effort and the iron core, *i*, does not get very perceptibly hot. With currents from a high frequency alternator, on the contrary, the core gets rapidly hot and the disc rotates with a much smaller effort. To perform the experiment properly it should be first ascertained that the disc, D, is not set in rotation when the discharge is not occurring at *d d*. It is preferable to use a large iron core and a condenser of large capacity so as to bring the superimposed quicker oscillation to a very low pitch, or to do away with it entirely. By observing certain elementary rules I have also found it practicable to operate ordinary series or shunt direct-current motors with such disruptive discharges, and this can be done with or without a return wire.

Among the various current phenomena observed perhaps the most interesting are those of impedance presented by conductors to currents varying at a rapid rate. In my first paper before the American Institute of Electrical Engineers, I have described a few striking observations of this kind. Thus I showed that when such currents or sudden discharges are passed through a thick metal

bar there may be points at the bar only a few inches apart, which have a sufficient potential difference between them to maintain at bright incandescence an ordinary filament lamp. I have also described the curious behaviour of rarefied gas surrounding a conductor to such sudden rushes of current. These phenomena have been since more carefully studied, and one or two novel experiments of this kind are deemed of sufficient interest to be described.

With reference to Fig. 19a, B and B_1 are very stout copper bars connected at their lower ends to plates, C and C_1, respectively, of a condenser, the opposite plates of the latter being connected to the terminals of the secondary, S, of a high tension transformer, the primary, P, of which is supplied with alternating currents from an ordinary low frequency dynamo, G, or distribution circuit. The condenser discharges through an adjustable gap, $d\ d$, as usual. By establishing a rapid vibration it was found quite easy to perform the following curious experiment. The bars, B and B_1, were joined at the top by a low voltage lamp, l_3; a little lower was placed by means of clamps, $c\ c$, a 50 volt lamp, l_2, and still lower another 100 volt lamp, l_1, and finally at a certain distance below the latter lamp, an exhausted tube, T. By carefully determining the positions of these devices it was found practicable to maintain them all at their proper illuminating power. Yet they were all connected in multiple arc to the two stout copper bars and required widely different pressures. This experiment requires, of course, some time for adjustment, but is quite easily performed.

Fig 19a. Fig 19b. Fig 19c.

Impedance Phenomena.

In Figs. 19b and 19c, two other experiments are illustrated, which, unlike the previous experiment, do not require very careful adjustments. In Fig. 20b, two lamps, l and l_1 (the former a 100 volt and the latter a 50 volt) are placed in certain positions as indicated, the 100 volt lamp being below the 50 volt lamp. When the arc is playing at $d\ d$, and the sudden discharges passed through the bars, B B, the 50 volt lamp will as a rule burn brightly, or at least this result is easily secured, while the 100 volt lamp will burn very low or remain quite dark, Fig. 19b. Now the bars, B B, may be joined at the top by a thick cross bar, B_2, and it is quite easy to maintain the 100 volt lamp at full candle power while the 50 volt lamp remains dark, Fig. 19c. These results, as I have pointed out previously, should not be considered to be due exactly to frequency, but rather to the time rate of change which may be great even with low frequencies. A great many other results of the same kind equally interesting, especially to those who are only used to manipulate steady currents, may be obtained, and they afford precious clues in investigating the nature of electric currents.

In the preceding experiments I have already had occasion to show some light phenomena, and it would be now proper to study these in particular; but to make this investigation more complete I think it necessary to first make a few remarks on the subject of electrical resonance, which has to be always observed in carrying out these experiments.

(To be continued.)

PHYSICAL SOCIETY.—June 23, 1893.

Prof. A. W. Rücker, M.A., F.R.S., President, in the chair.

Prof. J. Cox, M.A., was elected a member of the society.

Mr. F. H. Nalder exhibited a bridge and commutator for comparing resistances by Prof. Carey-Foster's method, the chief features of which are simplicity, compactness, long range, and great accuracy. The commutation of the coils to be compared is effected by mercury cups, the eight holes necessary for this purpose being arranged in a circle. An ebonite disc carrying the four connectors is mounted on a spindle in the middle of the circle, and the positions of the coils are interchanged by rotating the disc through 180deg. A large range is secured by providing a number of interchangeable bridge wires, and a fine adjustment for the galvanometer key enables great accuracy to be attained.

Mr. W. R. Pidgeon and **Mr. J. Wimshurst** each read a paper on "**An Influence Machine**," and exhibited their machines in action. In designing his machine Mr. Pidgeon has endeavoured (1) to make the capacity of each sector large when being charged, and small when being discharged; (2) to prevent leakage from sector to sector as they enter or leave the different fields of induction; and (3) to increase the capacity of the machine by making the sectors large and numerous. The first object is attained by arranging fixed inductors of opposite sign to the sectors near the charging points, and of the same sign near the places of discharge. Objects (2) and (3) are secured by embedding the sectors in wax, run in channels in the ebonite discs which form the plates of the machine, and carrying wires from each sector through the ebonite, each wire terminating in a knob. In this way the sectors can be placed much nearer together than otherwise without sparking back. By setting the sectors skew with the radius, they are caused to enter the electric fields more gradually, consequently the potential difference between adjacent sectors is kept comparatively small. Experiment showed that the use of the stationary inductors at the charging points increased the output threefold, and as compared within an ordinary Wimshurst the output for a given area of plate passing the conductors was as 5·6 : 1. The recovery of the machine after a spark had occurred was particularly rapid. Mr. Wimshurst's new machine consists of two glass discs 3ft. 5in. diameter, mounted about ¾in. apart on the same spindle. Both plates turn in the same direction. Between the discs are fixed four vertical glass slips over 4ft. long, two on each side, and each covering about three-eighths of a disc. Each slip carries a tinfoil inductor, which has a brush touching lightly on the inside of the adjacent disc, on its leading edge. Collecting and neutralising brushes touch the outsides of the discs and the few metallic sectors attached thereto. An account of some experiments made to determine the efficiency of the machine was given. The author also showed that when all the circuits of the machine were broken, it still continued to excite itself freely, and sparked from the discs to the hands when brought near.

In a written communication, **Prof. O. Lodge** said his assistant, Mr. E. E. Robinson, constructed a machine on lines similar to Mr. Pidgeon's a few months ago, and had now a large one nearly completed. Mr. Robinson's fixed inductors are carried on a third plate fixed between the two movable ones. The sectors are quite small, and neither they nor the inductors are embedded. On close circuit the machine gives a large current ($\frac{1}{20000}$ ampere) and on open circuit exceedingly high potentials. In Dr. Lodge's opinion, Mr. Pidgeon attaches too much importance to his sectors and their shape.

Mr. J. Gray wrote to say that stationary inductors enclosed in insulating material would probably give trouble at high voltages, because of the surface of the insulator becoming charged with electricity of opposite sign to that on the inductor. He suggested that this might explain why Mr. Pidgeon could not obtain very long sparks.

Prof. C. V. Boys enquired as to how far the wax made insulating union with the ebonite, for if good, glass might possibly be used instead of ebonite. He greatly appreciated the design of Mr. Pidgeon's machine.

A paper on "**A New Volumenometer**" by **Mr. J. E. Myers, B.Sc.**, describing the developed form of Prof. Stroud's instrument was, in the absence of the author, taken as read.

Mr. R. W. Paul exhibited a compact form of sulphuric acid voltameter of small resistance. The voltameter is a modification of a pattern designed at the Central Institution, in which the rate of decomposition is determined from the time required to fill a bulb made in the stem of a thistle funnel. He also showed a handy form of Daniell cell devised by Prof. Barrett. When not in use, the porous pot containing the zinc is removed from the copper sulphate solution and placed in a vessel containing zinc sulphate or sulphuric acid.

A paper on "**Long Distance Telephony**," by **Prof. J. Perry, F.R.S.**, assisted by **Mr. H. A. Beeston**, was read by Prof. Perry. The case of a line of infinite length, having resistance, capacity, self-induction, and leakage, is taken up, and the state of a signal as it gets further and further away from the origin is considered. Taking the shrillest and gravest notes of the human voice to have frequencies of about 950 and 95 respectively, the distance from the origin at which the ratio of the amplitudes of these high and low frequency currents is lessened by 1/mth of itself, has been determined when $m = 4$ for different values of leakage and self induction; and under similar conditions the distances at which the relative phase of the two currents become altered by 1/nth of the periodic time of the most rapid one, have been worked out for $n = 6$. The results are given in the form of tables, from which it appears that, if there was no self induction, increasing the leakage increases the distance to which we can telephone, whilst if there was no leakage, increasing the self induction increases the distance. When self induction and leakage are not too great, increasing either increases the distance, and for particular values the distances become very large. At the end of the paper, tables of general application are given, from which the limiting distances for any line can be readily found by multiplying the numbers by simple functions of the constants of the line.

COMPANIES' MEETINGS.

ELECTRIC CONSTRUCTION CORPORATION, LIMITED.

In our last issue we reproduced the circulars issued by the Directors of this Corporation with regard to the proposed reconstruction of the Company. In accordance with these circulars, meetings were held on Wednesday at the offices of the Corporation, at Worcester House, Walbrook, of the holders of first and second mortgage debentures, when the resolutions mentioned in the circulars were passed.

A meeting of the shareholders was subsequently held at the Cannon-street Hotel, Sir Daniel Cooper, Bart. (chairman), presiding.

The Chairman said that he had expressed on the occasion of the last meeting that the Board was in course of being reconstituted. The Board had been reconstituted, and during the past year seven gentlemen had retired from the Board, and three new Directors—Mr Bennett, Mr Barclay, and Mr Garcke—had been appointed. There was therefore practically a new Board, and he was very grateful for the changes that had been made. He had had occasion to mention at the last general meeting that Mr Courtenay had during the difficult period of transition taken up the reins of management, and had prepared the way for the Corporation making the important changes referred to. Since then he had been assisted by the new Directors, and the Board considered that they had been fortunate in securing the services of Mr Garcke as managing director. One of the first things that had had to be done was to cut down the very heavy standing charges, and the Managing Director would tell them what had been done in the direction of effecting economies. Then the financial position presented many difficulties, and it was only by the Directors coming forward and assisting the Corporation, and undertaking responsibilities for the Corporation, that they were able to meet their various engagements. The result of their investigation was that a thorough reorganisation of the business, and a reconstruction of the Company was absolutely necessary. The Board were convinced that the best way to carry out the reorganisation was by means of the scheme of reconstruction now before them, and by the formation of a new company. At present the credit of the Company was prejudiced by the shares being at a large discount, and this made it very difficult for the managers to get contracts and to carry on the business economically. The position of the Company was by no means what the price of the shares indicated, and he was expressing the views of his colleagues as well of himself when he stated that it was their belief that, with the careful management and energy with which they intended to push the business, there was a prosperous future before the new Company. The important contracts which had been entrusted to them, and which they had carried out successfully, by the aid of their works director (Mr Parker), had laid the foundation of profitable work in future. He then proposed the first special resolution: "That it is desirable that the Corporation be reconstructed, and that with a view to such reconstruction the Corporation be wound up voluntarily."

Mr Emile Garcke (the managing director) in responding to the call of the Chairman, hoped to give them reliable evidence that the Corporation had turned over a new leaf, and that there was reason for the hope that the errors of the past would not be continued in the future. He said that the new Board had acted very much in the capacity of a committee of investigation. A thorough reorganisation of the business had been taken in hand, and that would show the wisdom of the course taken at the last general meeting in leaving it to the new Board to carry out the investigation that they all felt necessary, particularly as the Directors had been able, in the course of their investigations, to put into effect such reforms as the result of their investigations proved to be desirable. With regard to the position of the Company when the new Board entered upon its work a few months ago, he mentioned that generally, while they were bound to recognise that there had been mismanagement in the past, the Directors were satisfied that, with strict economy and prudent management in the future, there was no reason whatever why they should not retrieve the errors of the past and occupy a leading position, and in many respects, the leading position in the electrical industry. It was difficulty to realise how very extensive had been the reorganisation of the Company's affairs. Some of the interests of the Corporation had been in the hands of separate companies with organisations of their own, and although the Corporation had the responsibilities of financing these subsidiary companies, they had not the full control of their management. Another disadvantage of this position was that the expenses of administration were unnecessarily and even excessively high, and the transactions between these several companies and the parent Corporation resulted in complications very often difficult to unravel. One of the first duties therefore, of the new Board was to get control of these subsidiary companies in such a way that they could reduce the expenses and minimise the friction, and very considerable progress had been made in this direction. Most of the subsidiary companies were now under the direct control of the Board, and, instead of there being separate officials the work of the subsidiary companies was largely done by the present staff of the Corporation. In this way very great savings had been effected. The financial position of the Corporation also at that time was not at all satisfactory, apart from the claims which these subsidiary companies made upon the Corporation, there were numerous liabilities and claims which were not properly defined, and which had been neglected. There again the Board had succeeded in improving the position. They had consolidated the liabilities of the Company in such a way that they were now in a far better position for dealing with them; but the settlement of many of those matters had involved the locking up of large sums of money in various securities and properties. There was still much to be done before they would be in what the Board considered a thoroughly sound financial and commercial position; but after what they had gone through and accomplished they were not going to be discouraged by the lesser difficulties still lying before them. Many of their investments were of such a character that, if properly developed and taken care of, promised not only to become valuable and realisable in cash, but would, he hoped, have the effect of largely increasing the business of the Corporation. They included shares and debentures in electric lighting companies, electrical and chemical manufacturing companies, tramway companies, and other concerns. Some of these were really fine properties, and brought in satisfactory dividends without causing much trouble. Others, however, might not be so good. In the first instance, the Electrical Power Storage Company, of which the Corporation held a large proportion of the capital, yielded them annually sufficient to pay the full interest on the first mortgage debentures. Another company, about which, however, they did not feel quite so happy, was the General Electric Power and Traction Company. They had a large stake in that company, some of which must be looked upon as lost, but that was provided for in the valuations upon which the scheme of reconstruction was based. Among the electricity supply companies in which they had shares and debentures were the Chelsea Electricity Supply Company, the Oxford Electric Company, and the Crystal Palace District Electric Supply Company. The first of these was now paying dividends, and the other two possessed successful electric light stations which were now rapidly increasing the number of lights. Then there were several subsidiary companies formed to develop electro-chemical patents of great promise, in which they had large interests. If these turned out successful, good profits should be made, and personally he had much confidence in the future of the electro-chemical industry. Another investment their predecessors had made was in the South Staffordshire Electric Tramways. This would, he thought, prove remunerative eventually, and would no doubt lead to their getting further business, but, nevertheless, in the present form it was an inconvenient lock-up of capital. Electric traction was going to be a very important industry, and from that point of view it was very desirable that they should be first in the field. Coming to consider the scheme of reconstruction, the Board had first in view the preparation of a scheme which should be fair and equitable to all interests. It had received the most careful consideration of the Board and of their legal advisers, and they were much gratified by the general support which had been given to it by the shareholders as well as by the debenture holders. At the two meetings that morning the proceedings passed off satisfactorily. Of the £150,000 debentures, only £126,000 had been subscribed and paid for, as mentioned in the schedule. The balance of £24,000 had not been taken up, but had been issued by the Corporation and deposited as security for advances. Upon these claims being paid off those debentures would be released and would be available for issue. Then of the £100,000 second mortgage debentures, only £50,000 were taken up last December, and the other £50,000 remained in the hands of the Company. Since then this second £50,000 had been deposited as security in consideration of advances made to the Corporation or liabilities undertaken on behalf of the Corporation. The first and second mortgage debentures would remain untouched. With regard to the income bonds, their conversion into ordinary shares was a desirable arrangement in the interests of the ordinary shareholders. It was true the ordinary shares to be issued in lieu of the income bonds would immediately rank for dividend, which was an advantage to the holders of the income bonds, but on the other hand, they gave up their claim to rank in front of the ordinary shares in a distribution of assets, and they also gave up their right to be paid off. That was very important to the ordinary shareholders. It was unfortunate that the burden of the loss should fall upon the subscribers of the original capital; but they were the real owners of the business, and those who had come in afterwards with their money were more in the nature of creditors whose interest in the business was defined by the arrangements which they had made with the original subscribers. The Directors were advised that legally the founders were, under the scheme, not entitled to anything, but, as he had already said, the desire of the Board had been to prepare a scheme which should be as equitable as possible, and if they approved of the founders being placed upon the same footing as the ordinary shareholders, they could carry out the arrangement in giving them £4 in ordinary shares in respect of each founder's share. That gave the founders an advantage, because at present they were not entitled to anything until the ordinary shareholders had received 10 per cent., whereas, under the new arrangement, they would at once rank with the shareholders, although only for a small amount; on the other hand, it was of great advantage that the founders' shares should be abolished. It would be seen from the schedule that the new capital was there put at £519,260, but the whole of this might not be issued at once. He had already referred to the £24,000 first mortgage debentures and to the £50,000 second mortgage debentures, and, in respect to the last item, there were 10,000 ordinary shares, representing £20,000, for which the scheme must provide, in case they should have to be exchanged for the £50,000 income bonds attached to the second mortgage debentures. Then it must be remembered that the second mortgage debentures were being reduced by half yearly drawings, and the first drawing had already taken place, and £2,000 had been paid off. Thus the capital of the new company would not be so large as appeared in the schedule, but, of course, the scheme must provide for every existing contingent or pos-

sible claim. The nominal capital would be £400,000, of which £300,000 would be in ordinary shares and £100,000 in preference shares, but as the ordinary shares to be issued would be at the outside £240,000, there would be a surplus of £60,000, and perhaps £80,000 of ordinary capital available for issue. Then of the preference share capital there would be available for future issue upwards of £70,000. Of course the desire of the Board was to keep the capital down as low as possible. Although the measures proposed were drastic, they were wise, and such as prudent men of business ought to face. At present the shares were at a heavy discount in the market, and the Company was suffering in name and credit. That was all by reason of the disrepute into which the Company had fallen in consequence of its late unfortunate associations. He asked them to put an end to all that, and let the Company turn its back upon the past and go forward and compete with others, and share with others upon equal terms the work which lay before them. He then referred in general terms to what had led up to the loss of capital. He was not going to commit himself to any definite promises as to the dividends they would be able to pay. No one could be absolutely sure of the future, but he did not mind promising them one thing on behalf of the Board and of the staff and that was that they would spare no efforts to keep down expenses, to increase the volume of profitable business, and to raise in every way the name and credit of the Company. There were some legal reasons why the reconstruction must be carried out if they wanted to receive dividends in future; but he would not trouble them with a statement of those. It did not affect their pockets at all, whether they received 6 per cent. on a share having a face value of £10, or 12 per cent. on a share having a face value of £5, but it would improve their position very much if, as a result of the reconstruction, the market value of the shares improved. Before concluding he referred to a matter which afforded him some satisfaction. That was that the technical work of the Corporation had invariably been carried out with entire satisfaction to their customers, as, for instance, at Liverpool and the electric tramways in South Staffordshire. In the case of machines recently supplied to an important corporation they were entitled to a handsome bonus, because the machines proved more efficient than was specified. He could multiply instances of that kind. He then seconded the resolution proposed by the Chairman.

After some discussion all the resolutions given in our last issue were put to the meeting and unanimously carried.

A vote of thanks to the Chairman brought the proceedings to a close.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY, LIMITED.

The half yearly general meeting of this Company was held on Wednesday at the Cannon-street Hotel, E.C., to obtain the sanction of the shareholders to the payment of an interim dividend of 5 per cent., or 10s. per share, free of income tax. Mr W. S. Silver (chairman) presided.

The Secretary (Mr. William J. Tyler) having read the notice convening the meeting,

The **Chairman**, in moving the adoption of the motion, said: We are very glad to see you. You may perhaps remember on the last occasion I referred to a cable that we had just manufactured, between 2,000 and 3,000 miles, which we were about then to lay in the Pacific. That work has been completed and paid for. Referring to it, I believe I am justified in saying that it is one of the best cables that we have made. In reference to trade generally I am very glad to say that the returns are equal to previous years—somewhat in excess. I do not know that I can add to these remarks. I will ask my friend, the managing director, to give you a report of the French works, to which he has just paid a visit, and will conclude by moving that a dividend of 5 per cent., or 10s. per share free of income tax, payable on 6th inst., be now declared.

Mr A. Scott seconded the motion, which was unanimously adopted.

Mr Matthew Gray (managing director) stated: As the chairman has just said, I have been visiting our French works recently within the last few weeks, and I am glad to report that everything is going on there satisfactorily. We have a very nice little works there, and are doing very good work, and I think we are doing it on a proper basis and one that will give a moderate return for our exertions. I do not think that the shareholders need be at all anxious about the French works. I think they are in a very good position, and likely to be satisfactorily managed. I do not know that I have anything else to say as far as the French works are concerned. I regret to tell you that one of our agents for Ireland has died during the last month, a man who had been with us for 19 years, a very worthy, decent fellow he was, but he died about three weeks ago of heart disease. I went over to Ireland about 10 days ago for the purpose of making arrangements for carrying on our Irish business, and I have just returned. I think I have made such arrangements as will prove satisfactory. Although I must express my sincere regret for the loss of our worthy agent, still I think under the circumstances probably it will turn out not so injurious as we might have expected. I think the arrangements now made are such as will enable us to carry on our Irish business in as satisfactory a manner as hitherto. I do not think I have anything else to say. The works at Silvertown are in a satisfactory condition, and everything is going on in the usual manner and I think satisfactorily. I think we could do more cable work if we had it to do.

Mr Martindale proposed, and **Mr. Treble** seconded, a vote of thanks to the Directors and others connected with the business, this concluding the proceedings.

EDINBURGH ELECTRIC SUPPLY CORPORATION.

A special meeting of the Edinburgh Electric Supply Corporation, Limited, was held in Edinburgh on the 28th ult. for the purpose of considering a resolution for voluntarily winding up the Company under the provisions of the Companies' Acts. Mr Walter Berry (chairman of the Company) presided, and there was an attendance of about twenty gentlemen.

The **Chairman** made a few remarks regarding the initiation of the Corporation, which was registered on April 14, 1890, the shareholders being nearly all Edinburgh citizens. The Directors had had every reason to expect that the Town Council would entrust that company with the work of lighting the city, but a majority of the Council had overruled the opinions of representative citizens. The romance of the shareholders was now ended. The Town Council had taken away their bride, and now that they were married he hoped they would live together happily ever afterwards, and that the progeny would not be too troublesome or contentious, or involve loss to the ratepayers. He most sincerely trusted that the Council would carry on the business to their own and to the citizens' satisfaction. He had no hesitation in asserting that had the authorities decided to entrust the electric lighting of the city to the Company, the result would have been satisfactory to the shareholders, the community, and to the honour of Edinburgh. He concluded by formally moving the resolution that the Company should be voluntarily wound up.

Sir Thomas Clark, in seconding the resolution, said although the Company was not to go on, he was very glad the Town Council had taken up the work, and he hoped they would meet with every success.

The resolution was unanimously agreed to.

Mr. F. T. R. Deas, in acknowledging the resolution on behalf of himself and his colleagues, said the guarantors of the preliminary expenses were the seven directors and Mr. John H. Robertson, stockbroker, and although the officials had tried hard to keep down the expenses still they amounted to a very considerable sum, and they had been paid up by the gentlemen mentioned without a murmur. Not only so, but the guarantors stood to lose a very much larger amount had occasion demanded, and he was sure the shareholders would fully recognise that their scheme could never have reached the important position to which it attained had it not been for the financial support of the guarantors.

On the motion of **Mr. J. H. Balfour, W.S.**, a vote of thanks was passed to the Directors and the Chairman for their services, and the meeting terminated.

UNITED RIVER PLATE TELEPHONE COMPANY.

The seventh annual general meeting of the shareholders of the United River Plate Telephone Company, Limited, was held on Tuesday at Winchester House, Old Broad-street, E.C.

Mr J. Irving Courtenay presided, and, in moving the adoption of the report, said the opinion he expressed last year, to the effect that they had seen the worst of the trouble in the Argentine Republic, had come to pass. There had been from time to time periods of depression and of uncertainty, but the net results had been satisfactory. The average of the premium on gold in the year under review had been 215 as contrasted with 280 in the year before. The receipts of the Company had increased during the year from £98,699, at par of exchange—the amount received during the previous year—to £115,341. The expenses were slightly smaller, and, as they were now at a minimum, an increase must be expected as the business grew. The number of subscribers had increased by 710 during the year, against a loss of 125 in 1891-92. The working of the year showed a profit of a little over £7,000, but the policy of the Board was to consolidate and strengthen the position of the Company, and to that end they had dealt with the sum in a manner which, he hoped, would meet with the shareholders' approval. They had written off the balance of the taxes suspense account, £768, and £2,728 in respect of bad debts. They had also transferred £3,000 to the depreciation and renewal fund, and there still remained a balance of £540 to be carried forward. Notwithstanding the fall in the gold premium, the loss in exchange was greater than in the previous year, the explanation being that as the net receipts in the River Plate, at par of exchange, were nearly 50 per cent. more, the loss in conversion, notwithstanding the lower gold premium, was considerably larger. The loan from the bankers of £2,100, which appeared in the previous balance-sheet, had been paid off. They had just paid off the holders of the balance of the 7 per cent. debentures, who declined to convert into 5 per cent. debenture stock.

Mr. F. W. Jones seconded the motion, which was adopted.

Birmingham.—A meeting of the City Council was held on Tuesday, the Mayor (Hon. P. Allsopp, M.P.) presiding. The Mayor stated, on behalf of the Watch Committee, that the tenders for erecting the electric light station at Powick exceeded their anticipations, and they thought it desirable there should be some delay before recommending any action. He then moved a resolution to obtain a report on the cost of making navigable the River Teme. Mr Chamberlain Millington moved an amendment that the committee should be instructed to report on the cost of an alternative scheme of a steam generating station in the city. Both resolution and amendment were withdrawn—conditionally that the committee would report on the relative cost of a water power scheme at Powick and steam power in the city—until definite proposals were brought forward.

BUSINESS NOTES.

Sheffield.—The new post office at Sheffield is lighted throughout with 250 electric lights.

Richmond.—Work is being actively pushed forward in main-laying at Richmond, Surrey.

Great Northern Telegraph Company.—The receipts for the month of June amounted to £24,800.

Western and Brazilian Telegraph Company.—The receipts for the week ended June 30 were £2,369.

Ostend.—Tenders will be received by the municipality of Ostend for electric lighting to September 15.

Direct Spanish Telegraph Company.—The receipts for the month of June were £236 less than for the corresponding period.

Cuba Submarine Telegraph Company.—The receipts for the month of June were £220 less than for the corresponding period.

West India and Panama Telegraph Company.—The receipts for the two weeks ended June 30 were £96 more than for the corresponding period.

Dunfermline.—Messrs. R. E. Walker, Reid, and Co., manufacturers, Albany Works, are having the electric light introduced into their works.

Eastern Extension Telegraph Company.—The receipts for the month of June show an increase of £3,705 as compared with the corresponding period.

City and South London Railway Company.—The receipts for the week ending July 2 were £811, against £763 for the same period last year, or an increase of £48. The total receipts for 1893 show an increase of £1,715 over those for the corresponding period of 1892.

Kendal.—At a meeting of the Kendal Town Council last week, in the minutes of the Town Hall Improvement Committee it was stated that as regards the question of lighting the improved Town Hall premises with electric light, the committee were not yet in a position to say anything definite.

Liege.—Six tenders were submitted for lighting Liege—from Messrs. Van Rysselberghe, Antwerp; Siemens and Halske; M. Pieper, Liege (three tenders); and M. Jaspar, of Liege. The tenders varied widely in amount—from £20,000 up to £50,000—and also in proposed tariff—from 5d. to 7d. per unit. The decision was adjourned.

Illuminations.—For the illuminations on July 6 Messrs. Rashleigh Phipps have some very unique ideas at the following places: Messrs. Mooney and Co., Strand; Messrs. Mooney and Co., 19, High Holborn; Messrs. Kirkman and Son, 12A, George street, Hanover square; Messrs. Peal and Co., 487, Oxford street; and their own premises.

Telephones for Leamington.—A telephone exchange has been established at Leamington. In future Leamington will be able to answer satisfactorily to the question, "Hullo! Are you there?" At the opening, telephones in the Mayor's parlour were placed in communication with the Savoy, the Shaftesbury, the Empire, and other places of amusement in London.

The Paragon.—The Paragon, Mile End road, is now closed for alterations, and Messrs. Vaughan and Brown, 15, 16, and 17, Kirby street, E.C., are laying down specially designed electrical plant for generating the electric current, and also installing the whole of the building with massive electroliers and brackets. They are also laying down a specially arranged heating apparatus for warming the building.

City of London Electric Lighting Company.—The Directors of this Company have declared an interim dividend of 5s. 4d. per £10 share, less income tax, on the first issue of 20,000 cumulative 6 per cent. preference shares, Nos. 1 to 20,000 inclusive. The payment is calculated at the rate of 6 per cent. per annum on the respective instalments for the period ended June 30, 1893, and is payable on July 11 next.

Sutton (Surrey).—With regard to the scheme of electric lighting for Sutton, the General Purposes Committee proposed at the last meeting of the Sutton Local Board, that Mr. Segundo and Messrs. Girdlestone, Tatham, and Co. should be requested to report on the whole question. The matter was discussed at some length, and Mr. Wellington, as chairman of the committee, moved the adoption of the report. Mr. Hay seconded the motion, which was agreed to.

Proposed Extension at Bradford.—Mr. J. N. Shoolbred and Mr. S. W. Baynes, of the Bradford Corporation Electricity Supply Works, had an interview last week with Lord Kelvin on the subject of the method to be adopted to extend the electricity supply in Bradford. Lord Kelvin will present his report to the Electricity Supply Committee in due course, and the committee will then determine whether it is necessary to invite Lord Kelvin to explain his views on the matter in person.

Eastern Telegraph Company.—The accounts of this Company show, after placing about £88,000 to reserve fund, a balance available sufficient to pay the fixed dividend of 3s. per share, being at the rate of 6 per cent. per annum on the preference shares, less income tax, and a final payment of 2s. 6d. per share, with a bonus of 3s. per share, both tax free, on the ordinary shares, making with previous payments on account a total distribution of 6½ per cent. on those shares for the year ended March 31, 1893.

Electricity Supply Company for Spain.—The Directors of this Company invite tenders for the supply and erection of certain machinery, etc., for the extension of their electricity works in Madrid. Plan of buildings and statement of requirements, with terms and conditions of tender, may be obtained at the offices of the Company, 15, St. Helen's-place, London, E.C., on and after Monday next on payment of one guinea. Sealed tenders must be sent to Mr. P. A. Latham, secretary, by 11 a.m. on July 29.

Lancaster.—Major General Crozier, R.E., held a Local Government Board enquiry, last week, into an application made by the Town Council for sanction to borrow £25,000, the estimated cost of a system of electric lighting installation for the borough, to be provided by the Brush Electrical Engineering Company, of London. For the present the Corporation propose to light only the main streets in the centre of the town, but arrangements are being made so that additional plant may be put down as required.

Chelmsford.—Messrs. Deacon, Gibson, and Medcalf, the solicitors to Messrs. Crompton and Co., have written giving the Council notice of their intention to apply to Parliament for a provisional order under the Electric Lighting Acts for statutory powers within the borough. At the Town Council meeting, in reply to Alderman Durrant, the Town Clerk, said that powers under a provisional order were rather more extended than those under the license Messrs. Crompton now held. The letter was referred to the Lighting Committee.

The Gilgit Telegraph.—It is a matter for regret, says the *Indian Engineer*, that no commencement has been made on a telegraph line up the Khagan Valley. It is impossible to believe that the Government will not adopt this route as the permanent one, giving direct communication with Gilgit by way of Chilas, and it is difficult to understand why any delay occurs in coming to a decision on the subject. Several lakhs of rupees would be saved yearly, moreover, in provisioning the Gilgit garrison if the road over the Babusar Pass were to be made.

St. Pancras.—The Electricity Committee reported at the St. Pancras Vestry meeting that they had received an application from Messrs. Gilbey, wine merchants, Chalk Farm, to supply their premises with electric lighting. They would require 400 lights, and would enter into an agreement to consume for three years. Applications for electric lighting for districts near Regent's Park had also come in. The cost of laying the service would be about £2,650, but the annual income would be about £250. It was agreed that the committee at once proceed with the work.

National Telephone.—The Directors of the National Telephone Company, Limited, have resolved to recommend the following dividends, less income tax, for the last half of the financial year ending April 30 last: At the rate of 6 per cent. per annum on the amounts paid up on the first and second preference shares; at the rate of 5 per cent. per annum on the amounts paid up on the third preference shares; at the rate of 5 per cent. per annum on the amounts paid up on the ordinary shares, making, with the interim dividend already paid, 5 per cent. for the year, leaving a balance of about £32,000.

Madrid Tramways.—The Spanish correspondent of *Industries* states that a scheme has been presented to the different horse-tramway companies in Madrid to convert them all into electric tramways and work them for a period of 25 years at 3½d. per kilometre run (5½d. per mile), the plant and cars at the expiration of the concession to belong to the tramway companies. Capital to the extent of £400,000 will be required, which is expected to be raised in Germany. So far, it is stated, the tramway companies are reluctant to accept the proposal for several reasons, but in the end it will probably be carried out.

Barnsley.—If something is not done at once for the electric light at Barnsley the chance will be gone for some years. At the discussion of the renewal of the gas contract, Mr. Hawke raised the question of electric light, and said he thought they were to hear from Mr. Hammond as to a lecture as an advertisement for electricity. The Chairman said the Board did not see paying the expenses of a lecture for someone else to reap the benefit. He thought they were getting on amicably at present. The Gas and Lighting Committee, we understand, are to meet and consider the proposal, and if anyone wishes to put in particulars as to cost of electric lighting, then will be evidently the time.

Wigan.—At a special meeting of the Wigan Gas Committee last week, a letter was considered from the Corlett Electrical Engineering Company asking the Corporation to allow them to supply current to the new Royal and Ship Hotels, the new Mineral Waterworks, and the block of buildings to be erected in Millgate by Sir F. S. Powell, M.P. Mr. Corlett attended, and stated that he had been asked to tender for the supply of electric current to the places mentioned. He discussed the terms on which the company would cease to supply the electric current in case the Corporation decided at some future time to supply electricity themselves. Mr. Corlett was requested to submit the terms in writing.

Russian Tunnel.—While several subterranean railway tunnels of the most approved design are in process of planning or construction in London, we must look to Russia for something entirely novel in this respect, says the *Mining Journal*. A proposal has been laid before the Public Works Department at St. Petersburg to pierce under the Neva in the shape of a circular tunnel having a diameter of 43ft. The peculiarity of the subway design is in the provision of four floors or decks for pedestrians, vehicles, trams, and telegraphic cables respectively. Details as to the approaches are not to hand, but the cost of the tunnel construction is given at £400,000. It is not at all improbable that we shall hear more of "decked" tunnels, for subterranean work has come much to the front of late. In connection with the proposal under notice, it is remarkable that some of the greatest engineering schemes in this hemisphere are in progress, or on paper, in the Czar's dominions.

Rashleigh Phipps.—On Saturday, the 1st inst., the employes of Messrs. Rashleigh Phipps and Co., 102, Oxford-street, held their annual holiday at Brighton. The party proceeded by an early train, and after a couple of hours, spent either in or upon the sea, sat down to an excellent dinner, to which good justice was done. It is worthy of remark that excepting where business intervened there was no single absentee, every available man being present. After dinner the party proceeded by brake to Shoreham, and thence to Southwick, where an enjoyable cricket match was played on the village green. The proceedings throughout were carried on with marked enthusiasm, and the measure of success of the whole outing was such as is seldom attained on these occasions. This firm has since Mr Phipps dissolved partnership in November last carried out 65 installations (list of which we hold), and these installations, totalled up, run into 3,949 lights (private houses 1,378, business houses 2,000, temporary lighting 571 lights).

The National Transformer System.—Messrs. Shippey Bros., Limited, announce that they have been appointed sole European agents for the National Electric Manufacturing Company, of U.S.A., and send us illustrated catalogues of the various descriptions of electrical plant manufactured by the company, which includes alternating and direct current dynamos, electric motors, generators, ventilators, transformers, incandescent lamps, switch boards, and various other appliances. The National system appears to be very popular in the United States, and are apparently doing a very large business, as from list of complete installations carried out by the company up to January last, the work exceeded 200,000 lamps and over 1,000 h.p. in motors and generators. This large amount of work speaks well for the system, which is making rapid strides in America. The new multipolar generator manufactured by the National Company has several interesting features. We learn that Messrs. Shippey Bros. are making arrangements for holding stock in England for the leading types of machines for prompt delivery.

York.—At the meeting of the York City Council the town clerk reported that the Bill confirming the provisional order for the extension of the city, after passing through the House of Commons, had been read a first time in the House of Lords. The Electric Lighting Sub-Committee reported that after consideration of the report submitted to them by Prof. Kennedy, F.R.S., they had decided to recommended the committee to ask for the authority of the Council to accept the tender of Messrs. Siemens Bros. and Co. for the lighting of the city. Prof. Kennedy attended the meeting of the committee, and after the discussion of the recommendation of the sub-committee, it was resolved that the consideration of the recommendation be deferred until the whole committee has had an opportunity of considering an abstract of the reports submitted by Prof. Kennedy, such abstract to summarise the tenders of the following firms: Messrs. Crompton and Co., Limited; Messrs. Siemens Bros. and Co., Limited; Messrs. C. A. Parsons and Co.; and the Brush Electrical Engineering Company; and to contain a statement showing the comparative cost of production in each tender in the area first proposed to be lighted, and in the proposed extension of such area together with the amount required to pay interest and provide the sinking fund in connection with the capital outlay.

Blackpool.—The slow progress of the electric installation at Blackpool is causing fears that the lighting will not be ready when promised. "We understand," says the *Blackpool Gazette*, "that at a recent meeting the Highway Committee of the Corporation had under serious consideration the want of unanimity between the highway, gas, and electric lighting departments which has latterly been conspicuously evident. On several occasions lately the ratepayers have been treated to the edifying spectacle of footpaths and roads being remade and left in splendid condition one week, only to be uprooted for gas or electric lighting purposes a week or two following, and left in a disorder almost amounting to danger. These three important departments have obviously been working without prearrangement or consultation. One week a footpath might be pulled up to lay gas pipes, while the next week another section may be excavated to put down the electric lighting wires. If the departments had been working in harmony, as they ought to have been, a considerable amount of money would have been saved the ratepayers during the last six months alone. After considering this question, we understand the Highway Committee passed a comprehensive resolution insisting upon the necessity of the several departments working more in unison than has latterly been the case. The ratepayers will be glad to hear this fact, and they will hope to see a change for the better in this respect in the future."

The Scarborough Electric Station Chimney.—The works of the Scarborough Electric Lighting Company in Seamer-road are progressing satisfactorily, though there was at one time a fear that their completion would be delayed by an untoward incident. The most prominent feature of the works is a chimney of large proportions, which is some 130ft. high, for the boiler fires. It is built upon a solid block of concrete of 20ft. cubical section, upon a bed of clay. When nearly the maximum height, it was found a few weeks ago that a settling had occurred over the crown of the arch of the flue. This did not amount, at the point at which it occurred, to more than 2in., though it threw the shaft out of the plumb some 18in. at the top. Work was at once stopped in the structure, and experts were called in to give their advice. They reported that the chimney could be straightened by cutting the courses on the side opposite to that on which the settlement occurred. A meeting of the directors of the company was held, and the report of the experts was considered. They recommended the cutting of the courses, and the strengthening and buttressing of the chimney. In a discussion afterwards held, it was stated that in most cases of falls of chimney shafts the courses had previously been cut in order to straighten them. It was felt that it would be better to run no risks, and it was ultimately decided to pull the chimney partly down, and rebuild it again. It is satisfactory to learn that the incident will in no way delay the turning on of the light in Scarborough as the new shaft can be completed in time. Other work is forward, that of laying the main conduits in the compulsory area is now very nearly completed and in a few days the threading of the cables may be expected to commence. Wires are already laid through the pipes in order to facilitate this work.

Manchester Corporation Electric Lighting.—The Electric Lighting Department of the Manchester Corporation Gas Committee has prepared a report for the year ended March 31 last, for presentation to the City Council. The report, which is signed by Alderman Sir J. J. Harwood, chairman of the Electric Lighting Department, and Mr. Joseph Brooks, chairman of the Gas Committee, says: "The buildings at the electric lighting station, Dickinson street, for the accommodation of the engines, dynamos, boilers, etc., are now completed, and the following plant has been fixed in position—viz., six steel boilers, 8ft. by 30ft., steel tank, coaling stage, and crane, steam pipes, six 90 h.p. compound vertical engines, two 360-h.p. compound vertical engines, six dynamos (102 volts), two dynamos (410 volts), and two travelling cranes. The switch and instrument boards are in course of erection. With regard to the main conductors in the streets, one mile 100 yards of concrete culvert have been constructed, and about 65¼ tons of copper strip placed therein upon porcelain insulators. Two and a half miles of cast iron pipes have been laid, into which six miles of ⅝in. and five miles of ½in. insulated cable have been drawn. The works are rapidly approaching completion, and it is anticipated that current will be ready for consumers by the 1st August next." An abstract of accounts, attached to the report, shows that the amount sanctioned for the purposes of the Corporation Electric Lighting Order, 1890, was £80,000, and that of this sum £50,200 has been borrowed, £10,000 at 3 per cent. and £40,200 at 3½ per cent., leaving £29,800 sanctioned but not borrowed. The items of the total expenditure to March 31 are: Land, including law charges incidental to acquisition (on account), £2,161. 12s. 3d.; buildings, £9,337. 14s. 3d.; machinery, £13,196. 4s.; mains, £14,077. 1s. 11d.; electrical instruments, £41. 11s. 9d.; expenses prior to generating of electricity, £2,906. 6s. 10d.; making a total of £41,720. 10s. 8d., and leaving to balance of capital account, £8,479. 9s. 4d.

New Issue.—The Yorkshire House-to-House Electricity Company have a total authorised capital of £100,000, and have issued 7,366 shares of £5 each; 2,634 shares are now offered to the present shareholders for subscription. The money is wanted for the extension of works, and applications should reach the company's bankers on or before Monday, the 10th July. The following circular has been sent to the shareholders: "The directors have pleasure in reporting that the demand in Leeds for the electric light is so heavy as to make an immediate addition to the company's plant necessary, and they have therefore decided to offer for subscription the balance unallotted of the issue of 10,000 ordinary shares of £5 each—viz., 2,634 shares. The works have been so constructed that additions can be easily provided at a comparatively small outlay. The addition to the plant now proposed consists of a 200 i.h.p. engine, and dynamo to correspond, which will raise its capacity from 250 to 350 kilowatts, being an increase of 40 per cent., though at an increased expenditure of capital of less than 10 per cent. The importance of providing sufficient plant to enable the company to deal with all the business presented to it hardly needs enforcing; and the profit-earning capacity of the works may be expected to increase in even greater proportion than the output, as the cost of each unit of electricity supplied will naturally decrease with the increased production. The directors consider that the success already attained justifies them in regarding the company's shares as a safe and profitable investment, and they think it right to give the present shareholders the preference of subscribing the additional capital now required. It is proposed to call up 10s. per share on application and 10s. on allotment, and to make no further call on the shares now offered for subscription during the present year. The directors, who already hold more than one-fifth of the subscribed capital, propose to apply for an additional amount of not less than £3,000. If more than 2,634 shares are applied for, allotments will be made in proportion to the present holdings of the applicants. Copies of the original prospectus, and forms of application, may be obtained from the secretary. The contracts and documents referred to in the prospectus may be inspected at the offices of the company; and applicants for shares will be considered to have notice of any other contracts, and to have waived further compliance with Section 38 of the Companies Act, 1867; and allotments will only be made on this footing. Applications for shares should be made on the enclosed form, and sent with the deposit of 10s. per share to the company's bankers, Messrs. W. Wms. Brown and Co., Commercial-street, Leeds, on or before Monday, July 10."

Laying the Memorial-Stone at Cardiff.—An important step in the installation of the electric light in Cardiff by the Corporation was taken on Monday afternoon, when the Mayor laid the memorial-stone of the central station at which will be generated the supply. The station is in course of erection on Canton Common, near the Great Western Railway. In the form which is immediately contemplated, the site will be about 80ft. square. This, while amply sufficient for plant to supply current to the compulsory area in the centre and principal business part of the town, provides also, both as to site and the character of the buildings, for extensions being made from time to time with ease and economy. The cost of the

present portion of the scheme is £32,500, which includes the cost of a chimney 150ft. high—a structure, the extent and capacity of which is expected to meet present and future requirements. The buildings for which tenders have been let, and foundations already laid, will comprise engine and boiler houses, coal stores, etc., and there will be a private siding parallel to the existing sidings of the Great Western to the main line. It is proposed to lay 3in. cast iron pipes from the supply station to the compulsory area, and these, it is expected, will be sufficient to take cables for the whole of Cardiff being illuminated with the electric light, so that the taking up of the streets will be minimised. The first thing which it is proposed to do is to light the streets in the area indicated by means of 44 arc lamps. This will be brought about within the next three months, and by Christmas the Corporation will be able to supply every possible consumer within the district. The arc lights will be 22ft. above the street level, and wherever it is possible to do so they will be placed in the centre of the road. In selecting the site which was eventually fixed upon, the Electric Lighting Committee found that the utilisation of land already in possession of the Corporation would more than compensate for the extra length of cables to be laid connecting the town with the central station. In this respect they profited by the experience of Bournemouth, where the electrical supply station is nearly two miles out of the town. The stone-laying ceremony was performed in the presence of a goodly company, including the deputy mayor (Alderman Daniel Lewis, J.P.), and a full attendance of aldermen and councillors, the town clerk (Mr. J. L. Wheatley), the deputy town clerk (Mr. F. C. Lloyd), the borough engineer (Mr. W. Harpur), the electrical consulting engineer (Mr. W. H. Massey), and others. Before laying the stone, the Mayor gave a brief outline of the history of electric lighting in Cardiff, and having accepted a silver trowel and mallet at the hands of the borough engineer and Mr. Thomas (contractor), his worship placed in position the slab, which bears this inscription: "This memorial stone was laid by the Right Worshipful the Mayor of Cardiff, Councillor William Edward Vaughan, J.P., chairman of the Lighting and Electrical Committee of the Cardiff Corporation, on the 3rd day of July, 1893.—JOSEPH LARKE WHEATLEY, Esq. (town clerk); WILLIAM HARPUR, M.Inst.C.E., and WILLIAM H. MASSEY, M.Inst.C.E. (joint engineers); W. THOMAS AND CO. (contractors)." A cordial vote of thanks was passed to the Mayor, on the motion of Alderman D. Lewis (deputy mayor), seconded by Councillor Gerhold. The party having returned to town, they were entertained to luncheon in the Assembly room, Town Hall, by the Mayor. A number of toasts were honoured, amongst others being that of "Success to the Electric Light of Cardiff and the Mayor and Corporation." This was proposed by Mr. Lascelles Carr, who urged the importance of the Corporation having in their hands such undertakings as the lighting of the town and the waterworks, thus securing the control of their own streets. In responding to the toast, the Mayor said the town had suffered long enough by private companies possessing monopolies. Alderman Carey also responded, and prophesied a big future for the electric light in Cardiff. The toast was also spoken to by Alderman Thomas Rees, who was interestingly reminiscent as to the artificial lighting of the borough and its development. The remaining toasts were "The Architect and the Electrical Engineer," acknowledged by the borough engineer (Mr. W. Harpur) and Mr. W. H. Massey, and "The Builders and Contractors," replied to by Mr. Thomas and Mr. Chubb.

PROVISIONAL PATENTS, 1893.

JUNE 26.

12490. **Improvements in the means of conveying or administering electricity for medical purposes or others.** Edmond Savary d'Odiardi and Eva Savary d'Odiardi, 43, Cornwall gardens, London.

12491. **Improvements for administering electricity to animals or human beings.** Edmond Savary d'Odiardi and Eva Savary d'Odiardi, 43, Cornwall gardens, London.

12492. **Improvements in liquid electrodes.** Edmond Savary d'Odiardi and Eva Savary d'Odiardi, 43, Cornwall gardens, London.

12793. **Improvements for charging vapours for inhaling purposes or others with electricity.** Edmond Savary d'Odiardi and Eva Savary d'Odiardi, 43, Cornwall gardens, London.

12507. **Improvements in the construction of galvanic cells.** Cæsar Vogt, 38, Chancery lane, London.

12514. **Improvements in safety fenders or lifeguards for electric street railway carriage and other vehicles.** Edwin Rochester, 45, Southampton buildings, Chancery lane, London. (Complete specification.)

12516. **An improved loud-speaking telephone and circuits for same.** Alfred Graham, 1, Gresham buildings, Guildhall, London.

JUNE 27.

12577. **Underground electric system.** John Alexander Kennedy McGregor, 43, Lincoln's-inn-fields, London. (Complete specification.)

12612. **Improvements in the construction of electric fittings.** Edward Priddle, Newington Priddle, and Co., Limited, 1, Queen Victoria-street, London.

12625. **Improvements in and connected with the purification of sewage by electrolysis, producing electricity as a by-product.** Walter Walker, 34, Lorne-gardens, London. (Complete specification.)

JUNE 28.

12662. **Improvements in electrolysis.** Emile Andreoli, 18, Somerleyton road, Brixton, London. (Complete specification.)

12700. **An improved electric push or contact-maker.** Robert Beveridge, 18, Buckingham street, Strand, London.

12702. **Improvements in electric cables.** George Cotton Melhuish Hardingham, 191, Fleet street, London. (The firm of Felten and Guilleaume, Germany.)

JUNE 29.

12785. **Improvements in switches for electric currents.** Anthony George New and Arthur James Mayne, 12, Palace-chambers, Westminster, London.

12786. **Improvements in self-regulating mechanisms for electric arc lamps.** Anthony George New and Arthur James Mayne, 12, Palace-chambers, Westminster, London.

12787. **Improvements in the manufacture of coke or carbon for electrical purposes.** John Laskey Dobell, Charles Percy Shrewsbury, Frank Lawrence Marshall, and John Cooper, 57, Chancery lane, London.

JUNE 30.

12806. **Improvements in electrical switches.** Frederick Adolf Timm, 18, Fulham place, Paddington, London. (Complete specification.)

12850. **A counter of electricity.** Francois Alexandre Brocq, 28, Southampton buildings, Chancery lane, London.

12852. **Improvements in or relating to the distribution and supply of energy in electric current circuits.** William Lowrie, 433, Strand, London.

12857. **Improvements in and connected with tanks for the electrical decomposition of chloride of sodium or potassium in solution.** James Charles Richardson, 6, Bream's-buildings, London.

12864. **Improvements in electric locomotives and vehicles.** Joseph Frederick Wilks Featherstonhaugh, 46, Lincoln's-inn-fields, London.

12866. **An improved electric lighter.** Reginald Walter Barker, Monument chambers, King William street, London. (Max Sommer and Bernhard Troop, United States.)

12870. **Magnetic fastening for safety lamps and the like.** Heinrich Freise, 54, Fleet street, London. (Complete specification.)

JULY 1.

12919. **Electrical arc lamps.** William Jeffrey, 39, Beckton road, Barking road, London.

SPECIFICATIONS PUBLISHED.

1885.

12681. **Arc lamps.** Brockie and Pell. (Second edition.)

1891.

22304. **Electric signalling.** Thompson. (Second edition.)

NOTES.

Technical School.—The foundation stone of the new technical school buildings at Darwen was laid last Saturday by Mr. C. P. Huntingdon, M.P.

Ostend.—Tenders are invited by the Administration Communale of Ostend for the lighting of the town by electricity. The adjudication will take place on September 15 next.

Cannes.—While Nice is to have a station shortly, Cannes has already obtained hers, and 7,000 lamps are glowing. In a couple of years the total number will rise, it is thought, to 20,000.

Paris.—The Parisian Compressed Air Company are intending to instal at the rue Saint-Roch an important central station, using the five-wire system in conjunction with Tudor accumulators.

"The Electrical Worker."—A copy has reached us of the *Electrical Worker*, published at St. Louis, the organ of the National Brotherhood of Electrical Workers of America. Says the prospectus: "It reaches the men who do the work."

Balloon-Lighting.—The balloon "Humboldt," which recently came to grief, has been replaced by another by the German Aerial Navigation Department. This balloon is electrically lighted at night, and experiments in electric signalling are about to be made on its journeys, commencing generally at 11 p.m.

Electrical Treatment of Stricture. — Mr. C. Mansell Moulin, surgeon to the London Hospital, has an article on the application of weak electric currents to the cure of stricture in the *Lancet* (8th inst.). He gives cases, and, although considering there is some field for electricity, is not very enthusiastic in its favour.

Appointment at Sheffield.—A teacher of mechanical and electrical engineering subjects, able to take charge of large classes in machine construction and drawing, practical plane and solid geometry, and to direct workshops in wood and metal, is wanted by the Sheffield School Board. The Board state their preference for a Whitworth scholar.

Water Power in Switzerland.—The Conseils Communaux of Locle and of Chaux de Fonds, Neuchâtel, Switzerland, have opened a competition for the utilisation of a part of the water power at Reusse. Particulars may be obtained of the Direction des Eaux et du Gaz, Chaux de Fonds, Switzerland, and tenders will be received until August 31.

"School of Magnetism."—The "Société Magnetique de France" (23, rue Saint-Merri) has organised a practical school of magnetism, with a two years' course under professors to study physiology, animal magnetism, occultism, hypnotism, and so forth. The first courses will be given by Drs. Vigouroux and Rouxel, with experimental clinical demonstrations.

Tax on Electricity.—A curious case has arisen at Vigan, France. M. Carrière there has a right to charge *octroi* on goods entering, and amongst other commodities are candles and petroleum. Now electricity is installed in the town, however, his receipts on this score are diminished, and on plaint he has actually been awarded 400f. damages to his interests. Another injustice to electric light!

Electric Light Lantern.—A convenient electric light lantern (made by Colt, Beekman street, New York) is illustrated in the *Scientific American*, June 17. It has bellows, front and objective support that are removable, allowing the use of microscope or other scientific instrument. The adjustment of the carbons is very easy—no more difficult than the occasional turning of the lime in ordinary lanterns.

Altona.—The *Elektrotechnische Zeitschrift* for July 7 contains a well-illustrated long descriptive article, by Herr Uppenborn, on the lighting of Altona by Messrs. Schuckert. The plans, details, and views give a good idea of the best modern continental practice in central station work. The system is direct current with accumulators.

Electricity in Quarrying.—At the quarries of the Société Anonyme des Carrières du Hainaut at Soignies, Belgium, the Compagnie Continentale d'Electricité de Bruxelles has installed a generating dynamo, which operates two motors and lights 100 16-c.p. lamps and eight 12-ampere arc lamps. One of the motors drives the pumps, and the other actuates a windlass which is used for hauling the blocks out of the quarry.

The Single-Trolley System.—The single-trolley system has already made fair progress in Germany at Halle, Bremen, and Gera. A new line on the method has just been started at Remscheid, and work is rapidly being advanced at Essen. We have already referred to the decision to adopt this system in several French towns, and at the moment negotiations are proceeding for the establishment of a line at Etaples, in the Pas de Calais.

A Kindly Recognition.—We are informed that on the successful completion of the Royal Hotel installation, Mr. Collings, Messrs. Siemens Bros. and Co.'s engineer in charge of the works, was presented by Sir Polydore de Keyser with a handsome and costly gold non-magnetic watch. The value of this gift was greatly enhanced by the kindly words with which Sir Polydore accompanied the presentation. We think that an act so graceful is worthy of record.

Transforming Continuous to Alternating.—M. Felix Lucas (in *L'Electricien*, 8th inst.) describes at length, giving diagrams and sections, his apparatus for changing a continuous current, as from accumulators, into alternating currents of any desired frequency. A model machine has been made by MM. Sautter, Harlé, et Cie. A current of 1,000 amperes at 20,000 alternations per second, says the author, can be obtained with a wheel of one metre diameter with 20 brushes.

Nice.—The town of Nice is to be lighted electrically soon. At first it was thought to utilise the falls of Vesubia, but it is decided to have a steam station in the centre of the town. The Alsacian Society have the contract, but there are several large houses (a hint to the wise) who would nevertheless have their own installations if proper overtures were made. The three-wire system will be adopted. It would be interesting, by the way, to learn how far continental companies pay for their use of three-wire patent.

Friction Clutch.—A new elastic friction clutch, invented by M. Brancher, is illustrated in the *Revue Industrielle* (July 8). In this clutch the transmission from one shaft to another is effected by an elastic connection composed of bands of steel covered with leather, which make two and a half turns round a cylindrical drum. The connection is brought about by a cone under control of a hand-screw, and the second shaft takes up the rotation gradually from 0 to speeds of 100, 200, 500 revolutions. It has been applied to powers of 100 h.p., and has proved very practical.

Colliery Explosions.—At a general meeting of the South Wales Colliery Officials' Association, held at Pontypridd, last Saturday, under the presidency of Mr. Thomas, manager of the Ynyshir Colliery, a paper was read by Mr. W. Thomas, of the Ynyshir Collieries, suggesting means of avoiding suffocation in cases of fire in collieries. During the discussion Mr. Meredith mentioned an instance

where an electric signalling battery worked direct from the dynamo, and falling with some rubbish, caused a small fire in the colliery. The question will be further discussed at the next meeting.

"Commerce."—The somewhat humdrum official, not to say, dry *Chamber of Commerce Journal* becomes this week incorporated with *Commerce*, an illustrated weekly, price 6d. The size of *Truth*, with a coloured cover, full of interesting illustrations, an interview with Mr. Henry Norman, chatty articles, description of the Manchester Canal, not forgetting more serious financial and commercial articles and notes, the new journal makes a fair bid for success and brightness at a bound. The list of commercial situations vacant and wanted is continued. It is a paper to which those who deal with foreign countries should not hesitate to subscribe. It is published at Talbot House, Arundel-street.

Electrical Communication with Lighthouses.—The Royal Commission on Electrical Communication with Lighthouses and Lightships began on Tuesday their inspection of lighthouses and lightships on the south and east coasts of Ireland and the Isle of Man. They intend to visit Bangor, Belfast Lough, to-day, the 14th inst., after inspecting the South Rock and Skull Martin light vessels from H.M.S. "Enchantress," and they intend also to anchor in Lough Foyle on the 17th inst. for the purpose of visiting Rathlin Island, Innishowen, and the Inishtrahull lighthouses. Mr. Mulholland, M.P., who is a member of the Royal Commission, has paired with Mr. Munrow Ferguson, M.P., for the period of the cruise.

Electrolysis of Pipes.—Mr. C. H. Morse, inspector of wires at Cambridge, Mass., in a recent paper before the New England Waterworks Company, stated that in his town, after the electric street railway had been started, "lead pipes disappeared in a short space of time—some even in six to eight weeks." Rustless iron was tried, but it rusted away. The loss was not confined to pipes, but the railway company lost 25 out of their 500 volts. Where the volts and pipes got mixed, there was often little but mould left after a time. When they reversed the poles they hurt the gas company, and set up electrolytic action in the gas-pipes. Mr. Morse waxes very serious over the difficulty, and sees no way out but putting overhead returns.

Variable Meter.—An electric meter is described by the *Bulletin International*, which is arranged so that during one portion of the day it registers less than at others. This is to allow the use of current during the time of light load at less cost for motors and cooking. This result is obtained by allowing the registration of the meter to be affected, first by one train of wheels and then by another, the change being made by a wheel revolving once in 24 hours. The idea seems noteworthy, but it is doubtful if the Board of Trade would allow this false registration. The double-registration meter might register on two sets of dials for day and night service, the price to be lower in the former per supply unit. Companies on the look out for equalisation of load should look into this question.

Light and Frequency Phenomena.—Dr. Samuel Wilks has a letter in the *Lancet* (July 1) discussing Mr. Nikola Tesla's question as to whether it will ever be possible to analyse the condition of the retina when an image is evoked by thought or reflex action, so that a clear idea of its state might be obtained. "Although the direct influence of the nerve centres on the various tissues of the body must be admitted," says Dr. Wilks, "it is proceeding to a very great length to say with Mr. Tesla that the organs of the senses can be *affected* from within." This seems, he says, like a total contradiction of the teachings of physiology. "Mr. Tesla's suggestions," he adds, "are of great importance, but cannot be accepted, as they tend to break down our long-cherished views regarding our organisation and the operation of our senses."

Electric Light Accident at Rome.—On the Piazza Quirinal, in Rome, last Friday night, two electric light lampmen lost their lives through a piece of almost incredible carelessness. One of the large lamps opposite the palace suddenly went out. The lampman belonging to the district brought a ladder and ascended, but had scarcely touched the carbon when he fell to the ground from a height of 16ft. His companion, believing him to be seized with sudden illness, went up in his place, but almost immediately fell. Both men had neglected to use the simple mechanism at the base of the lamppost which interrupts the electric current when any repairs or manipulation are necessary. The men were conveyed to the hospital, but they were both dead. The engineer of the society states, says the *Standard* correspondent, that the orders given to the men as to the use of the switch are most rigorous, and the men are daily exercised in its use. The King telephoned to the hospital an enquiry about the unfortunate men.

Underground Telegraphs in Germany.—Soon after the great war of 1870 the military authorities decided on connecting the great fortresses of the empire by underground cables. The ease, says *Kuhlow*, with which the German lancers managed in France to destroy the enemy's telegraphic communications miles and miles ahead of the German vanguard was a lesson not to be forgotten at home; that very important instrument in modern warfare—the telegraph—was no longer to be entrusted to overground wires and poles at the mercy of any plucky horseman, but to a substantial cable sunk deep into the ground. In this way Metz and Strasburg became connected with each other first, and then with Mayence and Cologne, with Berlin and Graudenz at the other end of the empire. After the great fortresses there came the turn of the capitals, the seaports, and the most important commercial and industrial cities—all of which are now connected by subterranean cables, hid deep in the earth, or bedded in the solid rock, or resting on the bottom of rivers and lakes, well secured against the frequent interruptions by storms and floods and snows, to which overground lines are exposed.

Sir Francis Ronalds.—Honour to the pioneers in the vast field of science! says the *Daily News*. Mr. John Sime has just published at the Chiswick Press in pamphlet form a very interesting memoir of Sir Francis Ronalds, with autotype fac-simile of a portrait of this father of electric communication. Twenty years before Wheatstone and Cooke or Morse had patented their improvements in the telegraph, indeed while the first two were respectively lads of 12 and 14 years of age, Ronalds had sent messages over eight miles of overhead wires of his own construction, and had laid and worked a serviceable underground line of telegraph of sufficient length to demonstrate the practicability of communication by telegraph between long distances. Details of his overhead telegraph wires were published by him in 1823. Ronalds's residence at Hammersmith, where these experiments were carried out, is the house now, and for long past, occupied by Mr. William Morris, the poet, who has caused a tablet to be placed on the wall bearing the inscription, "The first electric telegraph, eight miles long, was constructed here in 1816 by Sir Francis Ronalds, F.R.S., etc."

Five-Wire Power Distribution.—MM. Zweifel and Hoffmann have elaborated for the town of Mulhouse (*Revue Industrielle*, July 1 and 8) a plan for distributing electric energy for motor purposes at 1,500 volts on the three and

five wire principle. Up to 50 h.p. the motors will be on the 750-volt branches, and above this on the 1,500-volt outside mains. Below 5 h.p. they can be on 110-volt lighting mains, which will be reduced by continuous-current transformers. With transformation the efficiency will be $\cdot 95 \times \cdot 95 \times \cdot 90 \times 80 = 65$ per cent., and without transformation (large motors) $\cdot 95 \times 95 \times \cdot 93 = 83 \cdot 9$ per cent. The following table is given :

Motors h.p.	Speed in revolutions.	Efficiency per cent.	Price (francs) per h.p. with accessories.
$2\frac{1}{2}$ to 5	1,500 to 1,000	80 to 83	500 to 350
5 to 25	1,000 to 750	83 to 90	350 to 150
25 to 50	750 to 600	90 to 92	150 to 120
50 to 100	600 to 450	92 to 93	120 to 110
100 to 250	450 to 250	93 to 94	110
250 to 500	250 to 100	94	110

The price will include foundations and leads ; the arrangements for excitation make the smaller sizes comparatively high.

Auto-Conduction.—M. d'Arsonval, at the Académie des Sciences, July 3, proposed a new method of electrification of the body, which he terms "auto-conduction." The currents which circulate in the body of a patient are not led to his person by conducting wires, but take place within the tissues themselves, which act as closed induction circuits. These currents may attain considerable strength as they produce no pain nor any conscious phenomena to the person experimented upon. They nevertheless act energetically on the vitality of the tissues. M. d'Arsonval obtains this result by placing the subject either entirely or in part within an oscillating magnetic field of very high frequency. Upon a cylinder of some insulating material is wound in one or two layers a carefully-insulated electric cable. This constitutes a kind of solenoid, within which the subject is placed ; it is traversed by the discharge of a condenser, arranged in a special manner, so that the coil is energised by a current of a frequency of 200,000. He bends the arm so as to form a circle, and closes the circuit while holding a lamp in his hand, which lights up without causing any sensation. This mode of electrification of the human body is stated to produce some curious effects.

University Laboratories.—The formal opening of the new laboratory of mechanical and electrical engineering at the College of Pennsylvania, is made the occasion of an illustrated article by Edward T. Child in the *Electrical World* descriptive of this laboratory. In the boiler-house are seven large boilers arranged for testing. It has a chimney 150ft. high, and a fan for forced draught. The laboratory proper is four storeys high of mill construction. On the first floor are engine and mechanical laboratories, with three 100-h.p. (Westinghouse, Armington-Sims, and Porter-Allen) engines driving Brush, Edison, and Thomson-Houston dynamos, and there are half-a-dozen other smaller engines. The second floor contains library, reading-rooms, classrooms, and testing laboratories. On the third floor are drawing-rooms, classrooms, and a more delicate electrical laboratory. The fourth floor contains blue-print and model rooms. Pattern-making is taught, and the installation makes a small central station in itself, while the real central station in the town is affiliated. Specialists give lectures on wiring, specifications, and business law. The whole thing, indeed, seems most thoroughly done for the turning out of well-trained practical electrical engineers.

Popular Electricity.—The *Glasgow Herald* concludes a useful series of five popular articles on "Electricity as an Illuminant" last Saturday. The last article deals with storage batteries, electrical units, and prices. The writer thinks the invention of an efficient arc light of much smaller candle-power than any now in use would be a most useful discovery. He should be recommended to try the "Midget" arc lamp, certainly one of the best of the smaller lamps. It burns well with five amperes at 35 volts, and could be run three in series on a 110 volt circuit. The writer concludes : "There is undoubtedly a great future for electricity as an illuminant. Men of the highest capacity are engaged in the industry. The past few years have shown that the quarterly bill for electricity need not exceed that for gas ; indeed as time goes on, and the new illuminant is in general use, its cost to the consumer will be decidedly less—a result the attainment of which will be greatly helped by the use of electric energy for purposes other than lighting, and at a time of the day when light is not in requisition. It is estimated that in London at the present time there are 800,000 incandescent lamps in use. But the best proof of the certain onward march of electricity as an illuminant is seen in the fact that wherever it is introduced the demands for its extension are continuous and ever increasing." Those who wish to have a full popular *résumé* of electric lighting for propagandist purposes might do worse than send round copies of these articles, which of course can be obtained at a penny per article.

Electricity in Mining.—Germany was, we believe, the first country in Europe to introduce electric power in mining operations, this being at Stassfurt salt mines several years ago ; but since then very little progress has been made there. At the Mining Exhibition, however, now being held at Gelsenkirchen—the centre of the Ruhr or Rhenish-Westphalian coal district—and where more than 200 firms are represented, electricity for lighting and motive-power purposes has been made to occupy a prominent position. Various dynamos are shown in operation by Schuckert and Co., of Nurnberg; and the Deutz Gas-Engine Works exhibit, among others, a 16 h.p. twin gas engine driving various motors of the General Electricity Company. The buildings are, of course, lighted by electricity, and from the machinery hall two installations of electrical transmission of power a distance of 330ft. are in operation : one is by Jorissen and Co., of Dusseldorf, with a Lahmeyer dynamo and motor, and the other by C. W. Hasenclever and Sons, of Dusseldorf, with Schuckert dynamo and motor. Ventilating fans are naturally in prominence, but there does not appear to be any application of electricity to pumping purposes. As regards miners' electric safety lamps, C. Pollak and Co., of Frankfort, the Accumulatorenfabrik Hagen, M. Vorster, of Jena, and F. Feldhaus, of Cologne, are the exhibitors. Wire ropes and cables are ably represented by Messrs. Felten and Guilleaume, of Mulheim-on-the-Rhine, Becker and Co., of Schalke, H. Grillo, of Dusseldorf, and H. Puth, of Blankenstein. In the grounds, a mining electric locomotive by Schuckert and Co. hauls two waggons.

Municipal Telephones for Glasgow.—The following memorandum drawn up by Council or Starke was submitted to the Special Committee of the Glasgow Town Council on Monday : "A cheap and efficient telephone service is now an absolute necessity in large business centres, and the larger the centre the greater the need. In Glasgow it may be said to be indispensable ; nevertheless our present service is neither cheap nor efficient. The annual rent is £10 and upwards per user, whereas in Canada on some exchanges the rates are as low as £1 per annum ; in Holland they range from £2. 10s. to £6 ; in Gothenburg from £3. 6s. to £6. 10s., according to the service given, and in Melbourne the charge is £6. In Stockholm, which has two very complete telephone systems, one being in the hands of the State authorities, the charge is only £4. 8s. 11d. per annum, which covers

free conversation within a radius of nearly 40 miles, and the service is a very superior one. It is interesting to note that Stockholm, with its population of 228,000, has upwards of 8,000 users, while Glasgow, with a population of 814,000, has not more than 3,500—there being one subscriber to every 27 inhabitants in Stockholm, while there is only one to every 230 in Glasgow. In order to give a cheap and efficient service two conditions must be fulfilled—first, a complete twin-wire system, combined with the most modern appliance, must be provided; and second, the strictest economy must be exercised in the expenditure of capital, so that rent may be chargeable only on the cost of the plant actually needed per user in addition to the usual working expenses. In small places, where there are few wires near one another, and where there is consequently little risk of contact and induction, a single wire is sufficient, the earth serving for the return current; but large cities cannot be efficiently served without a double wire or metallic circuit, because of the continual noises and interruptions going on. These are picked up if the earth is used for the return, whereas they are not heard at all over a twin wire. The electricians of the Post Office and the leading officials of the Telephone Company are at one on this point, as proved by their evidence before the Select Committee on the Telephone Bill on June 15, 1892; indeed, it is understood that the Post Office declines to connect any but twin wires with the new system of trunk wires it is erecting throughout the country. The amenity of the city is being destroyed by the network of overhead wires running in all directions, which need not exist, and which are a source of no inconsiderable danger. In order that the Corporation may take the matter in hand, all that is required is to apply to the Postmaster-General for a license, and, after obtaining it, to commence operations. Glasgow has already its electrical department, with conduits laid and to be be laid for lighting purposes, the conduits, according to the opinion of the engineers of the Post Office, being quite suitable for telephone underground wires. It can therefore give a perfect telephone service to the citizens much better and more cheaply than any company. Reliable estimates in detail have been prepared, showing that for a capital of about £15 per user the latest and best system can be laid down in Glasgow within the municipal radius. On this basis a thoroughly efficient service could be given at an annual charge of about £5 per user, or possibly less. £50,000 would be ample capital for a start, and if, as is likely, the 3,000 to 4,000 probable applicants for whom this would provide should be greatly exceeded, the necessary capital for additional users would be relatively less." After consideration of the memorandum, the committee unanimously agreed to recommend the Town Council to apply to the Postmaster-General for the necessary license to establish a telephone system in Glasgow. This recommendation will be considered by the Town Council at their next meeting.

High Temperatures.—An electrical process for obtaining temperatures very much higher than those at present realisable is spoken of by MM. E. Lagrange and Paul Hoho in the *Bulletin* de la Société Belge d'Electriciens. The authors talk airily, though not without restrictions, of temperatures of 800,000deg. C; and without going further than to say there is a suggestion of something realisable, it may be still desirable to give an idea of their statements. The voltaic arc gives a temperature of some 3,500deg. C. The authors studied, in a paper presented last year to the Académie, a luminous and calorific phenomenon which takes place in certain liquid conductors, at the contact between these liquids and one of the electrodes under certain conditions. This gives rise to very high temperature. The peculiar characteristic of the phenomenon is the formation of a gaseous sheath of high resistance around the electrodes. The energy of the current is transformed into heat, and as it is at the actual contact of sheath and electrode that the resistance is localised, the most intense heat is just at the surface of the electrode. The quantity of heat given off per square centimetre of the surface of the electrode is equal, per second, to the product $\frac{E\,I}{4{,}200\,S}$, where E is the potential between liquid and electrode, I the current, and S the surface immersed expressed in cm^2. In the paper to the Académie it was stated that the luminous sheath formed after the difference of potential had risen to a certain maximum variable with the nature and conductivity of the liquid. The current density increases with the conductivity, but not proportionally. With a solution of 55·5 per cent. by weight of sulphuric acid, at 75 volts the current density is 12·5 amperes per square centimetre, which gives as energy expended per second 957·5 watt-seconds, or 0·223 calorie. At increasingly higher voltages the current increases, but less quickly than the E.M.F.; it seems to increase very nearly as the square root only. If the difference of potential is 625 volts, the current will be three times its first value, or 37·5 amperes, and the quantity of heat given off 27 times greater, or $0{\cdot}223 \times 27 = 5{\cdot}921$ calories per second per square centimetre. Now this current of 37·5 amperes at 625 volts (the authors point out) already produces a temperature considerably higher than that of the arc of equal surface—that is, of the source of the highest present known temperatures. But, further, it can be demonstrated to what heights of temperature a body serving as electrode could be carried, under conditions easily realisable. Take as electrode a plate of graphite 1mm. thick and 1cm. square, and immerse it in a 10 per cent. solution of sulphuric acid at a difference of potential of 1,875 volts. In these conditions the current is 62·5 amperes per cm^2, and the total current issuing from the two faces and the lateral edges 114·75 amperes. The electric energy transformed in heat is, per second, $114{\cdot}75 \times 1{,}875 = 271{,}406$ watt-seconds, or 64·62 calories. The mass of the graphite plate is 0·00015 kilogramme, taking 1·5 as density of graphite. The specific heat being taken as 0·52 calorie, then the 64·62 calories per second is the heat required to raise the plate to the temperature of $\frac{64{\cdot}62}{0{\cdot}52 \times 0{\cdot}00015} = 828{,}460$deg. C.! This calculation has evidently no physical signification—it supposes the state of the graphite does not vary, and the specific heat remains constant; it leaves out of account radiation and conduction. Nevertheless, the 64 calories are given off at the surface, and in one second: and it is certain that at the end of a second the plate will have attained, especially at the superficial layer, a temperature inconceivably greater than any realised by present methods. Nor is this all, for voltages of 3,000 to 5,000 are at disposal if required. The authors conclude: "The following facts are to be observed: (1) When a current traverses an electrolyte, the latter is decomposed and the elements thus liberated are deposited on the electrodes in nascent state; (2) at the contact of one of these electrodes with the electrolyte there takes place the calorific action above set forth. At the contact with the electrode and the electrolyte, therefore, are united two actions—an electrical action and an excessively intense calorific action which are of a nature, under certain conditions, to enable chemical action to take place with very special energy. On this account we think it well to draw the attention of chemists to this physical phenomenon."

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

ARC LIGHTING.

(*Continued from page 9.*)

Diffusion of Light.—A number of people complain that the electric light, whether in the form of an arc lamp or incandescent lamp, is irritating and painful to the eye when looking at it. When the lamps are entirely uncovered, and the eyes are allowed to rest on the naked arc or filament, as the case may be, the above troublesome effect is not to be wondered at. It must be remembered that the light is of very great intensity, irrespective of the quantity of light, and that being so, concentrated rays require dispersing or diffusing. Daylight is light in the most perfect diffused state, and the source, the sun, need not be visible to our eyes at all. Moonlight, which is borrowed sunlight, is a beautifully softened light, although the shadows are strong. Contrast these with our methods of artificial lighting. We produce light by sprinkling about a greater or smaller number of points or concentrated sources of light, the light being intense close by, and diminishing rapidly at a distance. If we were to break up these points of light into a countless number of infinitely small sources, placed close together, we should then obtain a diffused effect. An ideal illumination of a room would be to have the whole of the ceiling to throw off a subdued and diffused light, thus converting the irritating and unpleasant points of light into large luminous surfaces.

A most simple example is to compare an incandescent lamp and a gas jet. It is much easier to look at the latter than the former. Why? Because the electric lamp gives its light from off a slender thread of carbon raised by intense heat to a white hot state. The luminous surface is here extremely small, but extremely intense. On the other hand, the light from a gas jet is given off from a broad surface, and the light is not intense. The quantity of light in each case is about the same: the former being a concentrated light, while the latter is less concentrated, and consequently more diffused.

We have not made one jot further progress in the art of illumination since the days of the ancients, when perfumed oils were burnt in their vessels; and so far as gas is concerned, we have taken a retrograde step, for whereas the oil vessels were costly articles and the burning of good oils produces a pleasant and soft light, the ugliness of gas brackets and the foulness of the gas burnt is universally known.

The intensity of the light of the electric arc is probably greater than any other artificial source of light. After gazing at a naked arc for a few seconds the eyes will be almost blinded, just as if one had looked at the sun. The temperature of the crater has been variably estimated, but 3,000deg. to 6,000deg. C. is near the right number. The light rays that are emitted from the glowing crater are only about 10 per cent. of the total rays, the other 90 per cent. being invisible, or dark heat rays, and yet this source of light gives many more light rays than other forms of artificial illumination; for example, a gas flame gives only from 3 to 4 per cent.

Arc lamps are now rarely run without having some kind of globe over them, except when used for lighting up large open spaces belonging more or less to private concerns—like dockyards, works, goods-yards, etc., where appearance is not considered provided they get the light. There are several different kind of globes used on arc lamps, each of which absorbs so much of the light: all of them help to diffuse the light and to lessen the shadows. By using very thick porcelain globes a great amount of light is absorbed or cut off, but against this disadvantage must be put the fact that the light available is well diffused and softened down, thus reducing the intensity and preventing deep shadows. The following figures give the probable amount of light that is cut off by different globes:

TABULATION 21.

Clear glass	10 to 20 per cent. loss
Thin ground glass	20 to 30 ,, ,,
Thick ground glass	30 to 40 ,, ,,
Thin opal glass	40 to 50 ,, ,,
Thick opal glass	50 to 60 ,, ,,

So that the light can be toned down to any degree by using a suitable globe.

The City of London Electric Light Company use a lantern having panes of ribbed prismatic glass, whereby the arc light is greatly magnified and softened down, so that the light rays are well diffused.

The value of a light for any particular purpose depends upon its composite rays, and the superiority of the arc light for illuminating purposes can easily be proved to be much beyond oil, gas, or any other artificial source. We will, therefore, analyse different kinds of light, and briefly sum up their composition of rays, taking the sun as the standard.

The light from the sun is composed of a number of homogeneous colours mixed together in a certain proportion, and forming what is called a "spectrum." The light given by the spectrum of the sun is colourless, and is called white light.

The colour of any substance or matter is regulated by the kind of rays which it *absorbs* from the light by which it is illuminated; for instance, a white substance, like snow or anything with a white surface, does not *absorb* any of the rays of the sun, but *reflects* them all back again, hence the snow appears colourless or white in daylight, because the light of the sun is white. A black surface, on the contrary, like coal, absorbs all the rays of sunlight, and so appears colourless or black. So when all the sun's rays are visible we have no colour, or a white appearance, and when none of the sun's rays are visible we have also no colour, or a black appearance. A substance having a yellow appearance signifies that all the sun's rays are absorbed except the yellow rays, and these are reflected back, thus giving the yellow tint. After this preliminary explanation respecting colours, we can now realise that a substance may present a different or modified colour when it is looked at in the light given from some artificial source.

The light given by gas, oil, or candles contains all the colours that the sun contains, but they are mixed in a different proportion; this is the same with the light of the electric arc. The tabulation below shows how the various coloured rays mentioned are distributed in the three illuminants—the sun, gaslight, and the electric arc.

The electric arc light is much nearer the light of the sun than any other artificial light; consequently, the natural colours of things are seen better by the electric light than by gaslight. Gaslight is particularly rich in the *red* or *heat* rays, while the electric arc is particularly rich in the *violet* or *chemical* or *actinic* rays.

The arc light is invaluable when colours require matching, because, with the exception of a very few shades, all the colours and shades known to us can be seen just as they would be in the light of the sun or daylight. A certain eminent silk firm made a thorough trial of the value of the electric arc in their mills, and they found that out of about 650 different colours and shades, there were only seven that could not be matched in the light of the electric arc. The writer cannot recollect what they were, but bronze was one of them.

TABULATION 22.—Colours of Rays.

Degree.	Yellow.	Red.	Violet.	Blue.	Green.
Rich	Gas.	Gas.	Arc.	Arc.	Gas.
Poor	Arc.	Arc.	Sun.	Sun.	Arc.
Very poor.	Sun.	Sun.	Gas.	Gas.	Sun.

Everybody knows how impossible it is to distinguish between shades of blue and green in gaslight. The above tabulation explains the reason why, there gas is shown to be very poor in blue rays, but very rich in green rays. A green substance reflects a small number of blue rays in addition to the green rays, and a blue substance reflects both blue and green rays. Therefore when a blue cloth is inspected by gaslight it will appear more or less greenish, because gaslight has plenty of green rays, but very few blue. On account of the great number of violet rays present in the arc light, the arc lamp is of great use in photographic work, such as the printing of negatives, etc.

(*To be continued.*)

ELECTRICAL MAINS AND METHODS OF LAYING.*

BY C. H. W. BIGGS, M.I.E.E.

Let me at once say that this paper pretends to nothing more than a kind of preliminary, dealing generally and elementarily with many subjects that, to be thoroughly discussed, would each need a paper of an elaborate character to itself. The view taken is that municipal engineers have not, as a rule, made a special study of electrical matters, yet, in the ordinary course of things, they may be called upon more or less suddenly to deal with these questions. Generally, so far as my experience goes, those who try to throw a little light on the subject talk too much about dynamos and the paraphernalia of the generating stations, and too little about the expensive part of the plant required for distribution.

The members of this institution are responsible for the condition of the roads, streets, and pavements of the kingdom—hence, whatever interferes with these must be considered of interest; but in addition to the mere maintenance of streets, one of the most onerous duties of the borough engineer is the giving advice to his council in matters electrical. As one who is doubly interested in these matters—on the one hand from the municipal, and on the other from the electrical standpoint—I am naturally anxious to elicit information as to the exact conditions each party requires fulfilled. If the municipality—as I hold it ought to do—undertakes the production and distribution of the means to provide for the artificial illumination of the district over which it holds sway, it will have full and complete control of the generating stations and the system of distribution.

With the generation of electrical energy I have little to do in this paper, except to assume that it will be generated either on the high or the low pressure system. If generated on the high-pressure system, it may be either to give continuous or alternating currents. If the alternating system is adopted, most probably a different kind of main will be used than if on the continuous current. The reason of this may be explained. According to the researches of Lord Kelvin, Oliver Heaviside, and others, the phenomenon which we call current in alternate-current work affects only the external part of the conductor. The slower the alternations, the greater the sectional depth of the conductor that takes part in carrying the current; the more rapid the alternations, the less the depth of conductor so acting. Hence the view has arisen of late years that the conductor is more of a directrix than anything, and given sufficiently rapid alternations, the action is a mere surface action between the dielectric and the conductor. Thus the conductors for alternate currents are sometimes hollow metallic tubes—in fact, copper tubes—in order to obtain a large surface area. Mr. Ferranti was, I think, the first to arrange the outgoing and the incoming tubes concentrically in his mains from the Deptford generating station to the Charing Cross and other districts supplied from Deptford.

It will be best to avoid as far as possible the discussion of purely electrical matters, except so far as they bear directly upon the object of this paper. Assume, then, that we wish to generate a given quantity of electrical energy and utilise it at a certain point. What difference will it make to our mains if it is generated under high pressure or under low pressure? The heat developed in a conductor is given by the well-known formula C^2R—"current squared" × "resistance"; from which it is seen that a small increase of current may mean a considerable increase of heat. We neither want our mains melted, nor, in fact, made hot, we want the heat evolved at the lamps, for elsewhere it means loss. The heating of the conductor increases the loss in another way, as it also increases the copper resistance. By generating under high pressure we obtain our quantum of electrical energy with little current, the energy being represented by the product of "current" × "pressure." In the formula $C\,E$, C = current; E = pressure. Increasing the pressure means decreasing the current, and a small current means a small conductor, which, as copper is generally used, means a saving of copper. On the other hand, the current will traverse any road it can find, and it goes over these roads in quantities inversely to the resistance to its progress these roads offer. In our operations we want it to go over a particular road, and not meander away in other direction, being thereby lost for our work, not to mention the danger arising to both life and property from its being where it is not wanted. With high pressure, then, we have to be exceedingly careful as to the insulation of the conductor. Hence, while we gain by saving copper, we lose something by having to use more costly insulation. Mains must be constructed so as to avoid loss from heating and loss from leakage. There is still another point to which attention must be directed. If we use our electrical energy for lighting purposes, we want the current to be as large as possible at the point of use, because its value for the object in view varies as its square. The electrical energy may be generated at a high pressure and a small current, but it is used at a lower pressure with larger current. If our apparatus were perfect we might convert 2,000 units of pressure (called volts) × 2 units of current (called amperes) into the equivalent energy: 100 volts pressure × 40 amperes current. The piece of apparatus for such conversion is called a transformer. Some of the advocates for high pressure would supply a transformer to every house, others prefer a transformer to a group of houses. Whichever plan be adopted, the cost of transformers has to be considered. This extra piece of apparatus must also add to the cost of maintenance. Further, unless the transformer be absolutely cut out of the circuit when it is not required in the production of light, it is constantly using up more or less current in order to keep the iron core magnetised, which is another source of loss.

Summarising, high pressure requires less copper in the mains, but more and better insulation. It requires the use of transformers, either in every house or at sub-stations for a group of houses. These transformers have to be paid for initially and have to be maintained; they also lead to a smaller or greater constant loss of current. The great advantage of high pressure is in enabling the central station to be erected in places where land costs less than where the position is more rigidly defined, where fuel and water are more cheaply obtained, and other similar advantages. Low-pressure working requires the central station to be at hand (according to the calculations of Messrs. Crompton and Wright, the distance must not exceed from 2,000 to 2,500 yards), and it needs more copper in the conductors. As generally adopted, low pressure (the limit of which is 500 volts) also requires transforming, but in a different way to that adopted with high pressure. This naturally leads to a few words about the

Three Wire System.—If we have a dynamo generating at 100 volts pressure, the pressure ordinarily required by the lamps, the current can be used at that pressure without transformation. There must be a complete conductive circuit (main) from one terminal of the dynamo to the other, and usually the lamps are placed across the mains. Fig. 1 shows this. A and B

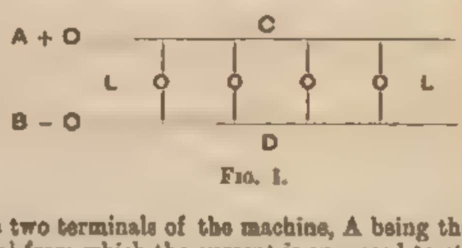

FIG. 1.

are the two terminals of the machine, A being the positive terminal from which the current is supposed to start. Let C be the main or lead from A. Let D be the main or lead going back to the negative terminal, B. The lamps, L L, are joined to these mains by wires as shown, and the current from A divides itself equally (if the lamp resistances are all the same) through these wires and lamps. Here we want two mains. Another similar dynamo would also require two mains, or the two dynamos, working separately, each giving 100 volts, would require *four* mains. We can, however, couple up these two dynamos, so as to get from the coupled machines a pressure of 200 volts. This is done by connect-

* Paper read before the Incorporated Association of Municipal and County Engineers at the Annual General Meeting at West Bromwich, July 13, 14, 15, 1893.

ing the negative terminal of the one machine to the positive of the other, as B to A_1, Fig. 2. The machines apart, we want the mains C, D, E, F; when coupled it is found that one of the mains, D or E, can be dispensed with, saving its cost, and the system then has but three mains, as in Fig. 3. This central main has to carry only a difference of current, hence, usually may have a less sectional area of copper. In practice the area of copper in this third wire is made half that of the mains.

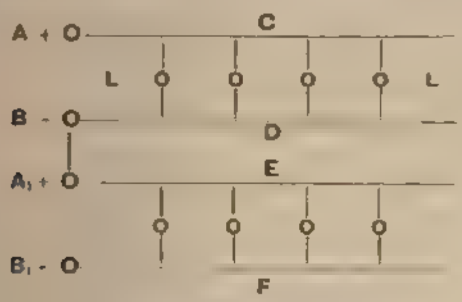

Fig. 2

The total pressure between A and B_1 is 200 volts, but between any two of the mains it is only 100 volts, the pressure required for the due working of the lamps. This, then, is the three-wire system, about which we hear so much, and which, in fact, is a transforming system, without special apparatus, and without much of the loss that pertains to such apparatus. You can easily see for yourselves how the three-wire system can be extended. You will also easily see that there comes to be a point when transformers are to be preferred to mains. A careful examination of the subject will inevitably bring you to the conclusion that the real test all round is cost of maintenance rather than initial cost. It would take too long to discuss this fully, but one phase of it may be examined, and for this particular examination I am indebted to a friend. His contention, with which I fully agree, is that cost price and cost of maintenance of mains affect differently supply companies and municipalities.

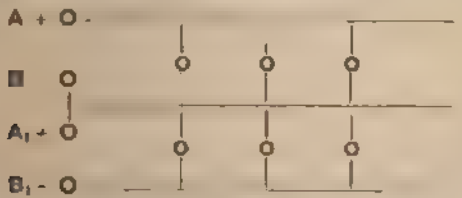

Fig. 3.

Assume the question to be whether to use the very best vulcanised rubber cables (as made by the Silvertown Company or any equally good maker) or a less costly insulated cable. The test of time so far has shown that where the best vulcanised rubber cables have been carefully made and laid the cost of maintenance has been very slight, while the prime cost is high. The whole question resolves itself into the cost of money. A supply company pays, say, 5 per cent. on debentures; a municipality gets all it wants at 3 per cent. Now take the two cases:

1. A prime cost of £12,000, and an annual cost for maintenance of £80

2. A prime cost of £10,000, and an annual cost for maintenance of £200.

For a Supply Company.—First system:

£12,000 at 5 per cent.	£600	
Sinking fund, say, at 2 per cent.	240	
Cost of maintenance	80	
Total	——	£920

Second system:

£10,000 at 5 per cent.	£500	
Sinking fund at 2 per cent.	200	
Cost of maintenance	200	
Total	——	£900

For a Municipality.—First system:

£12,000 at 3 per cent.	£360	
Sinking fund at 2 per cent.	240	
Cost of maintenance	80	
Total	——	£680

Second system:

£10,000 at 3 per cent.	£300	
Sinking fund at 2 per cent.	200	
Cost of maintenance	200	
Total	——	£700

These figures are taken at random merely to put the matter in a concrete form, to show that the greater prime cost is warranted by the results so far as the municipality is concerned. They get better materials and better work, and should obtain better results because they can get their money cheaply. There is also the greater convenience to the public when the maintenance is low, because of less interference with streets and roads. It is therefore important to you to know not only the purity and conductivity of the copper, and the insulation resistance, but to know whether the insulation proposed deteriorates with time, and how rapidly. Unfortunately, too little attention has as yet been paid to this item, but slight enquiry will prove that in many cases large amounts have been expended which, rigidly examined, come under cost of maintenance, but have been placed to capital account.

It is impossible to give the exact details of manufacture of all the specimens of mains before you. They are all from well-known makers, whose reputations stand high in the manufacturing world. Some of these specimens are what we call "armoured"—that is, covered with a protecting wire. This is a mechanical protection which will be again referred to when considering methods of laying the mains. Other mains are lead-cased, this lead covering being almost indestructible, and therefore preserving the insulation. Wires insulated with vulcanised indiarubber, and the lead-cased cables are now almost exclusively used in first-class installations if we except the use of bare wire when the insulation is air.

We may without fear take the practice of the Silvertown Company (its lengthy name is the India Rubber, Gutta Percha, and Telegraph Works Company, Limited, but life is too short to say this) as what should be always looked for by buyers. Following the practice in the manufacture of submarine cables, they subject their manufactures to what may be practically termed continuous tests. All vulcanised wires, cables, etc., are, during manufacture, subjected to temperatures over 200deg. F. They are all tested in water, with at least 500 volts pressure, after being immersed over 24 hours. The test for insulation is taken after one minute's electrification. A certificate of the test is issued with every length of not less than 110 yards of the standard vulcanised classes. Of course the high-pressure mains are subjected to tests with much greater pressure—generally double the working pressure. The specimens before you have been kindly placed at my disposal by the Silvertown Company, Messrs. W. T. Henley's Telegraph Works Company, the Telegraph Manufacturing Company (Helsby), Messrs. W. T. Glover and Co. (Salford), and the Fowler-Waring Company. With regard to lead-covered cables, the system of covering adopted by Messrs. Siemens is almost perfect. The lead tube is produced from a carefully-prepared solid cylinder of cold lead, which is forced under great pressure in a hydraulic press to flow out in one continuous stream round the cable, thus forming a lead tube without seam, and one which therefore has no tendency to open at the seams or allow the penetration of moisture. After leaving the press, every length of cable covered is put under water, and goes through careful testing to ascertain beyond doubt that it is in perfect condition.

After these preliminary remarks about the cables themselves, I will consider the methods of laying (1) with bare wires, (2) insulated wires and a drawing-in system, (3) protected or armoured insulated wires.

First—The Bare-Wire System.—In order that you may have the very latest information as to the practice, Mr. Crompton has favoured me with the details of what he is doing at Hove. Perhaps the better plan is to give the specification of the work, which is as follows:

Electrical Conductors at Hove.

System.—Wherever there is sufficient depth under the footways the conductors will take the form of the Crompton

system of bare copper strip, strained against and supported upon porcelain insulators in concrete culverts, as shown, Figs. 4, 5, and 6. Where there is insufficient room under the footways for these culverts, insulated cables will be laid drawn into Davis-Crompton cast-iron casings, as shown, Fig. 7. If, owing to the position of the cellars and other obstacles, there is insufficient room for the Davis-Crompton casings, wrought-iron pipes will be singly laid, corresponding in number to the cable ways in the casings. Wherever distributing mains are laid service-boxes will be placed at intervals, so that any house along the route may be readily connected to the system. When the mains cross roads or carriageways they will take the form of insulated cables, drawn into Davis Crompton casings, or, in exceptional cases, wrought-iron pipes.

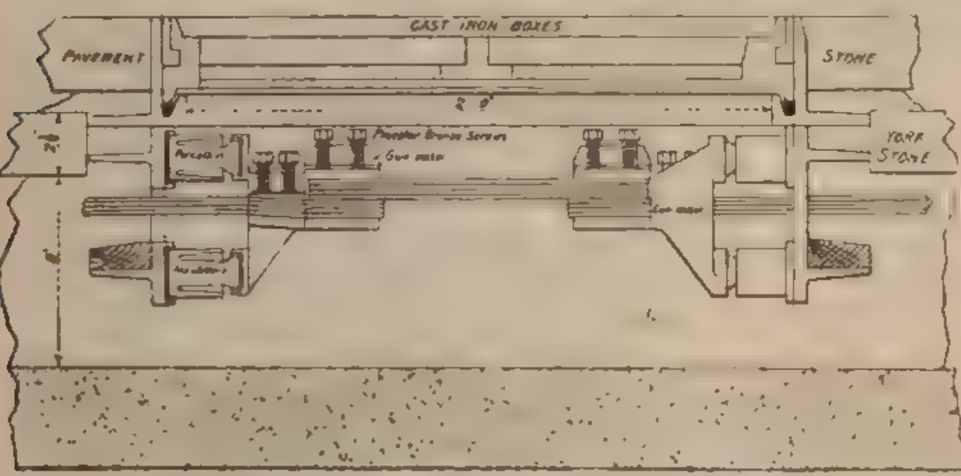

FIG. 4.—Longitudinal Section of Straining-up Box, showing Joints.

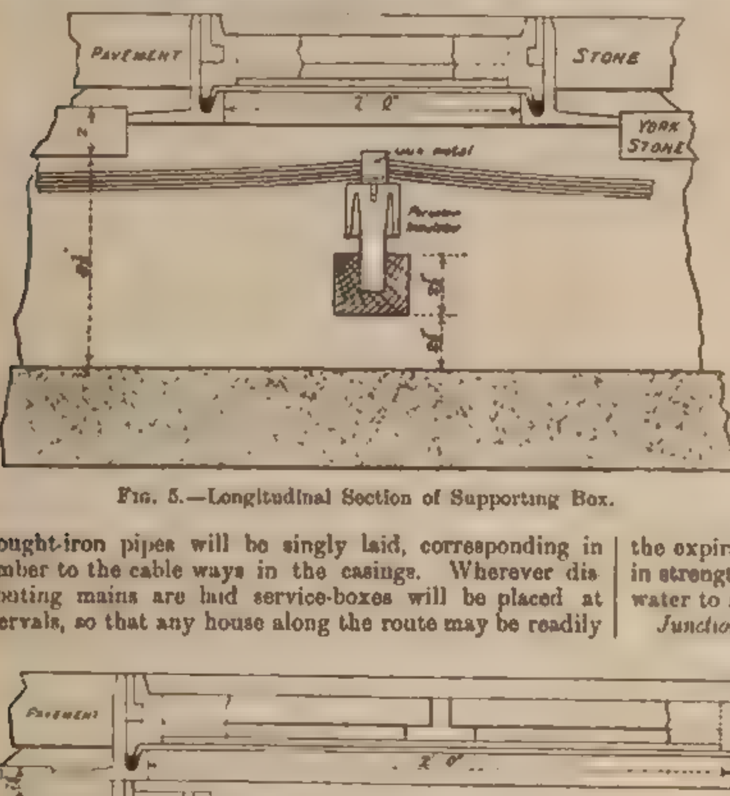

FIG. 5.—Longitudinal Section of Supporting Box.

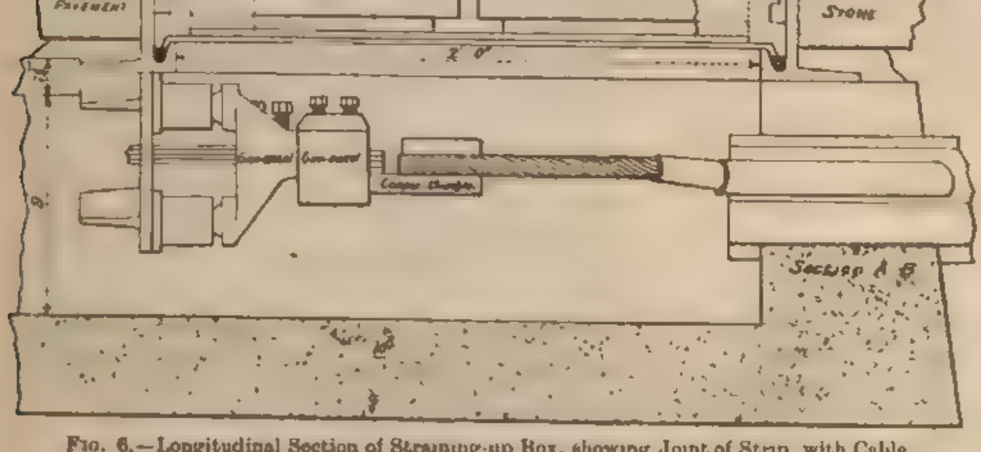

FIG. 6.—Longitudinal Section of Straining-up Box, showing Joint of Strip, with Cable.

Concrete Culverts.—The culverts will be constructed as shown, Figs. 8, 9, and 10, in three sizes—viz., 9in., 15in., and 20in. for three, five, and seven conductors respectively. The sectional area of each of these conductors can be varied from ·125 of a sq. in. to one sq. in. The walls of the culverts will in no case be less than 6in. thick, and the bottoms will be not less than 4in. thick. The culverts will be covered with self-faced York stone, which will be bedded in cement, and all the joints made as watertight as possible. The concrete of which the culverts are to be constructed will be composed of one part of cement to six parts of good pit ballast or shingle. The culverts will be rendered inside with cement and sand in the proportion of four sacks of cement to one yard of sharp pit sand.

Cement.—To be fine Portland cement weighing not less than 112lb. and not more than 116lb. per striked bushel. Briquettes which have been placed in water 16 or 17 hours after gauging, at the end of seven days, to have a tensile strength of not less than 350lb. per square inch, and at the expiration of 28 days from gauging to have increased in strength at least 25 per cent. Pats left in air or placed in water to show no cracks or other signs of deviation of form.

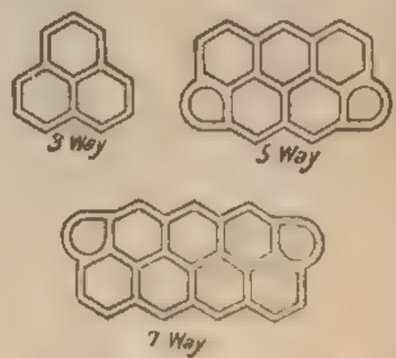

FIG. 7.—Crompton-Davis 3, 5, and 7 way Casing.

Junction and Service Boxes.—The junction and house service boxes will be constructed of bricks wherever Davis-Crompton casings or pipes take the place of concrete culverts.

Drains. — The culverts will be efficiently drained by means of 4in. barrel drains connecting them to the gullies or sewers.

Insulating Gear. — The straining girders will be of cast iron dipped in Angus Smith's composition. The bars on which the supporting insulators rest will be of the best English oak boiled in Stockholm tar. The straining and supporting insulators will be of glazed porcelain carefully annealed. The bridge-pieces will be of gunmetal fitted with manganese bronze or Delta metal screws. The caps for the supporting insulators will be of gunmetal.

Davis Crompton Casings.—These casings will be of good

quality cast iron, in lengths of 6ft. and 3ft. respectively, and will be coated with Angus Smith's composition. These casings to be constructed with three, five, and seven cells, to correspond with the three sizes of culverts. The five-way and seven-way casings will be provided with two extra cells of smaller dimensions for the reception of test wires, telephone or other signalling wires.

Conductors.—The bare copper conductor to consist of strip in every case 1in. wide, the thickness being varied, according to the section required, between $\frac{1}{8}$in. and $\frac{1}{4}$in.—

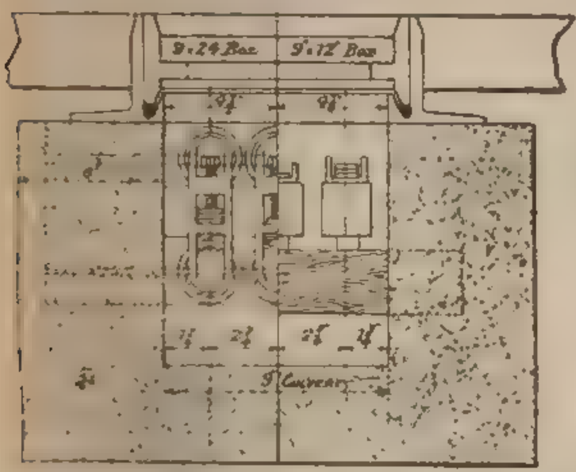

FIG. 8.—Section of 9in. Culvert.

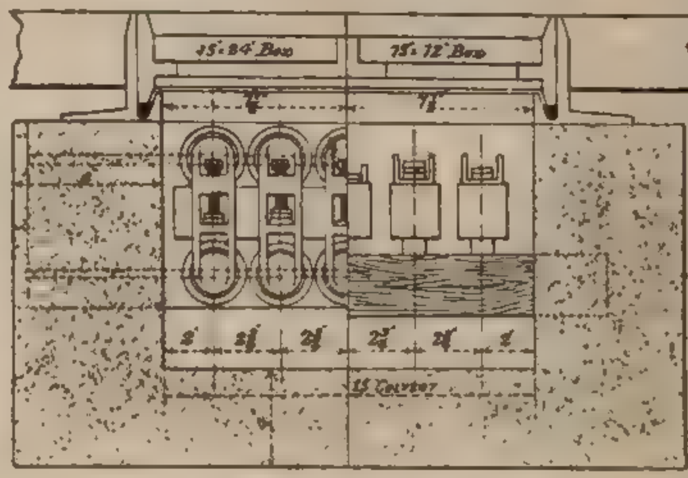

FIG. 9.—Section of 15in. Culvert.

the total cross-section required being built up of a number of such strips superposed. The insulated conductors will have a conductivity of not less than 98 per cent., and the insulating material will be Henley's vulcanised and ozokerited indiarubber, the insulation resistance being approximately 2,000 megohms per mile—the test being applied in the usual manner, in immersion in water before the cables leave the maker's works. The conductors used for test wires being in most cases composed of three $^7/_{22}$ Henley's A A quality conductors made into one triple lead.

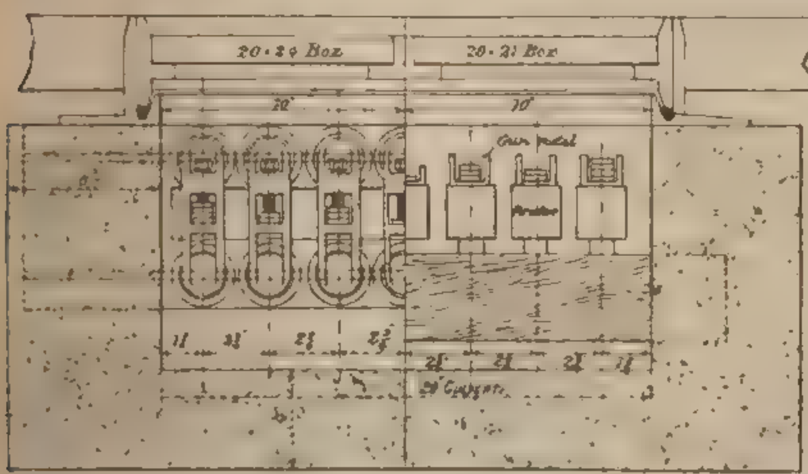

FIG. 10.—Section of 20in. Culvert.

Pavement Boxes.—The pavement boxes will be of the following inside dimensions:

	Junction-box.	House service-box.
For 9in. culvert ...	24in. by 9in. ...	12in. by 9in.
For 15in. culvert ...	24in. by 15in. ...	12in. by 15in.
For 20in. culvert ...	24in. by 20in. ...	12in. by 20in.

They will consist of a cast iron frame, into which a cast-iron cover closely fits, the joints being made watertight by means of a tongue and groove joint with suitable packing. The cast-iron covers may be filled in with cement or asphalte to suit surrounding footways.

It is, of course, impossible to give exact prices, but the following will assist in forming an idea of cost. The prices are for not less than one mile of Crompton underground mains laid at one time, and on the basis of copper at 7d. per pound. The making good of pavements, etc., is not included, as this varies considerably.

3-way culvert; boxes every 15 yards	14s. 5d. per yard.
5 " " "	16s. 10d. "
7 " " "	19s. 10d. "
3-way Davis-Crompton casing "	10s. 3d. "
5 " " "	13s. 3d. "
7 " " "	15s. 0d. "
Insulating gear for the system, per yard run..................................	6d.

Copper strips, jointed and strained up in position	11d. per lb.
5 sectional area cable per yard run laid, A quality	14s. 9d. per yard.
25 ditto	7s. 3d. "
125 ditto....	4s. 0d. "
Triple potential lead per yard run laid	2s. 1d.

Insulated Wires and Drawing-in.—The system just mentioned uses bare copper, and depends upon the air for its insulation. It is not everybody that believes in air insulation even for low pressures, and we all know that it is merely a question of more pressure to break down any air insulation. But while dry air is a good insulator, damp air is not. It is unnecessary to enter into a description of how moisture may condense upon wires and insulators, and thus practically get rid of the insulation of the bare wire. The troubles hitherto arising from the use of the bare-wire system are said to be less in extent than when using insulated wires. I simply deal with the fact that both systems are used, and while it would for numerous reasons be an admirable plan to make a subway or conduit for insulated wires it would add to the cost of laying. There are, broadly speaking, two methods followed—one, the laying of iron pipes in trenches, and subsequently drawing the mains through these pipes, or instead of iron pipes, using bitumen pipes or casings. Whether iron or bitumen be adopted, each main should have a separate tube for its own use. If you have two or more mains in one pipe you cannot draw them in and out without injury to the insulating material, and it is imperative that this should be injured as little as possible. Drawing-in boxes are built at intervals as required. Usually the course of the main is first laid out and the trench dug to the required depth. The trench is made in as straight a line as possible, and is carefully levelled, a good foundation being obtained by ramming, or sometimes by a layer of concrete. As long lengths of trench are operated at a time as the authorities will allow. If bitumen casing, Fig. 11, is used these are in 6ft. lengths, and have to be jointed *in situ* so as to obtain one continuous casing. If I may digress here for a

moment it is to say that one of the most important operations connected with mains is the jointing, and the jointing of the casing is not less important. The great objection is to moisture, and if the casing is not properly jointed moisture will get to the insulated wire. Mice and rats are also pests to be avoided. They are no respecters of insulation, and no

Fig. 11.

doubt many a one has met his death from nibbling where not wanted. To resume, two lengths of bitumen are laid close to each other with, say, 2in. space between. Mandrels are pushed through each hole in the casing joining the two sets of holes together. Hot bitumen concrete is then run round and shaped to the shape of the original casing. The mandrel is furnished with a hook to which a cord is attached, so that when withdrawn the cord is run through the casing; this, of course, being required for the drawing in of the main. Where mandrels cannot be used, the ends are butted together and a saddle, Fig. 12, of the material

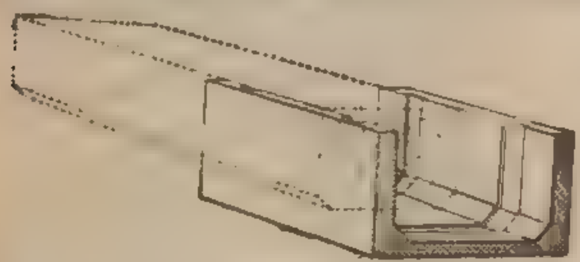

Fig. 12.

placed round, the joint being made sound by a little bitumen seared with a hot iron. When iron tubes are used, similar care is taken to get waterproof joints. The drawing in boxes are of various sizes, generally constructed of brickwork, and well drained. The casings, whether iron or bitumen, project a few inches into the pit, one form of which is shown in Fig. 13. The cover plates are of iron, filled in with cement to match the pavement. The cost of this system varies considerably, principally through the

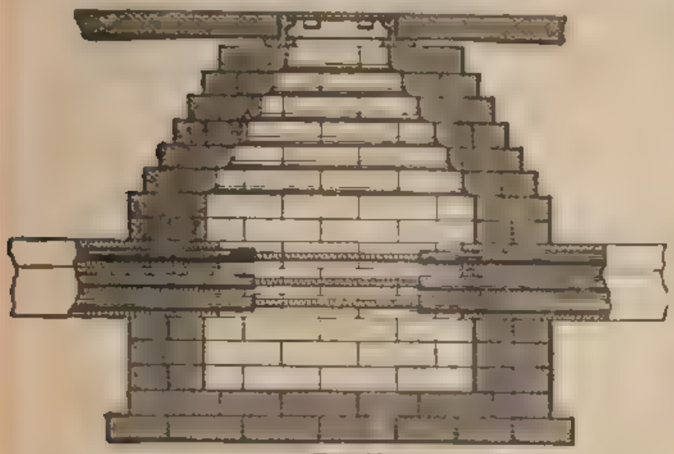

Fig. 13.

different prices charged for excavating and making good. Thus we may take it that—

Cost of excavating and making good varies from 3s. 6d. to 20s. To whatever this comes to must be added:

Cost of casing, iron or bitumen.

Cost of laying casing—say, 2½d. to 3d. per yard for iron.

Cost of cable (10 per cent. off list prices delivered in England).

Drawing in cable, jointing, superintendence—say, 2d. to 4d. per yard.

Drawing-in boxes—say, 1s. per yard.

Of the advantages claimed for the drawing-in system, that which will commend itself to your notice is the ability to examine, repair, or replace the wires without interference with the street traffic, and without much interference with the pavement traffic.

Using Protected Wires.—Some engineers contend that once a main is laid it should not require repair or replacement, if of proper dimensions, properly insulated, and properly laid. They therefore adopt a main covered with iron wire or tape sufficiently strong to resist the blow of a pick or a shovel and lay it in a trench. Others modify this a little, and make a wood trough, into which the wire is placed upon a bed of bitumen or other insulating material. The trough is then filled up with similar material, the top put on, and the trench filled in. Service-boxes are placed at intervals, so that connections can easily be made.

In either of the systems mentioned, it is often arranged that the district lighted is divided into smaller areas, each of which is supplied by its own distributing system, each such distributing system being supplied by special feeding

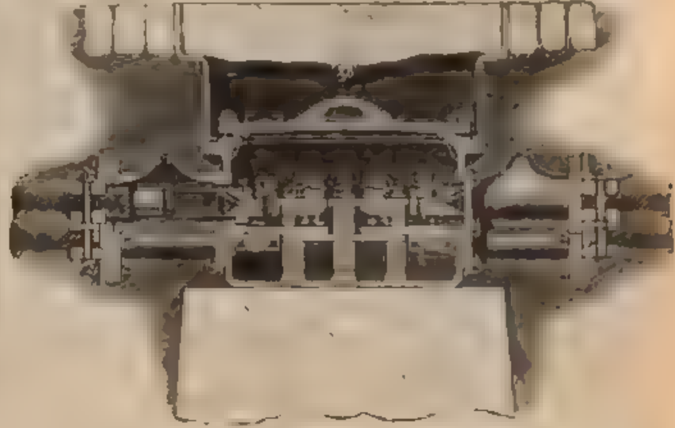

Fig. 14.

wires. In these cases the ends of the feeding mains are led to distributing boxes, from which it may be a number of pairs of distributing wires are led. Messrs Siemens's arrangement for these feeding-boxes is shown in Figs. 14 and 15.

The feeding-boxes consist of a square cast-iron box with a cast-iron cover, over which is a separate manhole frame reaching up to the level of the road or footway, and closed by stone slab with a ring bolt for lifting, or by an iron frame with wood paving as circumstances and locality require. In the cast-iron box there are two sets of contact bars placed vertically above one another, resting on, and

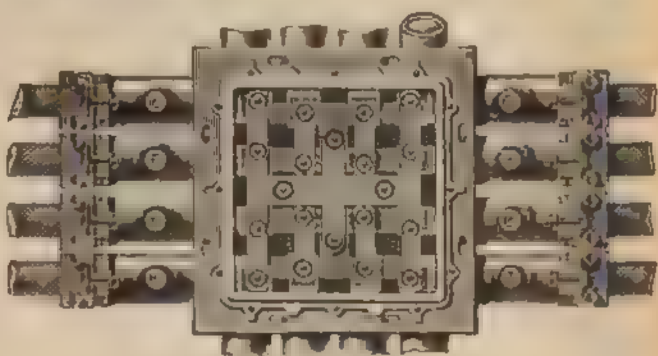

Fig. 15.

insulated by, ebonite pillars, one set being for the positive and the other for the negative mains. Opposite each of the terminals belonging to the two contact bars are circular holes cast in the walls of the box, which serve for the introduction of the cables. Holes in the sides of the boxes which are not immediately required for cables must be closed with blind flanges and india-rubber washers to prevent moisture entering the box. The cables are fitted with end connections, and are brought into the feeding-boxes through coupling boxes, Fig. 16, which being bolted to the feeding-box and to the cable hold the

latter rigidly in position. The coupling-boxes are filled with hot compound, and moisture is thus prevented from entering the cable ends or the feeding-boxes. Feeding-boxes for cables laid on the three-wire system have three sets of contact bars instead of two, but are otherwise of the same construction as those described above, and the connections are made in exactly the same manner.

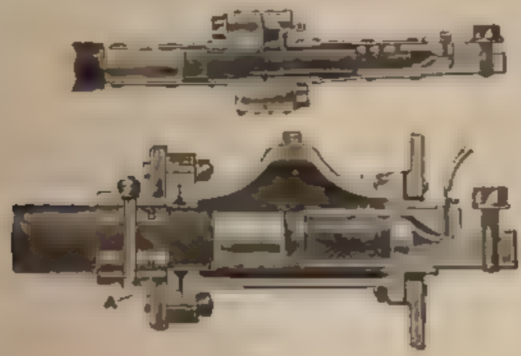

FIG. 16.

Among the mains which are laid according to the last plans are those of Mr. Ferranti, who, as I have said, takes concentric tubes of copper and insulates them from each other. These tubes are in 20ft. lengths, and are insulated the one from the other by means of waxed paper. The paper is thoroughly dried and then saturated with wax, and placed around the inner tube by means of rollers, great pressure being put upon it to make a solid insulation. The insulated concentric tube is then slipped into a second

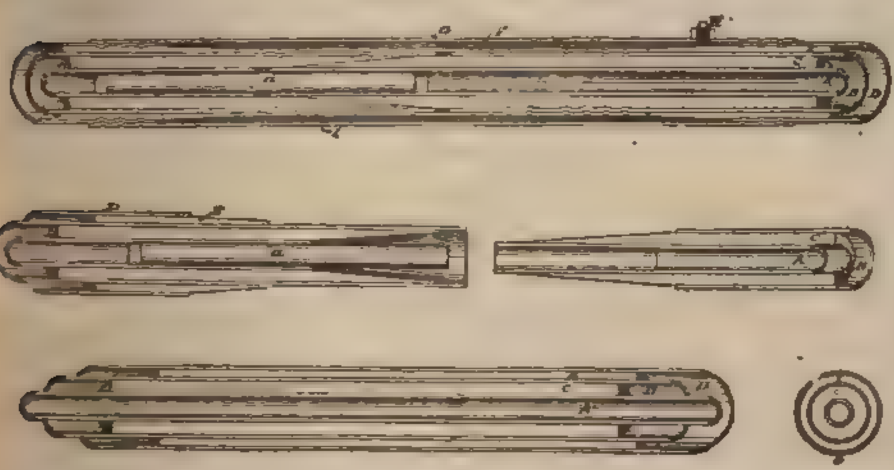

FIG. 17.

tube, which is similarly insulated, and the whole slipped into an outer iron tube to act as a protecting shield. Melted wax is forced in between the tubes, completely filling the space and making the insulation perfect.

But the principal reason for my calling attention to this concentric conductor is from the interesting manner in which the joints are made. The accompanying figures (Fig 17) show sections of the main and method of jointing. One end of each length is formed into a long projecting cone, the other end into a hollow cone by means of a special

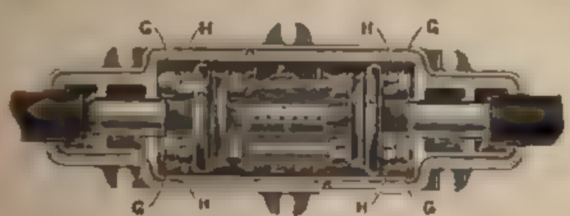

FIG. 18.

lathe. This operation is to exactly the same taper, and the lengths are capped and sent out to the spot in the following manner: A tight-fitting copper rod, 12in. long, is driven into the inner tube of the hollow coned end. A tight-fitting sleeve of copper is driven for a distance of 8in. on the outer conductor of the main to which it is to be jointed, and firmly gripped by a special tool. The two cones are then inserted one within the other, the surfaces having been previously warmed, and are forced together and driven home by screw clamps, a total pressure of about three tons being employed. While under this pressure the copper sleeve is firmly locked to the outer conductor by means of circular corrugations. The sleeve and the outer insulation are wrapped at the junction with insulating material until they become of the same external diameter as the iron tube, when an iron sleeve, 30in. long, is passed over the joint and corrugated down at both ends. In order to fill up any air space in the outer insulation, hot wax is forced through the boss of the iron sleeve. It is then closed with a gas plug. Many thousands of joints have been made in this manner, and when carefully done have been satisfactory.

Some manufacturers have approached the jointing of concentric cables—not the copper tubes, but concentric wire cables similar to those before you — in a different manner. The system adopted by Messrs. Siemens for straight joints, Fig. 18, is a longitudinal cast-iron box, A, in halves, for the protection of the joint. A tinned brass tube, B, to connect the two central conductors, and four tinned metal flanges, C C, D D, with two tinned copper bolts, E E, to connect the two outer conductors. Two of these tinned metal flanges, D D, have ebonite rims round their circumference to prevent the internal fittings from making contact with the outer cast-iron box. The inner conductor is jointed, and the cast-iron box is made watertight. Fig. 19 shows a T-joint for concentric cables, consisting of a T-shaped cast iron box, A, in halves, for the protection of the joint, a tinned brass socket, B, for joining the central conductors, also T-shaped, and six tinned metal flanges, C D, with one tinned copper bolt, E, four tinned steel bolts, F, three tinned steel screws, G, and two strips of tinned sheet copper to connect the outer conductors. Three of these tinned metal flanges, D D, have ebonite rims on their circumference to prevent the internal fittings from making contact with the outer cast-iron box.

There are similar arrangements for jointing lead-covered cables, but the difficulty of deciding what to say within the limits of a short paper must be an excuse for now expressing a hope that at some future time I may perhaps be permitted to deal in an elementary manner

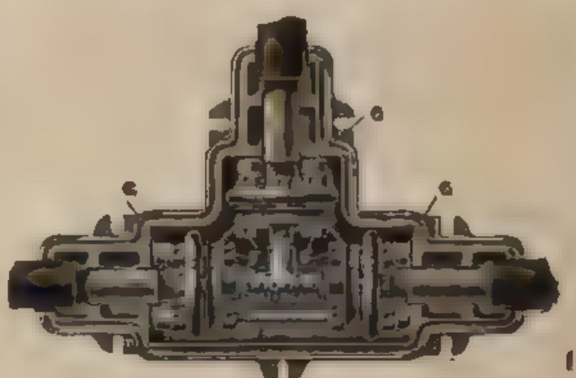

FIG. 19.

with the electrical branch of the subject, and a consideration of the two will enable us better to decide which combination is most likely in practice to be economical and effective.

THE NATIONAL TELEPHONE COMPANY.

This company now justifies its name, for it has succeeded in practically obtaining control of by far the larger part of the telephonic interest of the country, and, according to the report just issued, has made arrangements for acquiring the Telephone Company of Ireland. The accounts to be presented to the meeting next Tuesday are worthy of careful consideration. Unfortunately, with all the will in the world, the exact position of a company is rarely obtainable from its published accounts. The authorised capital of this company is four millions, and it has expended some £23,000 over this huge amount. Some £300,000 of the capital is in 6 per cent. preference shares, and of debenture stock £726,477 has been issued. During the past financial year £344,776 has been expended on purchasing other companies, and £305,799 in constructional work. The largeness of the transactions during the past year are seen from the fact that there is £70,000 advanced by the bankers, and £120,000 by the New Telephone Company, on which interest is paid. The reserve fund seems to have been used to the full, but of course the most important question is the relation of the balance between revenue and expenditure to capital. The revenue account shows over half a million of receipts, against an expenditure £221,218. 11s. 10d. less, that being the amount of profit to be dealt with. Of this sum, after paying parliamentary expenses, interest on loans and debentures, there remains a balance for the shareholders of £181,562, which, after putting £30,000 to reserve, admits of a 5 per cent. dividend on the ordinary and third preference shares, and 6 per cent. on the first and second preference shares, leaving £2,194. 14s. 3d. to be carried forward. The directors in their report say: "The distribution on the ordinary shares of 1 per cent. less than in the preceding year is recommended by the Board chiefly in view of the desirability for strengthening the position of the company by carrying an adequate annual sum to the reserve fund." Some readers may look through the published accounts for evidence of allowance for depreciation, but an item under that heading will not be found. We take it that the directors would say their policy is to maintain their lines in the highest state of efficiency—that such maintenance is charged to revenue and paid for out of revenue, and there is an item of over a hundred thousand pounds for maintenance and renewals. That policy is to be commended, but we do not think that the value of the property is the value of the capital expended on it. The business may be very lucrative, and therefore lend itself to the much watering of capital; but the fact that such a lucrative business is unable to carry its shares to par shows a source of weakness somewhere. This report and balance-sheet comes at an opportune moment. Perhaps before these words see the light another report may be issued—that of the joint committee to determine questions of telephony *v.* traction. Will this report be favourable or unfavourable? If the latter, what effect will it have upon the telephone interests? It is not our province to predetermine this report,

but one thing is evident, that if it be unfavourable, the National Telephone Company will be compelled to alter its whole system to a twin-wire system. This work may not have to be carried out at once, but come it must; and the directors are evidently preparing for the inevitable by increasing their reserve by the large sum of £30,000. They have spent enough money in trying to avoid the twin system that would have gone far towards paying for it, and it is time wiser counsel prevailed. As we say, counsel may not be needed, and the work may be compulsory, but even if the report be favourable to the telephone interests—a matter considerably in doubt—we think it would be far wiser for the directors to hasten on the change rather than to delay it.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ACCUMULATOR TRACTION.

SIR,—With reference to Mr. Sellon's remarks in your issue of the 7th inst. on accumulator traction and on our statement re the maintenance rate of 1½d. per car mile for our cells, whether this latter be bald or otherwise, at any rate it is founded on fact. Of course, this, by itself, does not sum up the advantages of the accumulator system, but it eliminates in a satisfactory manner the only doubtful factor which hitherto existed in estimates of the running expenses, and if taken in conjunction with the other results of working—(1) repairs, none; (2) renewals, none since December, 1892; (3) supervision and attendance, next to none; (4) coal bill, reduced; (5) record of stoppages from all causes, almost a blank, all corroborated by the managing director of the Birmingham Central Tramway Company (Mr. Carruthers Wain) at the meeting of the Tramways Institute of Great Britain and Ireland on June 29—then we maintain that our case is proved beyond doubt. Whatever the outcome of the balance-sheet may be, it can only show whether the management has understood to take advantage of thoroughly efficient cells handed over to them to make their line pay or not. The cost in connection with the working of our cells being accurately and reliably determinable to within a small fraction of a penny, the financial results of any line on which they are used will depend entirely upon the management. Economic boilers, efficient engines and dynamos, motors, and gearing, sound rolling stock and permanent way, cheap way-leaves, and a careful watch over the wages expenditure are essentials to success. Where all these points receive due attention the line will pay, provided the traffic warrants its existence.

We did not say in our letter that the working of the Bristol-road section of the Birmingham Central Tramways is cheaper than any direct-current system. The working is not in our hands: we have no voice in the management, and not the remotest check on the expenditure. We do not believe in and never make random statements: they cannot lead to satisfactory results. An offer has been made by us to the Birmingham Central Tramways Company, Limited, to work the line ourselves, guaranteeing a maximum cost per car mile, and this offer we understand is under the consideration of their Board. Regarding the other sections of the Birmingham Central Tramways Company's system, we did not mention them in our letter, and consequently could not have indulged in any comparisons therewith. How the "balance-sheet" can possibly enlighten Mr. Sellon as to the "regular and reliable working" we confess we do not know: we always expected the "daily returns" to supply this information in the most trustworthy and straightforward manner.

In conclusion, we beg to say that we shall be very pleased to have an opportunity of submitting to Mr. Sellon such evidence as will we are confident leave no doubt whatever upon his mind, if he be open to conviction, that we are fairly and honestly entitled to any and every claim advanced by us for our cells and for accumulator traction in this correspondence and on any other occasion.—Yours, etc.,

L. BROEKMAN, Manager,
The Epstein Electric Accumulator Company, Limited.
London, W., July 11, 1893.

ECHOES FROM THE WORLD'S FAIR.

BY ARTHUR F. GUY.

The following jottings are taken by the writer from a conversation held with a friend, Mr. A. L. C. Fell, who has just returned from the scene of the Yankee's "Biggest Show on Earth," otherwise known as the World's Fair at Chicago.

The buildings at the fair are described as most handsome and imposing, and their appearance would lead the casual observer to imagine that they were built from pure white marble, whereas the effect is really produced by wood and plaster of Paris. Nearly all the various structures are adorned with numerous fine moulded statues, which give a finishing touch to their beauty. The illumination of the grounds by night presents a scene of wonderful brilliancy, and provides a perfect feast for the eyes. Probably the most enjoyable way of obtaining a view of the buildings and grounds, is to pay "half a dollar for the round trip," and take a seat in one of the electric launches which ply on the lagoons, then, sat at ease, an ever-changing scene unfolds itself as the boat glides on. The heat during the day is almost unbearable, and it is only when night sets in that any relief is felt and walking made pleasant. The firework displays are on a grand scale, being undertaken by Messrs. Pain and Co., of London. Almost every nation under the sun is represented in the motley crowds that swarm about, and it is most interesting from some vantage ground to watch the curious sights and incidences that will continually present themselves to a sharp observer of human oddities.

Mr. Fell went out primarily on business for his firm—the Laing, Wharton, and Down Construction Syndicate—and was employed in testing, at the works of the General Electric Company of America, the two 350-kilowatt direct-driven alternators which his firm are about to instal in the new station of the City of London Electric Light Company at Bankside. The writer was given to understand that these machines possess many important improvements in construction, details of which he soon hopes to be in a position to publish, as they will doubtless prove of great interest to central station men. The electrical efficiency of these machines is reputed to be extremely high, and from a low load of one-eighth to the full load, a higher efficiency is claimed than any other machine of similar type.

The work at Niagara is progressing very slowly. Although the main tunnel is cut out, it has yet to be lined, and the basin for receiving the water at the head of the tunnel is not yet built.

During a short stay in New York, some interesting information concerning central-station work was picked up. The central station engineers there seem to have very advanced views respecting economy—as an example, in the new Edison station no less a boiler pressure than 250lb. per square inch is used. A great deal of the steam-piping is made of copper, and where wrought iron is used, the flanges are 3½in. thick. The engineer-in-charge stated that now they never put in steam-piping in duplicate, because they have the most implicit confidence in their own distributing methods, and he quite laughed at the writer's friend when he mildly ventured to state that he thought it advisable to always use a ring system of piping wherever possible. One half of this station is to be worked by triple-expansion engines, and the other half by quadruple-expansion engines; but, perhaps, the most striking feature in the whole station is that concerning the economy of heat: every breath of hot air is taken up through chambers inside the station, passed through the main smoke-stack, and so returned to the fire-box of the boilers. The air thus supplied to the boilers is at a temperature of 300deg. F., thus saving the heat energy that otherwise would have been wasted in raising the air to that temperature.

THE CITY AND SOUTH LONDON RAILWAY CARRIAGES.

Notice has already been taken in these columns (see the *Electrical Engineer* of February 3, 1893) of the special features which differentiate the rolling-stock used on the new underground from that which is customary on ordinary surface lines: and reference was then made to the strong resemblance between the South London carriages and the usual type of tramcar with inside seats running lengthways as opposed to the transverse seats of a railway compartment. In this respect, and in the absence of any class distinction, the South London line therefore is on a level with the democratic street tramway.

Since it is more than likely that a number of other electric lines—whether underground, on the surface, or elevated—will be, as regards many of their details, modelled upon the most successful features of the South London Railway, considerable interest will therefore attach to any account which may illustrate or represent in a new light its chief characteristics, and hence the publication of this brief article, together with some engravings from photographs not as yet made public.

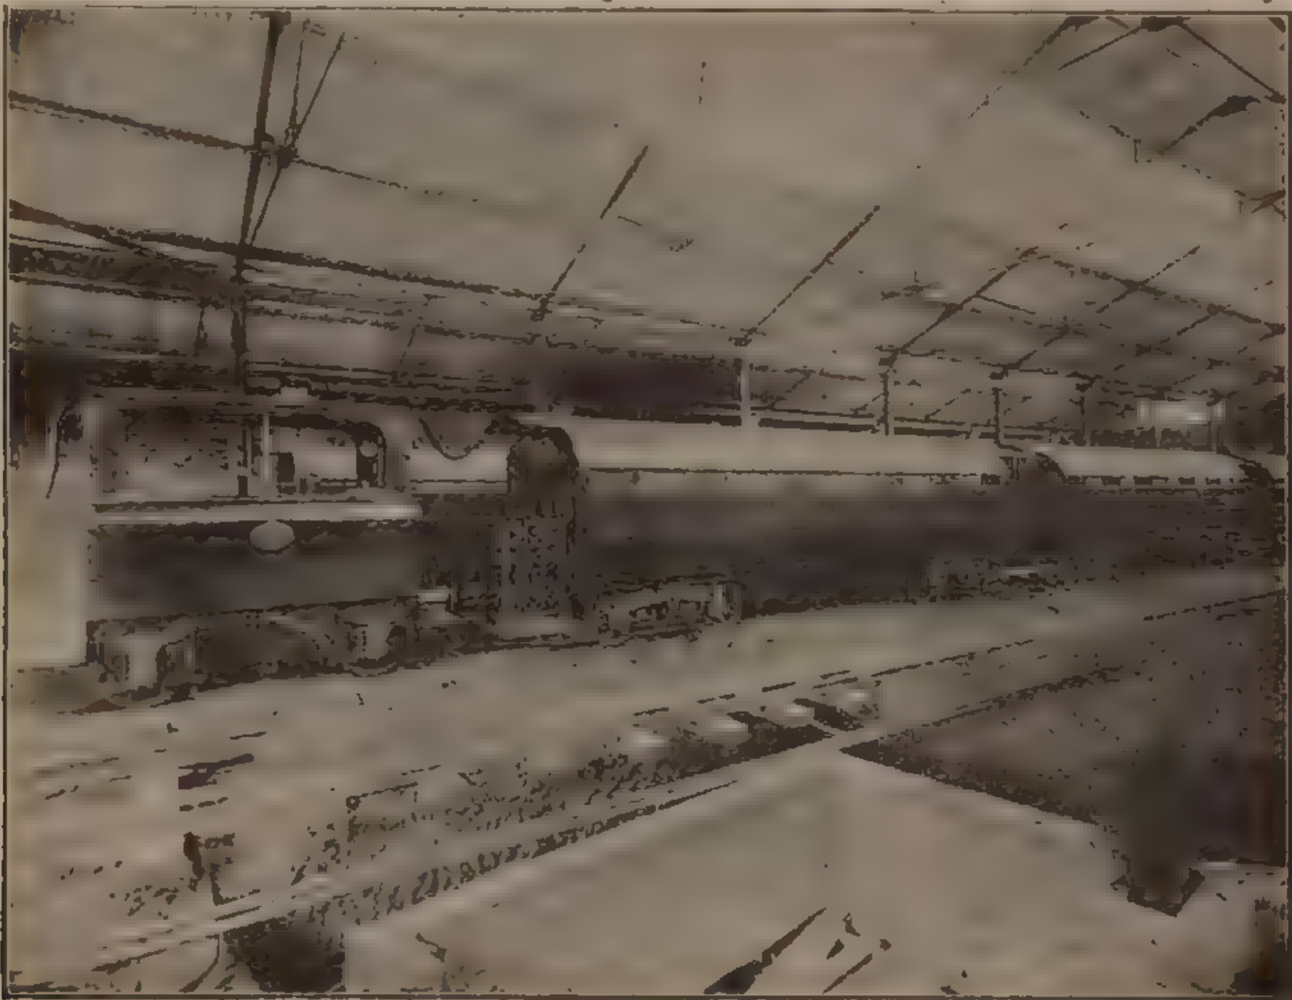
The general aspect of a train upon the South London line will be quite familiar to anyone who has even once travelled on it, but there are many at a distance without opportunities of an inspection, whose interest, however, is keen, and for whose benefit may be set forth the facts. Each train is composed of three carriages and a locomotive: the latter have already been described at length, both when the line was opened and at various times since. Our sole concern is at present with the carriages.

These are each carried on two four-wheeled bogie trucks, and are so connected together that a movable platform carried by the bogie frame swings between each pair of carriages, being independent, therefore, of the carriage frames or bodies. These platforms are covered with a sheet-iron canopy overhead, carried on four pillars of steel rod, and are fitted at the sides with Bostwick collapsible gates.

Down the centre of each carriage runs a passage, and doors are fitted at each end, made to slide in two halves, so that although the carriages make up what is practically a vestibule train, yet each one may be—and is, when running—separated from the others by closing the doors. Passengers are not allowed to stand upon the end platforms while the train is in motion, a guard, or conductor, being put in charge of each platform to open and close the end and side doors as required.

The carriages—as may be seen from the annexed engraving—are each divided in the centre by a transverse partition, with an open archway the full width of the central passage, but without doors of any kind. This arrangement gives the impression of a double carriage, or two compartments. As already stated, the seats are placed longitudinally on each side, and are upholstered both on the seats and backs. Above the back of the seats there are fitted into the side of the carriages ornamental glass panels and mirrors. Four incandescent lamps, supplied with current from the main circuit, serve to light the interior of each carriage, oil lamps being also provided in case of emergency, and for use when the current from the line conductor is momentarily cut off.

Strong representations ought in this respect, however, to be made to the railway company in order to obtain some improvement in the carriage-lighting. The line voltage varies, of course, very considerably, and the incandescent lamps accordingly are found to flicker, greatly to the annoyance of passengers. Some arrangement might very easily—and should—be made for the employment of storage batteries of small size and light weight for illuminating the carriage interiors. These could be carried either on the locomotives or on the bogie platforms, or else underneath the carriage seats; and upon an electric railway one ought at the very least to expect lighting



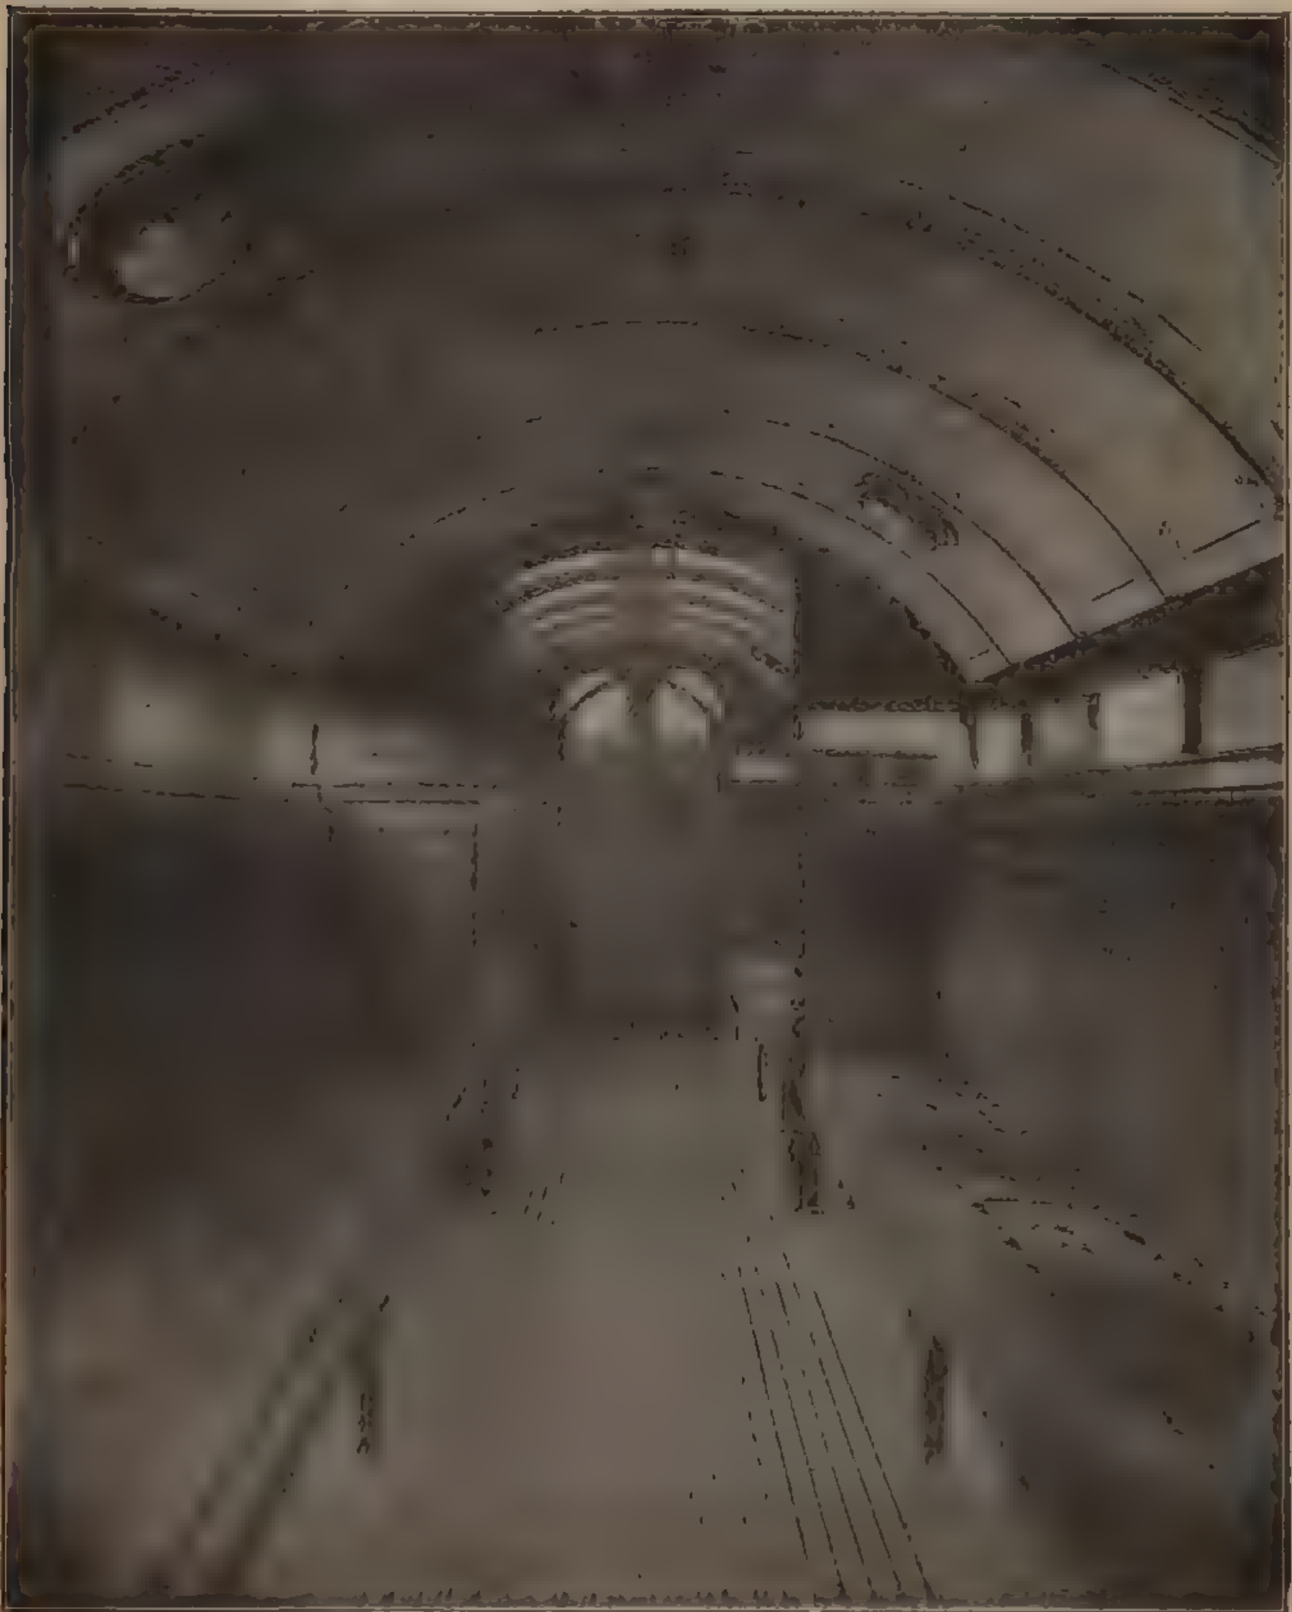
View of Complete Train—City and South London Railway.

capacity as good as may be seen in any of the London omnibuses or tramcars, where small storage cells and incandescent lamps have come increasingly into service.

The carriages are each 26ft. long over the body framing, and the width is 6ft. 10in.—the line being of standard gauge. The height from rail-level to crown of roof is 8ft. 1½in.

scantlings and panels; yellow pine for the roof, floor, and inside casing. Hair felt is inserted under the floorboards and in the sides of the carriage to deaden the noise.

The bogie wheels are 2ft. diameter, and have Bessemer steel tyres and axles; the centres, or hubs, are of wrought iron, Moulmein teak sections being built up to form the wheel body and rim, after the well-known plan adopted by



View of Interior of Carriage City and South London Railway.

The whole of the framework of the bogies is of steel, and so also is the main frame of the body. The side portion of the main underframe is made of a girder in a shape somewhat like the following, in order to allow of the bogies swinging round on a curve.

In the construction of the body the principal kinds of timber employed have been Moulmein teak for both

Mansel. Retaining rings of the Mansel type are also used for securing the tyres to the rims.

The axle-boxes are fitted with oil lubricators, and provided with patent dust shields. Westinghouse automatic air-brakes are used throughout the trains, being operated with air from reservoirs carried upon the trains, and filled when necessary at the termini from large stationary

reservoirs, in which the air is stored at a pressure of 80lb. The quantity carried on each train is usually enough for 30 stops from full speed.

With a full complement of passengers, the average weight of the three carriages which make up a single train may be taken at about 20 tons. The original specifications called for a weight of 4½ tons for each carriage, but this was unavoidably increased to six tons or over. The illustrations that accompany these few details of the South London carriages represent a complete train and the interior of a carriage respectively. For their use, and for the principal facts given in this article, acknowledgment is due to the Ashbury Railway Carriage and Iron Company, Limited, who have built all the 25 carriages constituting the railway company's rolling-stock. F. B. L

COMPENSATORS FOR FALL OF PRESSURE IN FEEDERS FOR DERBY ELECTRIC LIGHTING STATION, MIDLAND RAILWAY.

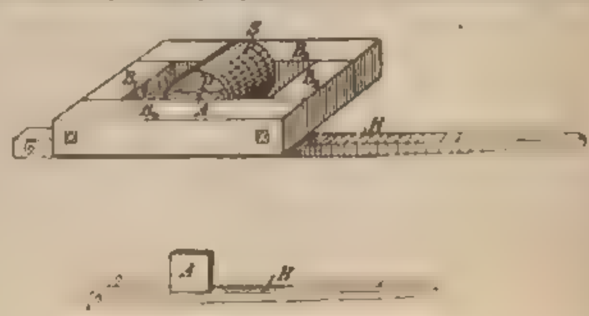
The illustration is taken from a photo of a new compensator for fall of pressure in feeders, constructed on Sayers's new principle by Messrs. Mavor and Coulson, of Glasgow. The compensators have been designed by Mr. W. B. Sayers and his brother, Mr. J. Sayers, of Derby, to keep the pressure constant at the distant ends of the feeders in a low-pressure three-wire system. They will be placed in the engine-room, the current to the feeders which they control passing through them, by which means the pressure is automatically raised by an amount just sufficient to compensate for the drop in the feeders with whatever current may be flowing, thus dispensing with hand regulators and also the necessity for pilot wires.

The compensators proper consist of a pair of low-tension series characteristic dynamos, mounted on the same shaft and driven direct by a motor at a constant speed. The current to the extreme positive feeder traverses one of the armatures of the compensators, and that to the extreme negative feeders traverses the other armature, and the current to each feeder in so doing produces a magnetic flux proportional to itself through the armature and keepers, which form magnetic circuits. The magnetic induction reacts on the winding of the armature, causing an addition of pressure also proportional to the current passing, adjustments being made so that the amount of the added pressure exactly compensates for the drop in the feeders. The manner in which this result is obtained is described in detail in Mr. Sayers's paper recently read before the Institution of Electrical Engineers on the "Prevention of Sparking, etc." In order to compensate for the drop of pressure in the third or centre wire when a current is flowing in it, this current is led around the respective keepers in such a manner as to compensate exactly for the disturbance, which is caused by the drop when a balancing current flows, owing to the two sides being unequally loaded. This is a most important feature, as all engineers who have experience with the problem of keeping pressure constant in a three-wire system will agree. We are unable to describe in detail the way in which this result is obtained, as the patenting process is not yet complete. Two sets of compensators have been constructed for the Derby station—one to carry a maximum current of 500 amperes, and to raise the pressure in the proportion of one volt for every 95 amperes of current flowing, and one to carry a current of 400 amperes and to raise the pressure in the proportion of one volt for every 55 amperes. In each case the third-wire arrangement is adapted for the two outer conductors of the three wire system, each having a sectional area twice that of the central conductors.

SIMPLE APPARATUS FOR COMPARING THE MAGNETIC PROPERTIES OF DIFFERENT KINDS OF IRON.*

BY DR. BEHN-ESCHENBURG, OERLIKON.

This apparatus serves the purpose of comparing different kinds of iron with regard to the strength of the total and residual magnetism with given magnetising forces. The apparatus consists of a right-angled frame of four wrought-iron pieces or blocks, B_1, B_2, B_3, B_4, screwed one to the other; a coil, S, for magnetising; the piece to be tested, P, placed in the coil and screwed to the block B_3; and a wrought-iron plate, A, which fits in exactly between the piece, P, and the block B_4, and may be pushed up by the lever, H, in the direction perpendicular to the block B_4, so that it may be easily adjusted or taken out of contact with P.



Figs. 1 and 2.

There are a few turns of thin wire round the plate, A, and the ends of these may be joined with a ballistic galvanometer. If a current be sent through the coil, S, then B_1, B_2, B_3, B_4, with P and A, form a magnetic double ring. All the lines of force that go through P must also go through A; if, then, with a given strength magnetisation, this plate be

* Abstracted from the *Elektrotechnische Zeitschrift*.

entirely taken out of the magnetic circuit, so that it does not cut any of the lines of force passing through the test piece, it follows that the induction effect upon the wire round the plate will give a measure of the total number, Z, of lines of force which in closed magnetic circuit go through the test piece, P.

Now, if the magnetising current of the coil, S, be interrupted, with closed circuit, there will remain Z lines of force of residuary magnetism, which can similarly be measured by sliding the plate, A, out of the circuit. And if the plate be again placed in position, the magnetising current being interrupted, a measure can be obtained for the lines of force which are still residuary in the iron ring. These lines of force are found to be so few that they may be taken into account only for checking and correction purposes. All the pieces tested by Dr. Behn-Eschenburg were parallelopiped in form, the length being 25cm., and the cross section 81 square centimetres. The plate, A, was 1cm. thick, and its cross-section, as also that of the pieces $B_1 \ldots B_6$, equal to that of the test piece. The coil had 300 turns, in several sections. The current was produced by an accumulator battery. The strength of the current was measured by a Siemens dynamometer. All sources of error from self-induction, etc., were eliminated.

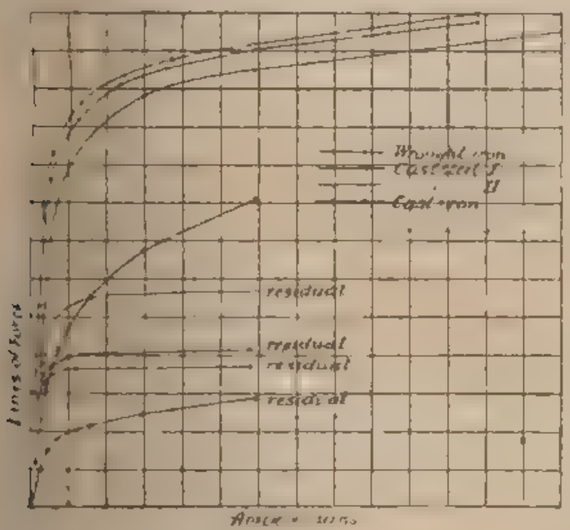


Fig. 3.

The experiments referred to six kinds of iron: (1) wrought iron, (2) Pilsen cast steel, (3) Remscheid I. cast steel, (4) Remscheid II. cast steel, (5) Belgian cast steel, (6) cast iron. The curve for wrought iron was taken as normal. In the curve, diagram 3, only the curves for two kinds of cast steel are shown, the other curves lying between them. The conditions of the experiments were varied as to increase and decrease of the magnetising force, and the results for a given magnetising force agreed remarkably well in repeated tests. The experiments showed that the number of measured lines of force with closed magnetic circuit was greater at the moment of forming the magnetising current than at its cessation, and that the difference increased with increasing ampere-turns, and was greatest where the residual magnetism was greatest. The magnetisation of the iron was continued up to saturation.

Finally, it may be mention that the lever used in the experiments was about three metres long and 5cm. thick, and that a considerable pull, corresponding to about 30kg (66lb.), was required in some of the tests to cause the plate to slide out of the magnetic circuit.

ELECTRIC LIGHTING PROVISIONAL ORDERS AND LICENSES.

REPORT BY THE BOARD OF TRADE RESPECTING THE APPLICATIONS TO AND PROCEEDINGS OF THE BOARD OF TRADE UNDER THE ELECTRIC LIGHTING ACTS DURING THE PAST YEAR.

The following applications for provisional orders have been received by the Board of Trade since the date of the last report.

Title of Order and Description of Area	Name of Promoters.
Altrincham and Bowdon Electric Lighting Order. The Local Board Districts of Altrincham and Bowdon and a portion of the District of the Rural Sanitary Authority for the Altrincham Union	Manchester Edison-Swan Company, Limited.
Barnet Local Board Electric Lighting Order. The District of the Local Board.	The Local Board.
Beckenham Electric Lighting Order. A portion of the Parish of Beckenham	Do.
Bridgend Electric Lighting Order. The Urban Sanitary District of Bridgend.	Do.
Brighton Electric Supply Order. The Municipal Borough of Brighton.	Brighton and Hove Electric Light Company, Limited.
Colchester Electric Lighting Order. The Borough of Colchester.	Corporation.
Eccles Electric Lighting Order. Municipal Borough of Eccles.	Do.
The County of London:	
Hackney Electric Lighting Order. The District of the Board of Works for the Hackney District.	The Board of Works.
Hammersmith Electric Lighting Order. The Parish of Hammersmith.	The Vestry.
Islington Electric Lighting Order. The Parish of St. Mary, Islington.	Do.
Islington Electric Lighting Order. The Parish of St. Mary, Islington.	County of London Electric Lighting Company, Limited.
Poplar District Electric Lighting Order. The District of the Board of Works for the Poplar District.	The Board of Works.
St. Mary, Islington (North) Electricity Supply Order. A portion of the Parish of St. Mary, Islington.	Holloway Electricity Supply Company, Limited.
Newcastle upon Tyne Electric Lighting Order. The City and County of Newcastle upon Tyne.	Newcastle upon Tyne Electric Supply Company, Limited.
Newmarket Electric Lighting Order. The Urban Sanitary District of Newmarket.	British Electric Light Company, Limited.
Partick Electric Lighting Order. The Burgh of Partick	The Commissioners of Police.
Reading Electric Supply Order. The Borough of Reading.	Reading Electric Supply Company, Limited.
Taunton (Corporation) Electric Lighting Order. The Municipal Borough of Taunton and a portion of the District of the Taunton Union Rural Sanitary Authority.	Corporation.

Of these applications (18 in number) 11 were made by local authorities, and seven by companies, while six related to the county of London.

In one instance an application was received from the local authority, and another application from a company, for the same area and a second company applied for an order in respect of a portion of that area. An order was granted to the local authority, and the applications of the companies were refused.

The following statement shows the manner in which the various applications have been dealt with:

Title of Order.	How dealt with.
Altrincham and Bowdon Electric Lighting Order.	Order granted.
Brighton Electric Supply Order	The promoters failed to produce the consent of the local authority, and the Board of Trade directed that a local enquiry should be held. After consideration of the report made by the inspectors appointed to hold the enquiry, the Board of Trade were of opinion that no reasons had been advanced sufficient to justify them in dispensing with the consent of the local authority, and refused to grant the order. The local authority are themselves supplying electrical energy under a provisional order obtained in 1883.
Barnet Local Board Electric Lighting Order.	Order granted.

Title of Order.	How dealt with.
Beckenham Electric Lighting Order.	Order granted.
Bridgend Electric Lighting Order.	Do.
Colchester Electric Lighting Order.	Do.
Eccles Electric Lighting Order.	Do.
The County of London:	
Hackney Electric Lighting Order.	Do.
Hammersmith Electric Lighting Order	Do.
Islington Electric Lighting Order (Vestry).	Do.
Islington Electric Lighting Order (County of London Electric Lighting Company, Limited)	An order was granted to the Vestry, and this application was refused
Poplar District Electric Lighting Order.	Order granted.
St. Mary, Islington (North) Electricity Supply Order.	An order was granted to the Vestry, and this application was refused.
Newcastle upon-Tyne Electric Lighting Order.	Order granted.
Newmarket Electric Lighting Order	The promoters failed to produce the formal consent of the local authority, and the Board of Trade, for the reasons stated in the special report made by them and presented to Parliament, decided to dispense with the consent of the local authority, and granted the order.
Partick Electric Lighting Order	Order granted.
Reading Electric Supply Order	Do.
Taunton Corporation Electric Lighting Order.	Do.

Bills Nos. 1, 2, 3, 4, and 7, to confirm the orders relating to Altrincham and Bowdon, Barnet, Beckenham, Bridgend, Colchester, Eccles, Hackney, Hammersmith Poplar, Newcastle upon Tyne, Newmarket, Partick, and Taunton, were introduced into the House of Commons on the following dates viz.: Nos 1 and 2 on the 29th March, Nos. 3 and 4 on the 25th April, and No 7 on the 30th May.

Bills Nos 5 and 6, to confirm the orders relating to Reading and Islington, were introduced into the House of Lords on the 8th May.

Bills Nos 2 and 3 received Royal assent on the 9th June. Bills Nos 1 and 4 to 7 are still before Parliament.

The Bills to confirm provisional orders granted by the Board of Trade last year, which were before Parliament at the date of last report, all received Royal assent.

In the following instances the Board of Trade have approved deeds transferring to limited companies the powers, duties, and liabilities (with certain exceptions) under provisional orders granted to local authorities

Title of Order.	Originally granted to.	Transferred to.
The Cambridge Electric Lighting Order, 1890.	The Corporation of Cambridge.	The Cambridge Electric Supply Company, Limited.
The Hove Electric Lighting Order, 1890.	The Hove Commissioners.	The Hove Electric Lighting Company, Limited.

LICENSES.

The following applications for licenses have been received since the date of the last report, and have been dealt with in the manner shown below:

Local Authority or Company applying, and District.	How dealt with.
Crystal Palace Electric Supply Company Limited. (Portions of the following districts:- viz. Parishes of Lambeth and Camberwell Districts of the Lewisham District Board of Works and of the Beckenham Local Board, and Borough of Croydon	Still under consideration.
Pontypool Electric Light and Power Company, Limited. (District of the Pontypool Local Government Board.)	License granted Jan. 21, 1893.
The Corporation of Taunton. (The Municipal Borough of Taunton.)	License granted Feb. 3, 1893

Of the applications for licenses referred to in the last report, that of the Ogmore Valley Electric Light and Power Supply Company, Limited, was granted on September 16, 1892. The others are still under consideration.

Appended is a list of the provisional orders confirmed by Parliament (prior to the present session), and of the licenses granted by the Board of Trade since the passing of the Electric Lighting Act, 1882, showing those which have since been revoked or repealed.

Board of Trade, June 27, 1893. COURTENAY BOYLE.

COMPANIES' REPORTS.

NATIONAL TELEPHONE COMPANY, LIMITED.

President: James Staats Forbes. Vice president: Right Hon. Lord Balfour of Burleigh. Directors: Chas. Swain Agnew, George Franklin, Eli Heyworth, Colonel Robert Raynsford Jackson, William Cuthbert Quilter, M.P., George Hunter Robertson, Sir Albert Kaye Rollit, M.P., Samuel Herrick Sands, William Alexander Smith, Alderman Joseph Thompson. General manager: Wm. E. L. Gaine. Secretary: Albert Anns.

Report of the Directors for the year ending April 30, 1893, to be presented to the shareholders at the thirteenth ordinary general meeting of the Company, to be held at the City Terminus Hotel, Cannon street, E.C., on Tuesday, July 18, 1893, at 1 p.m.

The income accrued in respect of the business of the year amounts to £583,590. 2s 11d., as compared with £463,741. 5s. 4d. for the preceding year, being an increase of £119,848. 17s. 7d. The rentals carried forward this year for unexpired terms of running contracts amount to £285,020. 7s 8d as compared with £234,370. 11s 2d for the preceding year, or an increase of £50 649. 16s. 6d. The working expenses and other charges (excluding debenture and other interest) amount to £311,644 10s. 2d., as compared with £236,252. 0s. 5d for the preceding year, being an increase of £75,392 9s 9d. The net result for the year, after deducting the Post Office royalties amounting to £54,220 9s. 10d. is a profit balance of £217 725 2s. 11d., as compared with a balance of £187 249 19s 3d for the preceding year, being an increase of £30,475. 3s 8d. Out of the available balance an interim dividend at the rate of 6 per cent. per annum on the first and second preference shares, and 5 per cent. per annum on the third preference and ordinary shares has already been paid. The Board will recommend a further payment at the rate of 6 per cent. per annum on the first and second preference shares, and 5 per cent. per annum on the third preference and ordinary shares, making the dividend for the year 6 per cent. on the first and second preference shares, 5 per cent. on the third preference shares and 5 per cent. on the ordinary shares. The distribution on the ordinary shares of 1 per cent. less than in the preceding year is recommended by the Board chiefly in view of the desirability of strengthening the position of the Company by carrying an adequate annual sum to the reserve fund. The Board propose, under No. 113 of the articles of association, to transfer to the reserve fund £30,000 (bringing that fund up to £134,027 3s. 6d.), and to carry forward the balance of £2,194 14s 3d. A reference to the capital account shows that during the year the purchase has been completed of the undertakings of the Western Counties and South Wales Company, the Sheffield Company, and several other minor companies. Though involving the outlay of £345,776, the Board believe that these purchases will be advantageous alike to the public and the shareholders as enabling the telephone business of the country to be developed and conducted more efficiently and economically than it could possibly be if carried on in a disjointed fashion by a number of small and separate administrations. Since the end of the past financial year arrangements have been made for acquiring the Telephone Company of Ireland. The Board have had to consider their position in relation to the New Telephone Company, which was launched in avowed competition with the National Company. The promoters of that enterprise soon began to appreciate the serious difficulties which lay before them, and as the result of discussion, accepted the conclusion that if the shareholders were to be secured a reasonable return upon their capital it would be better in the public interest to work in harmony with the National Company, adopting as far as practicable the better features of the two systems. This resulted in an agreement under which the National Company subscribed one-third of the capital of the New Company, and were represented on the Board of that company. Subsequently it became apparent that the policy of the Government in assuming possession of the trunk wires, forming the inter-town communication of the country, would greatly complicate the position of the licensed companies, and make unity of administration and interest essential to efficiency and success; therefore, upon the sudden death of the late Duke of Marlborough, who was the enthusiastic and moving spirit of the New Company, those who were associated with him recognised the necessity of still closer union with the National Company, and matters have ended in the National Company acquiring, partly by purchase and partly by the exchange of New Company's shares for National shares, nearly the entire interest in the New Company. During the year negotiations of a difficult and complicated character in relation to the acquisition by the Government of the Company's trunk lines have been carried on with the authorities of the Post Office. The Board are gratified to be able to report that a draft agreement is now in course of preparation, which it is hoped may be shortly accepted and ratified by the contracting parties. The rapid growth of the Company's business, and the expansion of its territory consequent upon the absorption of the several minor companies, coupled with the increasing responsibilities of the Board involved in the closer relations with the Post Office, pointed to the importance of bringing into the counsels of the Company some new members of a certain public position and experience. This necessity was unanimously recognised, and acting in the spirit that no question of personal interest should stand in the way of the interest of the shareholders two vacancies were created by the voluntary retirement of Mr. John Bruce and Mr. Peter Garnett. The Board, under the powers conferred on them by the articles, were enabled to fill up these vacancies by the election of Lord Balfour of Burleigh and of Sir Albert K. Rollit, M.P. The same spirit

which actuated his two colleagues was displayed by Colonel R. Raynsford Jackson, who readily vacated his position as vice-president of the Company in order that it might be filled by Lord Balfour of Burleigh, whom it was considered desirable to place in that important office. At the general meeting four Directors retire, and being eligible offer themselves for re-election, viz., Lord Balfour of Burleigh, Mr. Charles Swain Agnew, Mr. George Hunter Robertson, and Sir Albert Kaye Rollit, M.P. Lord Balfour of Burleigh and Sir Albert Kaye Rollit, M.P., elected to retire, considering it would be respectful to the shareholders to submit their recent selection by the Board to the judgment of the proprietors. The auditors, Messrs. Welton, Jones, and Co., also retire, and are eligible for re-election.

AUTHORISED CAPITAL.

15,000 6 per cent. first preference shares of £10 each	£150,000
15,000 6 per cent. second preference shares of £10 each	150,000
250,000 5 per cent. third preference shares of £5 each	1,250,000

Lamina Accumulator Elieson's British Patents' Syndicate, Limited.—This Company has been registered by Bullock, Bourner, and Thomson, 10, Throgmorton avenue, E.C., with a capital of £12,000 in £1 shares. Object: to carry into effect an agreement for the acquisition of certain patents relating to improvements in electric accumulators or storage batteries, and to develop and turn to account the same, and to carry on business as electricians and electric engineers generally. Table A mainly applies.

BUSINESS NOTES.

West Hartlepool.—This Town Council have appointed a committee to consider the price of gas in the town, which is held to be excessive.

Bombay.—The Bombay Municipality have renewed their gas contract for a year only from July. They wish to test the Welsbach and other burners.

Bolton.—The Bolton Corporation invite tenders for alternators and dynamos for their central station. Particulars will be found in our advertisement columns.

Liverpool Overhead Railway.—For the convenience of visitors to the sands at Seaforth a special late service of trains is being run on the Liverpool Electric Railway.

Western and Brazilian Telegraph Company.—The receipts for the past week, after deducting 17 per cent. payable to the London Platino Brazilian Company, were £2,372.

Worcester City Council.—The note last week headed "Birmingham" was by error attributed to this Town Council, whereas it should have referred to the Worcester City Council.

Croydon.—The Croydon County Council have resolved, subject to the sanction of the Local Government Board, to adopt the electric light in the centre of the borough, at an estimated cost of £25,000.

Caledonian Electric Supply Company, Limited.—This Company has been established with a nominal capital of £100, divided into 100 shares of £1 each. The registered office of the Company is in Edinburgh.

St. James's and Pall Mall Electric Light Company, Limited.—The Directors have declared an interim dividend for the half year ending June 30, 1893, at the rate of 7 per cent. per annum on the preference shares.

Portsmouth.—The tender of the International Electric Subway Company for electric mains for Portsmouth has been accepted, and the Johnstone system, which is the specialty of this company, will be laid throughout.

Appointment.—The Huddersfield Electric Lighting Committee require the services of an assistant electrical engineer accustomed to high-tension alternate-current working. Application by the 24th inst. to the Town Clerk, Huddersfield.

Personal.—Mr. Claude W. Hill, A.M.I.C.E., has been manager of Messrs. Paterson and Cooper's works, Pownall road, Dalston, since July last. Letters to him should be addressed there, and not to his late address—5, Parsonage, Manchester.

City and South London Railway Company.—The receipts for the week ending July 9 were £1,069, against £733 for the same period last year, or an increase of £336. The total receipts for the second half-year of 1893 show an increase of £336 over those for the corresponding period of 1892.

Tunbridge Wells.—At the monthly meeting of the Town Council last week, Alderman Clifford, on behalf of the Electric Light Committee, again brought forward the proposal to adopt electric light for Tunbridge Wells at an outlay of £13,000. On a show of hands the committee's report was adopted by 16 votes to 9.

British Museum.—The new arrangements for the lighting of the British Museum reading room will allow of the setting up of nearly 200 lights, and it is expected that everything will be fitted for the use of the new illuminant not later than the middle of August, or some weeks before the commencement of the next season.

Tiverton.—At the Tiverton Town Council last week, it was reported that Sir Thomas Bloomfield, the head of the Electrical Department of the Board of Trade, would advise the Board to extend for one year the powers of the provisional order for the supply of electric light in the town, which was considered satisfactory.

Eastbourne Parade.—At the Eastbourne Town Council meeting last week Alderman Homewood moved, Councillor Martin seconded, and it was resolved: "That the common seal be affixed to an agreement between the Eastbourne Electric Light Company, Limited, and the Corporation of Eastbourne for lighting the Royal parade by electricity."

Proposed Electric Tramway at Edinburgh.—At the last meeting of the Edinburgh Town Council a letter was submitted on behalf of the Caledonian Electric Supply Company, Limited, with notice, in terms of Section 4, Sub-Section 1 of the Electric Lighting Act, 1882, in connection with proposed electric tramway from Coltbridge to Corstorphine.

Blackpool Lighting.—Councillor Pearson, at the Blackpool Corporation meeting, said he thought the electric supply would be ready about the first week in August, or possibly the second, the whole of the town, as regarded private lighting. He had had interviews with the contractors and Mr. Wolstenholme, and he thought the public would not be disappointed.

Glasgow Municipal Buildings.—The minutes of the Committee on Municipal Buildings of the Glasgow Corporation stated that the sub-committee had authorised the extension of the electric lighting over the whole building with the exception of the basement, the committee room corridor, and Burgh Court Hall. The estimated cost is £2,000. The minute was approved.

Perth.—At the monthly meeting of the Perth Town Council, a letter was read from the Caledonian Electric Supply Company, Limited, stating that application was to be made to the Board of Trade for a provisional order authorising the company to supply electricity within the burgh of Perth, and asking the consent of

the Corporation. The communication was remitted to the Lord Provost's Committee.

Athletic Association.—Mr. Dane Sinclair recently presided at an enthusiastic gathering of the London staff of the National Telephone Company, at which it was decided to form a sports club, to be called "The Telephone Athletic Association." A provisional executive committee was appointed to arrange details, with Mr. T. C. Walker as treasurer and Mr. W. E. Deane as secretary, and a large number of members have already been enrolled.

Whitehaven.—At the monthly meeting of the Whitehaven Town and Harbour Trust the chairman said they would observe the laying of electric mains was progressing but the progress, unfortunately, was not quite so rapid as it ought to be, as the time expired on July 1, and there still remained a good deal of work to be done. Still the work was going on fairly regularly and rapidly, and he expected it would be finished in the course of three weeks.

Sheffield.—The Sheffield Works Sub-Committee in their report, which was adopted by the Highway and Sewerage Committee, have considered the question of the transformer chambers proposed to be constructed by the electric lighting company, and have decided to allow the company to place boxes near the Monolith, in White Bear walk, the Market place, top of East parade, Water lane, Norfolk street, and the junction of Westbar and Spring street.

Morecambe.—At the monthly meeting of the Morecambe Local Board on Tuesday, a memorial was read from property owners in the vicinity of the electric light company's central station complaining strongly of the nuisance caused by the noise of the engines and the smell of exploded gas. The reports of the medical officer and the surveyor on the matter were also read, and it was resolved to forward the whole correspondence on the subject to the Local Government Board, asking if the Board can take the matter up.

Birmingham.—The General Purposes Committee of the Birmingham City Council had under consideration the question whether the Corporation should themselves obtain a provisional order for the supply of the electric light, and consequently oppose the extended order asked for by the Birmingham Electric Supply Company. The consideration was adjourned. The *Daily Post* now states that after long and careful enquiry the committee at their meeting on Monday decided that it would be inadvisable for the Corporation to undertake the supply of electricity, and will report to the Council at its next meeting in that sense.

Arbitration Clause in Contracts.—In a circular sent out by the London Chamber of Commerce on the 17th January last, the text of a clause for use on contracts was incorporated which provided for the reference of all disputes thereunder to the London Chamber of Arbitration. Some objection having been taken to the length of that clause, the matter has been reconsidered, with the result that the council now recommend the use by members of the following stipulation: "All disputes which may arise relating to this contract shall be submitted to arbitration under the rules for the time being of the London Chamber of Arbitration."

Dundee.—At the last meeting of the Dundee Gas Commission a report was submitted from Messrs. Urquhart and Small, consulting electrical engineers, London, stating that the various contracts in connection with the introduction of the electric light into Dundee had been carried out to their satisfaction. Certain alterations had been effected in the matter of details; and it was suggested that the Commission should consider an offer to have the batteries maintained for an annual payment of £80. The Commission expressed approval of the manner in which the installation had been gone about, and it was reported that the installation had cost £19,007. 12s. 7d. This includes £599. 8s. 4d. of extras, or 1·6 per cent. of the total contracts.

Bradford.—At the Bradford Town Council meeting, Mr. James Kay, deputy chairman of the Gas and Electricity Supply Committee, moved, and Mr. George Newby seconded, the adoption of the minutes, which contained particulars of correspondence and interviews with Lord Kelvin as to the mode of extending the electricity supply works, and his Lordship's report was given. It was stated that Lord Kelvin had been invited to meet the committee in Bradford at an early date for the purpose of conferring with them before the course to be taken was determined upon. The minutes included a resolution advancing the salary of Mr. Mitchell, assistant electrical engineer, from £125 to £150 per annum. These parts of the minutes were adopted.

Stafford.—At the Stafford Town Council monthly meeting the committee reported that they had had before them various names of electrical engineers, and recommended that the services of Dr. John Hopkinson, of London, be retained. Alderman W. H. Peach, in moving the adoption of the report, stated that from a list of 12 gentlemen well known in the electrical world the committee selected Dr. John Hopkinson, whose name was very well known in connection with electrical matters. He was the inventor of the three-wire system, and was a man of perhaps greater experience than anyone else whom they could possibly get. At the present time he was engaged in carrying out a large installation for the Manchester Corporation, and also a smaller one for the town of Whitehaven, and the committee felt confident in his giving a satisfactory report. His fee would be 100 guineas, including expenses, and they expected a visit from him during the present week. The report was adopted.

Accrington.—At the meeting of the Accrington Town Council last week, Mr. Riley asked if anything had been heard from the Local Government Board with reference to the borrowing powers for the electric light scheme. It seemed to him that the thing had gone dead altogether. The Town Clerk replied that the matter had not gone dead; but the time of the Legal and Parliamentary Committee had of late been so much occupied with the gas and water question that they had not been able to do anything with regard to the electric light. The Local Government Board had given their sanction to the borrowing of money for the scheme, but it was not a very satisfactory sanction, as the Board had grouped the land, machinery, etc., together, and only offered the Council 25 years for repayment. That was outrageous. They ought to have the same length of time for repayment for the land for the electric light as they had for the baths—50 years—and until they had that he would not recommend the Council to accept the sanction.

Margate Hotels.—The hotel accommodation of Margate has received an important addition in the erection of the Hotel Metropole, a very fine structure facing the jetty and close to the sea, opened on June 24th. It has been erected on the site of the Grand (which was destroyed by fire two years since) and adjacent buildings, and is under the management of a limited liability company, of which Councillor W. Leach Lewis is chairman and Mr. Walter Hills solicitor. It was designed by Mr. Albert Latham, the borough engineer, and built by Mr. Jesse Goldsworthy, and consists of about 120 rooms, which have been elaborately furnished by Messrs. Edwards and Roberts, of Wardour street. Property has also been acquired for the erection of 50 more rooms. Throughout the building the electric light is used. The sitting and other rooms overlook the sea, and the hotel will prove an additional attraction to the town. The sanitary arrangements are perfect, and baths have been provided on each floor.

Politics and the Electric Light.—At the Northampton Town Council Mr. Mills moved the Town Hall Committee's report, which contained a recommendation that the old reading room be cleaned and done up in a plain substantial manner. Mr. Mills said that the cost of doing up the room would be about £18. There was the additional question of fitting the room up with the electric light, and the estimate for that was £30. The committee had just had a meeting and considered the electric light question, but they were not prepared to report. He believed the committee would be glad of an expression of opinion on the part of the Council on that point. A discussion ensued as to which political party were to have the use of the room. Dr. Buzzard then moved that permission be not given for the electric light until a statement had been made and laid before the Council as to the uses to be made of the room when it was renovated and done up, and also the price to be charged for the use of the room. After a little discussion, Dr. Buzzard withdrew the amendment at the suggestion of the Mayor, and the report with the addition of the electric light was then carried.

Eastern Telegraph Company.—The revenue for the half year amounted to £372,852 10s., from which are deducted £102,499 7s. for the ordinary expenses, and £32,532 17s. 11d. for expenditure relating to repairs and renewals of cables, etc., during the half-year. After providing £3,263. 18s. 8d. for income tax, there remains a balance of £234,556. 6s. 5d., to which is added £62,942 4s. 4d. brought from the preceding half year, making a total available balance of £297,498 10s. 9d. From this balance there have been paid interest on debentures and debenture stock £27,801 6s. 3d.; dividend on preference shares, £20,174 1s. 8d.; an interim dividend of 2s. 6d. per share on the ordinary shares, £50,000—£98,365. 1s. 11d.—leaving a balance of £199,133 8s. 10d., from which £88,000 has been carried to general reserve fund. The Directors now recommend the declaration of a final dividend for the year ended March 31, 1893, of 2s. 6d. per share, and a bonus of 3s. per share, amounting together to £110,000, both payable on the 13th inst., free of income tax, and making, with the three previous payments on account, a total distribution of 13s. per share, or 6½ per cent. for the year on the ordinary shares.

Burton.—At the monthly meeting of the Burton Town Council, the Gas and Electric Committee, dealing with the electric lighting arrangements, advised that the charges for the new illuminant should be: for any amount up to 20 units, 10s. per quarter, and for every unit over 20, 6d. per unit—these prices to apply to ordinary customers otherwise than by agreement. In moving the adoption of the report, Alderman Lowe said they were making good progress with the electric light works, and the erection of the building was moving rapidly. The committee had carefully considered the question of charges for the use of the light, and by the Local Government Board regulations the maximum was 8d. per unit, while the minimum price was 5d., but the committee recommended a medium figure—viz., 6d.—feeling convinced that by placing the price at that reasonable sum they would receive a large number of applications. That would make the cost equal to that of gas at 5s. per 1,000 cubic feet. The report was adopted. The Finance Committee had to report that they had received the consent order of the Local Government Board, dated June 16, 1893, authorising the Town Council to create and issue stock for raising £131,641, of which £25,000 was for electric lighting.

Manchester.—Mr. Charles Nickson, superintendent of the Manchester Corporation Electric Light Department, issues a report stating that the central-station buildings are now completed, and the following plant has been fixed in position, viz.: Six steel boilers, steel tank, coaling stage and crane; steam-pipe, six 90-h.p. vertical compound engines, two 350-h.p. vertical compound engines, six dynamos giving 102 volts; two dynamos giving 410 volts; and two travelling cranes. The switch and instrument boards are in course of erection. Over a mile of concrete culvert for mains have been constructed, and about 65

tons of copper strip placed thereon upon porcelain insulators. Two and a half miles of cast iron pipes have been laid, into which six miles of ¾in. and five miles of ⅝in. insulated cable have been drawn. The works are rapidly approaching completion, and it is anticipated that a supply of current will be available by August 1. It appears that of a total authorised loan of £80,000 only £50,200 has yet been borrowed, of which £41,720 has been expended. No administration charges from the gas department are included, but there is £485 charged for engineer's advice. A proportion of administrative charges should be given for comparison with private company working.

Proposed Extension at Leeds. — Although the Yorkshire House to House Electricity Company's works in Whitehall road were opened so recently as May 10 last, the demand for the electric light in the city has proved so large as to necessitate an immediate increase of plant. It has been decided to put down another engine of 250 i.h.p., and a dynamo of corresponding capacity. It is anticipated that the additional plant will be ready for use in the coming winter. This addition, whilst involving an increase in capital expenditure of less than 10 per cent. (owing to the works having been constructed with a view to the allowing of easy and comparatively inexpensive additions), will increase the possible output of electricity no less than 40 per cent. It is expected that the profit earning capabilities of the company will increase in even greater proportion, the cost per unit of electricity naturally diminishing with every increase in production. The extension necessitates the raising of additional capital, and the directors are inviting subscriptions from the existing shareholders for the balance (2,634 shares) remaining unallotted of the first issue of 10,000 ordinary shares of £5 each. The directors hold more than one fifth of the total capital subscribed, and propose to increase their stake in the concern by at least £3,000.

Outing. — A brake outing of the employes of the Bath Electric Light Company and Messrs. Coward and Ihlee took place on Saturday, the place selected being Longleat. In the case of the first named firm it may be mentioned that this is the first outing given to the men since the works were started, and was the outcome of the zeal and interest displayed in the welfare of the men and works generally by the new engineer and manager, Mr. G. F. Metzger, who, in conjunction with Mr. F. C. Ihlee, suggested the idea of the two firms amalgamating for a day's outing. The visit to Longleat House was much enjoyed, and after lunch and sports the return journey was broken at Beckington for a social meeting. Mr. Metzger proposed the health of the directors, who had liberally contributed to the expenses. The toast of the evening was proposed by Mr. W. J. Sheppard, foreman of Messrs. Coward and Ihlee, who asked all present with him to drink success to the Bath Electric Light Company and to their new engineer and manager, Mr. Metzger, whom he was sure, with Mr. Wilson, were working very hard to make their lighting station second to none in the kingdom. Mr. Metzger responded, and in concluding desired all present in their employment to take an interest in this work, when he assured them success would sure to follow. He then proposed the firm of Messrs. Coward and Ihlee, to which Mr. F. C. Ihlee responded and trusted that all present had thoroughly enjoyed themselves. Bath was reached shortly after 11.

Accumulators for Nelson. — At the Nelson Town Council meeting last week the Gas Committee decided "that the tender of Mr. Thomas Barton for the supply of the K type No. 1 of cells made and supplied by the Electrical Power Storage Company, at £1,250, and to execute the necessary works required in conformity with the drawings and all the conditions and stipulations of the specification already issued, be accepted; the works to be completed within two months from date of order, the Electrical Power Storage Company to be responsible for the maintenance and repair of the accumulators for 12 months after fixing." Councillor Little complained that more information should have been given to members of the Council in reference to these electric accumulators than was contained in the minutes. A deputation had been paying a visit to London in reference to the accumulators, and he thought they might have supplied a printed report on the subject. Alderman Hartley said the matter had been before the full Gas Committee, which consisted of 12 members, and had been thoroughly discussed by them, a report having been supplied to them by the deputation of the information they had acquired in London. The resolution that had been passed was a resolution of the Gas Committee and another of the deputation, and was passed on the information supplied by the deputation. Councillor Little maintained that a report of some sort should have been presented to those members of the Council who were not on the Gas Committee, as it was a very important question. Alderman Hartley said any member of the Council could have a copy of the sub-committee's report, which contained all the information Councillor Little asked for. The minutes were passed. The Gas Committee have fixed the charge for a 50 c.p. electric lamp at £2. 10s. a year.

Morley (Yorks.). — At the Morley Town Council on Monday last week the Town Hall Committee presented their minutes as follows: "It was resolved that the Town Hall be lighted by electricity, and that a special committee be appointed to report as to the advisability of obtaining powers for the supply and of making arrangements for lighting the public lamps, and supply electricity to any private person. Mr. Henry Clarke reported that the building of the Town Hall was progressing, but not so fast as he wished. The contractor ought to be induced to set more men on, and thus provide work for the other branches of the trade." Councillor Rhodes said, in moving the confirmation of the minutes, that the committee were unanimous in the recommendation that the Town Hall should be lighted with electricity. Then there was the question as to whether they should put down a plant for the purpose of supplying ratepayers with a light that desired it. A special committee ought to be appointed to give the matter their fullest consideration, and to report as to what it would cost to light the town, and also the Town Hall separately. It was a matter of very great importance. Councillor Sykes said he would second the motion if the mover would leave out the portion "that the Town Hall be lighted by electricity," and add "such committee to report separately as to the cost of lighting the Town Hall and the town." Councillor Rhodes agreed. Alderman Dixon said before long their engines at Churwell would be of no value for pumping water, and it would be a question as to whether they would be of use in a scheme like that mentioned. He considered, however, that the question had come upon them hastily, and it wanted due consideration. Councillor Rhodes remarked that the engines would be of no use for this purpose. The minutes were adopted. The following were appointed a special committee to report on the matter: Aldermen Holton, Schofield, Clough, and Wilkinson; Councillors Rhodes, Scarth, Johnson, Jackson, Scholes, Hirst, and Craven.

Cork Tramways. — A deputation, consisting of the chairman (Mr. W. Roman, solicitor), Mr. J. W. Bourke, solicitor, Mr. R. U. F. Townsend, Mr. M. D. Daly, J.P., attended the meeting of the Cork Town Council on the 7th inst. with reference to the proposed tramway scheme for the city. The Standing Committee of June 7 had recommended that the use of overhead wires in connection with the propulsion of the proposed tramcars in the city by electricity should be sanctioned by Council, and the Council itself had already sanctioned the employment of electricity as a motive power, but on condition of the wires being laid underground. Mr. Farrington said that they should consider the matter well before they should take any action on it. If the wires were to be placed above the ground they might be an obstruction in many cases, such as interfering with the progress of fire escapes in case of fire. The Mayor said that no matter what the Council would decide on the subject the matter should have to go before the Board of Trade and receive their sanction. The Board of Trade would not consent to anything that might prove dangerous to the public safety or detrimental to the their interests. For his own part, he (the Mayor) was entirely in favour of the scheme. By it a large portion of the city would be block paved, and it would further save a great deal of expense. He thought the Council should not impede the company in any way in their project. Mr. Frazer said tramways similar to the proposed one in the city had been constructed in Bristol, Plymouth, and Edinburgh, and one also which extended for over 4,000 miles. The strength of the current of electricity in the proposed tramway system would be only 500 volts, and no danger whatever to the public would arise from it. Of course there had been accidents from time in such cases, but he felt confident that no danger would arise from the construction of tramcars in Cork. The recommendation of the Standing Committee that the wires should be placed overhead was passed unanimously, and Mr. Frazer having expressed his thanks, the deputation withdrew.

Manchester. — Sir J. Harwood, on the motion for the approval of the proceedings of the Gas Committee at the meeting of the Manchester City Council, said that one of the works of which he should be glad to be relieved was coming to a close. For many years he had had to do with the Bill which enabled the Corporation to deal with all companies who wanted to establish electric lighting stations in Manchester, and finally they obtained parliamentary powers to put down an installation themselves. He had been chairman of the committee which dealt with the matter, and he was happy to say that, all being well, next Friday week they would be able to light the gas offices in the Town Hall with electricity, and he was confident that the whole of the buildings would be so lighted during the autumn. For reasons which it would not now be prudent to state, the committee had been prevented from going on with the work in the Town Hall in the way they would very much have desired, but they were doing the best they could. He desired particularly to congratulate the Council upon having succeeded in putting down an installation second to none in the kingdom, and perhaps second to none in the world. They would be able in a fortnight or three weeks to begin supplying electricity over a very large part of the city. Many public buildings would, it was understood, be lighted by electricity. The committee were very much pleased with the efficient way in which the work had been carried out. The dynamos would be turned round this week, and the engines and everything connected with the installation were most beautiful. He wanted to say to the public that it was not intended that to any extent whatever the Corporation should supply fittings for buildings. They intended to supply electricity in the streets precisely in the same way and to the same extent as they supplied gas to-day. The only exception was in the matter of meters. The committee would supply meters. As regarded those meters he unhesitatingly said that they were very expensive and not satisfactory, and at any day they might be superseded by something that was satisfactory. They hoped the day was near when the scientific men who were trying to find a meter that would be much more reliable than those now in use would be successful. The minutes of the committee were passed.

Telephones and Electric Traction. — With the exception of those in the electrical industry, and interested parties generally, few people are aware, says the *Pall Mall Gazette*, what important issues are bound up in the report which Lord Cross's joint committee is now discussing in private. For years past the National Telephone Company, which works under license from the Post Office, has applied for the insertion in all Tramway Bills of a clause securing its lines against disturbance from earth leakage or elec-

trical induction in the event of electricity being used as a motive power for the tramways. The telephone is such an extremely delicate instrument and the system of earth return which the National Company still uses affords such facilities for disturbance, that the protection clauses, as worded, are claimed by many to have been almost prohibitive to the development of electric traction in England. It is between these two great interests—electric traction and the telephone—that the settlement really lies though the question has been complicated by other issues affecting the disturbance of railway signals, corrosion of water pipes, etc. If the committee appointed at the instance of the Board of Trade to decide upon the matter give their opinion in favour of the traction companies, a very marked change in the external conditions of our streets and cities may be looked for in a few years. Omitting all discussion as to the possible merits of different systems of electric traction, there is only one which at the present day has made its way to any large extent. This is the overhead trolley system, which is being worked on many hundreds of miles of road in America, and is being continually extended at an enormous rate. Two specimens only are to be seen in England—at Leeds and at Walsall respectively—in both of which places disturbances have arisen, either as regards the telephone company or the railway companies. But the general testimony of the public is so strongly in favour of lines of this class, which are clean, swift, and free from all the horrors of maimed and struggling animals which now disgrace our streets, that one cannot help but hope for a change in the legislation affecting electrical powers which shall make their introduction financially possible. With the impetus thus given to electric traction generally, there is little doubt that isolated vehicles of a more modern and graceful type would rapidly supersede the antiquated "growler" and the frisky hansom which pervade our streets.

Aberdeen Northern Co-operative Company.—A meeting of the shareholders of the Northern Co-operative Company was held last week at Aberdeen specially to consider the question of mechanical heating and electric lighting of the Company's central premises. The chairman (Mr. Jas. Doig) read the requisition of the 24 shareholders to consider these schemes which had been resolved upon by the directors, and which they (the signatories) "feared the expense would be rather heavy." After explaining the principles of mechanical heating, he concluded by saying that what he wanted to make out was that the matter had been fully considered by the committee, the Board, and professors on ventilation and electric lighting, and whether they could get a better elucidation of the matter at a general meeting attended by a good many people who did not know where the buildings were, what they were there for, or what required to be done, would be brought out before the meeting ended. Mr. Knight Forbes, convener of the Building Committee, having read the report of the Drapery and Buildings Joint Committee on the suggested alterations and improvements, the chairman read the report of the Buildings Committee on the question of the introduction of electric lighting, which bore that Prof. Kennedy, of London, estimated the cost of all the apparatus necessary for supplying 300 8-c.p. electric lamps, exclusive of wiring, at £625. In calculating the expenses of production, he allows 5 per cent. for interest, 5 per cent. for depreciation, £70 per annum for a mechanic, £32 for coal, £10 for oil, waste, and stores, and £30 for renewals and maintenance, altogether, £202. If to the above be added the cost of wiring which, according to the estimate of Messrs. Holmes and Co., Newcastle, would be £625, and allowing 5 per cent. for interest, and 5 per cent. for depreciation—the cost of production would be £264 or thereby per annum. The committee learned that the gas bill for the past 12 months was £204, and if the additional gas required at the new premises facing Gallowgate were added, which they estimated will amount to £92 (making altogether a gas bill for the central premises of £296), there would be a saving in favour of electric light of £32. Mr. Hunter, engineer (one of the directors), said that the Scottish Wholesale Society had introduced an installation of over 2,000 lights. If that society had seen their way to adopt electricity when gas was cheaper in Glasgow than in Aberdeen, he did not see why the Northern Co-operative Company should not do the same. Mr. William Milne, Victoria street, strongly opposed the introduction of electric lighting. Treasurer Bisset said that although every private individual could not manufacture electric light so cheaply as he could get it from the city, if the Co-operative Company took it in conjunction with their ventilation scheme, he was satisfied that they could manufacture a light better suited for their purpose than the gas they were at present supplied with. After some further discussion the meeting terminated.

Portsmouth.—At the Portsmouth Town Council last week, the Electric Lighting Committee submitted the tenders received for the electric lighting mains and the various fittings and accessories. Eight tenders in all had been received in time, and of these five provided for armoured cables for the high-tension mains and arc light conductors being laid direct in the ground, and a drawing-in system for the low tension mains, while the other three provided a drawing-in system for all the mains. The five tenders providing for armoured cables gave the following fixed prices: British Insulated Wire Company, £10,344; Silvertown Company, £10,385; Callender Company, £10,639; Siemens Bros. and Co., £10,706; W. T. Henley's Telegraph Works Company, £10,907. The three tenders providing for a drawing-in system were: International Electric Subway Company, £10,504; W. T. Glover and Co., £12,465. 7s. 8d.; Reid Bros., £12,498. Adding to these several sums the estimated cost of the fittings and accessories according to the schedule of prices in each tender, the amounts were as follows: On the first five tenders: British Insulated Wire Company, £11,673. 10s.; Callender Company, £12,537; Silvertown Company, £12,712; Siemens Bros., £13,407; W. T. Henley's Company, £14,579. On the other three tenders: International Electric Subway Company, £12,043; W. T. Glover and Co., £15,221. 7s. 8d.; Reid Bros., £15,244. After consideration the committee came to the conclusion that, looking at the small difference in cost, it would be better to provide for a drawing-in system for all the mains, as with this system it would scarcely ever be necessary to reopen the roads or footways after the cables had been once laid, and the committee therefore recommended that the tender of the International Electric Subway Company be accepted at the fixed price, and that the committee be authorised to order the fittings and accessories under the contract at their schedule of prices. Under the contract with Messrs. Yates and Thom, and S. Z. de Ferranti, Limited, there was a schedule of prices for transformers and other fittings, and the committee recommended that they be authorised to give orders under this schedule to the extent of £3,000. The committee recommended that a certificate from the engineers for £500 in favour of Mr. T. W. Quick in respect to the electric light station be paid; and also that the common seal be affixed to the contracts with Messrs. Yates and Thom, and S. Z. de Ferranti, Limited, and Messrs. C. A. Parsons and Co. for the supply of electrical plant. Alderman Ellis, in moving the adoption of the first clause, announced that the International Electric Subway Company's tender had been altered to £12,000, and their tender, including all accessories, from £12,043 to £13,539. That day the committee had arrived at the last contract for completing the installation entrusted to their care, and notwithstanding the fact that they had procured the best possible machinery of the most improved make, and including the cost of the mains, the total amount would be considerably less than the estimated sum. Mr. Ross seconded. Mr. Light thought that as the first tender of the International Company was wrong, it should be thrown out. Alderman Scott Foster said that the committee were satisfied that the mistake was *bonâ fide*, a lump sum of £3,000 for excavations having been inadvertently omitted. He dwelt upon the superiority of the subway system over that of iron pipes, and while admitting that it was inconvenient to have to amend a tender, pointed out that under existing circumstances it would be advantageous to the Council to act in accordance with the proposal of the chairman of the committee. Ultimately the report was agreed to.

St. Albans.—At the meeting of the St. Albans City Council, Mr. Toulmin moved "That it is expedient that the city be lighted by electricity, and that a committee be appointed to consider and report what steps should be taken for carrying out the work." In bringing the resolution before the Corporation, Councillor Toulmin said that by the courtesy of Mr. Longmore, the town clerk of Hertford, he had been supplied with an excellent report of a committee which had been appointed by the Corporation there to consider this matter. A capable engineer had been consulted by that committee, and they reported that they were thoroughly convinced of the advantages of electrical energy for lighting purposes, and they had no hesitation in recommending the Corporation to embark upon this undertaking—that of supplying electric light to the town—as they felt sure it would prove to be a paying concern, and a source of considerable income to the borough. They also reminded the Corporation that electric lighting was no longer in its infancy, but it had been tried and found successful in many places. Continuing his remarks, Councillor Toulmin said that, looking at the estimate of the cost of lighting the streets this year, he found it was £940, and that seemed to him to be a considerable sum. He believed that if they went systematically to work, and picked the brains of other authorities and profited by the experience of other towns, they would be able to carry this out in such a way as to reflect considerable credit on the town and materially benefit the residents. It was well worth making an effort to obtain the advantages which resulted from an installation of the electric light. There were many facts and figures which he was prepared to bring before the Council, but he would not trouble them that evening. He proposed, therefore, that the Mayor, Alderman Miskin, Councillors Rowden, Bennett, Hurlock, Hitchcock, and Gibson be appointed a committee to consider and report on the subject. Mr. H. P. Smith seconded. Mr. Barnard objected to such an important subject being brought forward, as this had been, at a monthly meeting, without having previously been considered in committee. His opinion was that this subject should first have been brought before the Urban Sanitary Committee. He proposed as an amendment that this matter should be referred to that committee. He thought that they should proceed very carefully, particularly when it was remembered how great a failure had been the attempt to light Barnet by electricity. Mr. Hurlock thought the work ought to be done by a private company. Mr. Smith said he quite agreed that the time had not arrived for St. Albans to be lighted by electricity, but he did take strong exception to the statement that it should be left to a private company to step in and supply electric light to the city. When electric light came down to the price of gas, the Council would be bound to take it up. He wished that former corporations had been more enterprising, as if they had been the water supply and gasworks would be in the hands of the Corporation, and the profits arising from them would have paid half the rates. They must see that when the time arrived a private company did not step in, and the profits, as in the case of the waterworks, go to those who resided outside the city. The waterworks and gasworks ought to belong to the ratepayers, who should profit by the receipts. He was certainly in favour of a committee being appointed, as proposed by Councillor Toulmin, to enquire and not to act, because if were proposed to do anything definite beyond obtaining information, he should not have agreed to the appointment of the committee. After further discussion, the resolution

was carried in an amended form, and the Council then went into committee.

Torquay. —Mr. W. H. Trentham, electrical engineer, of Bristol, has been engaged by the Torquay Town Council to inspect the town and report on the ways and means of lighting it by electricity. In his report to the Council he advises the adoption of the Bath Saloons as the site of the central station. There no expense would be necessary for buildings, saving the town £3,000 or £200 a year. To avoid the smoke nuisance he suggests that gas should be used, or that the boilers should be fired by gas generated in a regenerative furnace. After careful enquiries, Mr. Trentham has come to the conclusion that 1,500 lamps of 16 c.p. would be taken up immediately the current was available. This estimate is independent of the hotels, which he thinks would certainly require not less than another 1,000 16 c.p. lamps. His advice is that provision in the first instance should be made for 3,000 lamps of the power indicated. These would require about 420 i.h.p., which might be advantageously divided between three engines, each indicating 120 h.p., and one small engine of 60 h.p. Owing to the length of the streets (5,500 yards), a low pressure system would be unsuitable. He estimated that high pressure mains, including low pressure connecting mains between the transformers, would cost about £5,000, while the cost of low pressure network and feeders, allowing the usual losses, would be about £15,000. If the Bath Saloon site was adopted as the central site, he recommends the employment of steam engines for the heavy work between dusk and 10 p.m., and a 60 h.p. gas engine for the remainder of 24 hours. The approximate cost of steam plant, with gas engine for day lighting, would be £17,403; and of maintenance £3,100. While making provision for street lighting, Mr. Trentham says there could be no object in altering the present mode of illumination generally. He proposes that 16 arc lamps be provided, one being at the top of Lower Union street, another outside the Town Hall, one at the corner of Abbey place and Fleet street, two at Ellacombe Green and Market Corner respectively, five in new Pleasure Gardens, and the remainder distributed between Beacon Hill, Victoria parade, Torwood street, and the Strand. These lamps would cost £20 each, or £320 per annum, and would displace about £45 gas lamps costing about £225 a year, and giving some 1,130 c.p. against 11,000 c.p. given by the arc lamps. The revenue per annum, taking the current at 6d. per unit, and including £320 for the arc lamps, would be about £3,320; at 7d., £3,829; at 8d., £4,320, not allowing for any revenue from meters and motors, cooking apparatus, etc. The electric current at 6d. per unit is approximately at the same rate as gas at 4s. 5d. per 1,000ft.; but in practice it is found so easy to economise the light by at once turning it out when not required, that the price in actual use is practically equal to gas at 3s. per 1,000ft. Mr. Trentham suggests, however, that the price be fixed at first at 7d. per unit (equal to 3s. 6d. per 1,000 for gas), and that discounts be allowed according to the number of hours the light has been in use. He adds to his report: "It is probably hardly necessary for me to urge strongly the advisability of the Council carrying out this work and retaining their powers in the face of the monopoly enjoyed by gas companies. Electric lighting will pay its way from the commencement, and afterwards prove a very important source of revenue." He advises the Council to on no account transfer their provisional order, whether it is decided to carry out the installation at once or not.

Aberdeen.—Very satisfactory progress is being made with the preliminary work in connection with the electric lighting, says the Aberdeen paper. Some little time ago we chronicled the commencement of operations for the erection of the generating station in Cotton street, whence the supply of electricity will be distributed over the city. At present the walls of the buildings are 4ft. or 5ft. above ground; with dry, open weather rapid progress with the work may be expected. While this has been going on in connection with the buildings, a commencement has also been made with the laying of the copper mains for conveying the electricity through the streets. The pavement has been opened from the station in Cotton street along Castle terrace, and the mains—enclosed in a watertight concrete culvert—have been laid half way along the terrace. So far, attention has been directed to the laying of mains for the supply of the incandescent light only for private lighting; at a meeting of the Gas Committee of the Town Council, a proposal was brought forward with reference to the supply of electricity for the arc light in view of the lighting of the streets also. Treasurer Bisset suggested that advantage might be taken of the opening of the pavements to lay a pipe with a cable in view of the lighting of the streets by the arc system. The suggestion was generally approved by the committee, and it was resolved to approach the Council on an early date for authority to proceed with the work. Should the desired authority be given, Prof. Kennedy will, in all probability, again visit Aberdeen and report upon the scheme. As indicated, the scheme which is at present in progress is for private lighting alone—that is, for the supply of light and power, if required, to houses, shops, etc., along the line of the mains, in the same way that gas is now supplied. The area through which mains are to be laid at present is the central part of the city, comprising Castle and Union streets, Union terrace, the Viaduct, School hill, St. Nicholas street, Broad street, Market street, and part of the quay. At some future date the mains will be extended to the western part of the city. The system is a low tension one and the current is carried, whenever possible, by bare copper strips laid on porcelain insulators set in a concrete trough or culvert. The culvert will in all cases be under the pavement; where it is necessary to go into the road, and at all street crossings, insulated cable is to be used, drawn into cast-iron pipes. Brick inspection boxes will be built in the pavement to enable all joints to be made and inspected, and to take off the services to the houses. The boxes will be closed by a cast-iron top, faced with cement. The generating station in Cotton street forms part of the gasworks. The engine and boiler rooms are on the ground level, and the battery-room is above the engine-room. In the boiler-room are to be four boilers arranged to burn gas coke. In the engine-room are five high speed steam engines, three of 80 h.p. each, and two of 40 h.p., each driving a dynamo direct, without ropes or belts. The switchboard, by which the regulation and distribution of the current are carried out, is in the engine-room, and is arranged so that the engineer in charge has full control of the system. The engine-room is large enough to admit of a large increase of the supply over that now contemplated, and the arrangement of pipes and machinery is such that the chance of any stoppage of the supply by breakdown is reduced to a minimum. The buildings for the station have been designed by Mr. Alexander Smith, the superintendent of the gas department. The Electric Construction Corporation of Wolverhampton are the contractors for the machinery in the station, Messrs. Siemens Bros. for the switchboard, and Messrs. Scott and Sellar, of Aberdeen, are now carrying out the work of laying the main.

The Blackpool Tramway.—In the minutes of the Blackpool Electric Lighting Committee of June 23 was a resolution to the effect that Mr. John Hesketh, borough electrical engineer, be relieved from the traffic management of the tramways; that Mr. John Lancaster be appointed traffic manager; and that Mr. Hesketh be desired to retain the control of the electric arrangements connected with the tramways, and of the book-keeping as at present outside the treasurer's department. At the Town Council meeting when this was discussed, Mr. Bibby said he should like to know if Mr. Hesketh was going to retain the £50 which had been paid to him for the management of the tramway. He moved that the resolution be referred back for further consideration. Mr. Pearson said the committee had gone into the whole of the circumstances connected with the alteration proposed. It was a very delicate point to raise in Council. Mr. Hesketh had had control of the electrical arrangements, and had also acted as traffic manager. There was no alteration proposed except that Mr. Lancaster should be made responsible for the conduct of the traffic, thereby relieving Mr. Hesketh. The Council voted him £50 for doing the work temporarily. Mr. Bibby said if Mr. Lancaster had the additional responsibility he ought to have a certain proportion of the payment. Mr. Mather agreed. Mr. Parkinson, in rectifying one or two mis-statements which had, he believed, been made through ignorance, remarked that at present it was impossible for any man to work the trams satisfactorily. If they thought £50 more than paid for the work Mr. Hesketh did they did not know the value of labour. He anticipated that a division of the work would cause confusion. They had better maintain the present system until the summer was over and then spend £4,000 or £5,000 on a system which could be used satisfactorily. If they did not give full facilities for carrying out work, they could blame nobody. Mr. Councillor Pearson considered that Mr. Hesketh's duties had multiplied so as to make it absolutely necessary to relieve him from the management. The receipts showed a net increase of something like £400 up to the last meeting upon the previous year's work, but as no alteration in the system could be made before the end of the season complaints would be general for some time to come. In reference to the above it is interesting to give the original discussion on this appointment in December, 1892. Extract from the electric lighting and tramway minutes: "'That a sum of £50 be allowed to Mr. Hesketh, as the general manager of the Blackpool tramways for the period from the 9th of September, 1892, to the 9th of September, 1893.' Mr. Councillor Bickerstaffe called attention to the sum of £50 recommended to be given to Mr. John Hesketh for managing the electric tramways. In his opinion something ought to be shown as to the result of the working of the trams before they started to increase salaries. The Mayor said that Mr. Hesketh was asked to take over the management of the trams but although it was not provided at the time that he should have any remuneration, it was thought that he should be paid extra. The payment of £50 was for his services as manager of the tramways for one year, to date from September last. He thought that this was little enough payment for the extra work Mr. Hesketh had done. Mr. Alderman Bickerstaffe said that subsequent to the appointment of Mr. Hesketh as electrical engineer, the Corporation bought the tramways and required a general manager. They considered that they could not have a better man than Mr. Hesketh, and they therefore appointed him their general manager. When he told them that the general manager of the old company received £150 per year, and when they considered that Mr. Hesketh had only £50 per year for the same duties, surely they would not say that the Corporation was paying too much for the work. This was not an increase of salary, but merely payment for extra work outside his duties as electrical engineer, etc."

Richmond (Surrey).—The following report was presented to the Richmond Town Council meeting by the Electric Lighting Committee: "Mr. Shoolbred's account has been thoroughly gone into by the committee, with the result that the town clerk has been instructed to write Mr. Shoolbred to say that after having carefully examined his account and the resolution relating to his appointment, they are prepared to recommend the Council to pay him the sum of 100 guineas, the committee being of opinion that this sum is fully equal to what he would be entitled to receive under the arrangement come to. The committee further report

that the chairman and town clerk had an interview with Prof Kennedy, and suggested his accepting the appointment of consulting engineer to the Council should the appointment be offered to him by the Council. He, however, expressed his regret at being unable by reason of his other engagements to undertake further duties The committee have since been in communication with Messrs Urquhart and Small, electrical engineers, of Victoria street, Westminster, and have had an interview with Mr. Small, of that firm, who is a resident in Richmond, and having regard to the fact that they have carried out considerable works under Prof Kennedy at Dundee, the committee beg to report that Messrs Urquhart and Small have offered to undertake the duties of electrical engineers to the Corporation by letter dated June 30, on the following terms: 'We undertake to examine all the plans and drawings submitted to the Corporation for approval by the electric lighting contractors, and to advise the Corporation on such plans, and, when required, to prepare and submit revised plans We undertake to superintend the laying of the mains and the construction of the junction and other street boxes, on behalf of the Corporation, so as to ensure that this work is carried out in a substantial and lasting manner. We undertake to examine and test the works executed, and the plant erected by the contractors, when completed, and to report to the Corporation on the same. We undertake to attend to and advise the Corporation with reference to the serving of all statutory notices relating to the Richmond provisional electric lighting order, to report to the Corporation from time to time, and to attend the meetings of the Electric Lighting Committee of the Corporation when required Our fee for the above work, from the date of our appointment up to the date of handing in our report on the works when completed, will be one hundred guineas, which will include all travelling and incidental expenses.' The committee recommend the appointment of Messrs Urquhart and Small as electrical engineers to the Corporation on the above terms." Upon the motion of Councillor Heasler it was resolved that the recommendation of a former report not yet dealt with, that Mr. Shoolbred's resignation should be accepted, was agreed to. Councillor Heasler said that he would not go into the question of Mr. Shoolbred's accounts on that occasion, but he moved the recommendation as to the appointment of Messrs. Urquhart and Small, which he thought was a very satisfactory one. This was agreed to. Councillor Heasler said that the works were now progressing more satisfactorily. The clerk read two letters relative to the sudden disappearance of the electric light during the progress of the last meeting, the first from Mr A. M. Smyth, resident engineer, Richmond electric light station: "Having reported to Messrs Latimer Clark, Muirhead, and Co. that the lights in the Town Hall went out on Tuesday, the 4th, about 9.30 p.m., I have been requested to draw your attention to the cause, which was due to the burning out of the main fuse situated in a locked cellar in the building. This fuse was not put in by us, as our own responsibility ceases at the terminals which connect our mains to the building" The second, from the contractors, Messrs. Strode and Co., explained that the fuses they had put in were capable of carrying 200 amperes at 100 volts, and they think there is no doubt that the reason they suddenly fused must have been owing to an increased pressure on the company's side, as none of the section fuses went throughout the building which protect the small circuit, but only the main fuses Councillor Dimbleby suggested that the letters should be referred to the Works Committee to see if there was anything wrong with the installation. Alderman Robinson thought it would be better for the matter to go to the Electric Lighting Committee. Councillor Dimbleby's proposition was accepted.

PROVISIONAL PATENTS, 1893.

JULY 3.

12971. **Improvements in alternating-current motors.** Olof Dahl and Simeon Lee Phillips, 34, Southampton buildings, Chancery lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, 8th December, 1892, being date of application in United States.) (Complete specification.)

12981. **Improvements in signal, telegraph, or other posts.** Illius Augustus Timmis, 2, Great George-street, Westminster, London.

JULY 4.

13024. **Improvements in instruments for measuring and indicating electrical energy, and for other measurements.** George Cheffey James, Bank buildings, George street, Sheffield.

13064. **Improvements in devices for prevention of retardation in electric cables.** Silvanus Philips Thompson, 323, High Holborn, London.

13066. **Improvements in or relating to the manufacture of incandescent mantles or filaments for use in connection with gas or electric incandescent lamps** Alfred Julius Boult, 323, High Holborn, London (Otto Hermann Steuer, Germany.) (Complete specification.)

13081. **Improvements in the construction of plates for secondary batteries.** James Pitkin, 6, Bream's buildings, Chancery-lane, London.

JULY 5.

13111. **Improved traverse motion of the commutator and armatures of dynamos and electric motors.** John Pease, Valley Mills, Apperley Bridge, Yorkshire.

13101. **Improvements in the method of winding for dynamo-motors for balancing a three-wire system of electrical distribution.** David Urquhart, 17, Victoria street, Westminster, London

13133. **An improved automatic electromagnet switch.** James Hardie McLean, 20, High Holborn, London.

JULY 6

13203 **Improvements in electric traction and apparatus therefor** David Cook, 28, Southampton buildings, Chancery lane, London.

13217. **Improvements in secondary electric batteries** The Lithanode and General Electric Company, Limited, and Job Thomas Niblett, 47, Lincoln's inn fields, London.

13218. **Improvements in plates or elements for secondary electric batteries.** The Lithanode and General Electric Company, Limited, and Job Thomas Niblett, 47, Lincoln's-inn fields, London.

JULY 7.

13263 **Electric apparatus for operating dental implements.** Charles Arthur Allison, 52, Chancery lane, London. (Oscar Henry Pieper and John Henry Harbour, United States

13274. **Improvements in the manufacture of plates for electric accumulators.** Constant Rousseau, 4, South street, Finsbury, London

13276. **Improvements in and relating to electric arc lamps.** Edmund Jokl and Carl Holzapfel, 45, Southampton buildings, Chancery lane, London.

13279 **Improvements in ear-pieces for telephones** Rudolf Seiffert, 45, Southampton buildings, Chancery-lane, London. (Complete specification.)

JULY 8.

13336. **Improvements in the electrolytical production of nickel and other metals.** Carl Hoepfner, 45, Southampton-buildings, Chancery lane, London

13339. **An improved manufacture of carbon for electrical purposes** Henry Harris Lake, 45 Southampton buildings, Chancery lane, London (Adam Charles Girard and Ernest Auguste Georges Street, France.)

13340. **Improvements in and relating to electric furnaces** Henry Harris Lake, 45 Southampton buildings, Chancery-lane, London (Adam Charles Girard and Ernest Auguste Georges Street, France.

13341. **Improvements in transforming electrical energy of high tension into low tension and in apparatus therefor** Reginn Niewerth, 1, Quality court, Chancery lane, London.

SPECIFICATIONS PUBLISHED

1892.

9108. **Electric batteries.** Shrewsbury and Dobell
10999 **Electric clocks** Webber.
11194 **High-tension circuits.** Drake and Gorham.
11822 **Driving clocks, etc., electrically.** Aron.
13381. **Electrical storage plates.** Bright and Mercier.
14160. **Electrically working the gear of guns** Grimston
14250. **Secondary batteries.** Rosenthal and Doubleday.
14674. **Electric telephonic apparatus.** Marr.
16545. **Galvanic batteries.** Ball.

1893.

4368. **Electric arc lamps.** Ward.
6559. **Electric heating apparatus.** Dewey.
6885 **Electric railways.** Lake. (Cattori)
7389 **Electrically welding metals.** Thompson. (Coffin.)
8808. **Electric accumulators.** Lehmann.
9552 **Microphones and telephones.** Paetzold.
9818 **Electrical conductors.** Cummings.

NOTES.

Historical Collection Lost.—The ship containing Prof. Ferraris's collection of apparatus *en route* for Chicago, was sunk in the harbour of Genoa.

Manchester.—The important event of turning on the electric light from the Corporation mains to the city of Manchester took place informally last week.

Gilgit Telegraph.—Satisfactory reports have reached Simla of the progress made in laying the new telegraph from Srinagar to Gilgit. The line is being rapidly carried forward.

Fire at Manchester.—It is stated that the fire at the Manchester Reference Library, which caused damage to 10,000 volumes, resulted from the careless use of candles in the dome by the men who were fitting electric light wires.

Coast Communication.—The second congress of the International Maritime Congress was opened on Tuesday at the Institution of Civil Engineers. A discussion was held on "Communication between Lightships and the Shore."

Accumulator Literature. — A corrected list of articles giving the description of all types of accumulators, is given in the *Electrical World* of July 1. It contains exact references to several hundred articles in the electro-technical papers.

Death of an Electrician.—The death is announced of M. Marie Davy, the electrician and astronomer. He died on Sunday at Clamecy, Nièvre, at the age of 77. He is best remembered in the electrical world by the cell which bears his name.

Lightning among Telephones.—A considerable proportion of the telephone trunk line between Cupar and St. Andrews was destroyed by the lightning on Sunday, and some of the instruments in the St. Andrews exchange were rendered useless.

Watertight Doors.—The suggestion is made that in case of sudden disaster, such as that which overtook the "Victoria," an arrangement for the simultaneous closing of watertight doors controlled electrically from the deck, would prove most useful.

French Engineers at Chicago.—The Municipal Council of Paris has voted 3,000f. for the chief engineer of lighting and highways to visit Chicago and report upon the exhibition in general, and America in particular, as to lighting and electric traction.

Attraction of Vacuum Tubes. — Sir David Salomons has found that vacuum tubes when lighted have a greater attraction together than is accounted for by the current passing or the static effect. A spiral tube sucks like a solenoid: no repulsion takes place.

Heilmann Locomotive.—In a trial at Havre with the Heilmann locomotive, with the motors connected to a temporary axle, it was found that under proper test conditions a rotation equivalent to 120 kilometres per hour could be obtained, and without noticeable vibration.

Night Photography.—Mr. Mitchell, an enterprising photographer at Blackpool, has taken a photograph at Blackpool—when the tower was illuminated for the Royal wedding—at night, the plate being exposed for an hour and 10 minutes. The tower is well defined, and the electric light came out a mass of white. As a specimen of night photography the plate is very interesting.

Telegraphy on the Paris Telephone Line.—Some experiments have been made during the last month on the Paris-London telephone line to ascertain the practicability of telegraphing along the line without interfering with its telephonic properties. Several methods have been tried, some with good result. It is expected a trial in practice will be made on one of the wires.

Incandescent Lamp Manufacture.—The transformation of silk or cotton thread into carbon filament for lamps is carried out usually in two processes—the parchmentisation of the thread and the carbonisation in a mould. Mr. Pope simplifies the operation by covering the thread with a coating of paraffin, by immersion in a bath of this hydrocarbon under considerable pressure. When the paraffin has penetrated thoroughly, the filament is at once carbonised.

Battery Traction.—The *Mechanical World* this present week contains a letter from Mr. Epstein on accumulator traction, emphasising the fact that his batteries have run 6,000 miles at Birmingham without renewals. Maintenance at 1½d. per mile means £37 earned, and the cost of renewals as known to the company is £19, leaving ¾d. per car mile profit. It is objected, however, that Mr. Carruthers-Wain has not yet vouched for the financial success of the running of battery cars at Birmingham.

Trolley Patents.—Considerable attention is being at last given in America to Benson Bidwell, one of the earliest workers in electric traction. Mr. Bidwell ran his electric car in Philadelphia and Boston in 1884 and 1885, and patents were issued to him in 1885 and 1887 for the under-contact pivot-jointed trolley, which is now universally used. Suits have been entered to test the legality of the Bidwell patents, which, if upheld, will control as important interests as the incandescent lamp patents.

Apartment Houses.—The first of the great "apartment houses" in New York was that erected by Mr. Rutherford Stuyvesant, near Third - avenue, in 1870. Mr. Everett Blanke, in an article entitled "The Cliff-Dwellers of New York," in the *Cosmopolitan*, estimates the present number of these immense buildings in that city at 700. Nearly all are provided with electrical and steam appliances, requiring the outlay of so much capital and attention as are rarely found even in the private dwellings of American millionaires.

Patin Flywheel Dynamos.—M. F. Desquiens, in the *Génie Civil*, describes the new types of machines recently brought out by M. Patin. These are alternate-current dynamos attached as flywheels to an horizontal engine, making a sound engineering job. Alternate-current motors are also made by M. Patin, whose researches, in conjunction with M. Levavasseur, have solved, it is stated, the problem of alternate-current transmission. The Patin alternate-current motors are adapted for either high or low pressure, and are made for high or low speeds.

Telephony.—We are informed that, with the assistance of Mr. Arthur J. Stubbs, Mr. W. H. Preece, F.R.S., has just finished the preparation of "A Manual of Telephony," which will be published early next month by Messrs Whittaker and Co. The authors have unusual opportunities for obtaining accurate information on technical details connected with their subject, and the 500 pages of the new book will doubtless be a veritable mine of information for all who are interested in telephonic matters. An important feature in the work is the large number of specially drawn diagrams.

Inventions Wanted.—The dynamo is nearly perfect. It returns 95 or 96 per cent., but even it might do without

a commutator, or do with a simpler one. The whole dynamo requires "mechanicalising," so to speak, still more. One well-known mechanical engineer once expressed himself in a dynamo-room: "I never see a dynamo armature but I think of a bundle of wires as a stick." But if the dynamo were perfect, there are other worlds to conquer. The incandescent light uses about ½ per cent. of the energy of the coal usefully. How can we save the other 99 per cent.? Here is the one great question still before electrical engineers.

Books Received.—We have received "Captain Enderis—First West African Regiment," a novel by Archer P. Crouch, author of "On the Surf-Bound Coast," etc.; two volumes; published by Messrs. W. H. Allen and Co.; 21s. We have before us also a second edition, revised, with large additions, of "Electric Light Fittings—a Handbook for Working Electrical Engineers," by John W. Urquhart (Crosby Lockwood and Co.). Chapters on street cable work, specifications, fire risks are added, and the lighting of ships is extended by a description of the installation on the "City of New York," Inman liner, by Mr. Chas. H. Peters, electrician on that vessel.

Edinburgh Royal Society.—At the last ordinary meeting of the Royal Society of Edinburgh for the present session, held last Monday, Prof. Sir Douglas Maclagan, M.D., president, in the chair, Prof. C. G. Knott explained a method of estimating magnetic induction in iron. He said that however it might vary, it appeared that whether in the case of a solid bar or a tube the total induction was exactly the same in small fields, consequently he inferred that induction was largely a superficial phenomenon in low fields. But as the field was made stronger induction became less and less superficial, and passed, as it were, into the tube. Prof. Tait, on behalf of Mr. G. Romanes, explained a method of attraction by graphic process.

Metric System.—"Engineers here," says an English engineer in Brazil, "will not take the trouble to convert our hodge-podge mixture of weights and measures into the metrical system. They do not understand them, and have no basis of comparison with Belgian and French goods. Brazilians like English goods: believe them best and cheapest in the long run, but find it impossible to estimate from your measures." English engineers must submit to use the metric system, at any rate for countries speaking the Latin tongues—this becomes more and more evident every year. The Sheffield trades use one or the other indiscriminately, and the steel-rolling lists are always made on the two systems of measure. Why cannot electrical engineers do likewise at once?

The Poor Man's Power.—Mr. Preece has given it as his opinion that electricity will eventually provide the poor man's light. The electric motor is destined to be the poor mechanic's friend. Its management and control is simple, its service is in direct and immediate command, it requires no licensed engineer or fuel, and in economy of space occupied has no competitor. In some instances where needed for intermittent use, power can be furnished at one-tenth to one-fifth of the cost of steam. The electric motor (says the *Age of Steel*) "has found its way into plumbing, metal spinning and machine shops in New York, and as an economic factor, with the other advantages named, there can be no grave question as to its more general adoption. We predict the renting of electric power to yet become a remunerative and general enterprise."

South Staffordshire Tramways.—During the meeting of the Municipal Engineers last week at West Bromwich, a visit was paid to the generating station of the electrical section of this tramway system. The tramway company had placed at the disposal of the institute steam trams from the Town Hall, West Bromwich, to the commencement of the electrical section, whence the trip to the generating station was made on the electric cars. Mr. A. Dickenson, C.E., J.P., met the members at the station and explained the apparatus. His paper read before the Tramways Institute on December 30, 1892 (reported in the *Electrical Engineer* of January 6, 1893), was distributed to the members. An illustrated description of the system will be found in our issues of November 11 and 18 of last year. So far as we could judge or hear of the running of the cars, the work is carried on in an excellent manner.

Junior Engineering Society.—Recent visits of this society have been to the Deptford station of the London Electric Supply Corporation and to the Blackwall Tunnel works, both occasions being largely attended. At Deptford the members were shown over by Mr. Brown, who fully explained the arrangement and working of the plant and pointed out the numerous features of interest. On behalf of the contractors, Messrs. Pearson and Sons, the party were received at Blackwall by Mr. E. H. Tabor and Mr. L'Estrange, under whose guidance the works on the north side were first inspected. The members then proceeded across the river to Greenwich, and after being shown the work at surface, descended one of the caissons and passed to the working face where the cutting shield was seen in operation driving the tunnel. At the conclusion of the visits the thanks of the members for the attention received were expressed by the chairman, Mr. Sidney Boulding, M.I.M.E.

Polyphase Currents in Spain.—The two neighbouring towns of Elgoibar and Eibar, in Spain, will shortly have installations of polyphase-current plant for light and power. The work is being carried out by Messrs. Siemens and Halske, using the power of the River Deva, which, with about 30ft. fall, gives 300 available horse-power. Hercules turbines are used at 200 revolutions, driving a 80-kilowatt "Drehstrom" dynamo. The current generated at 120 volts will be transformed up to 5,000 volts, and conducted by overhead wires on oil insulators to the two towns situated one and three miles distant respectively. About 60 incandescent lamps will be used in the street-lighting in Elgoibar, and several hundred private lights. In Eibar, an industrial town, 120 lamps will be required for street-lighting, and 400 lamps for private lighting are ordered. Electromotors of from 1 h.p. to 25 h.p. will be installed for transmission of power. Don Ermanno Schilling is the Madrid agent who has carried out the details of this installation.

Physiological Effects.—According to Dr. Stéphane Leduc, professor at the School of Medicine at Nantes, the alternate currents obtained with electrostatic machines have physiological properties very different to those attributed hitherto to currents of high pressure and great frequency. If the ball terminals of the conductors are grasped in the hands, nothing is felt if the exciters give a continuous series of sparks; but if the current is localised on the skin by means of a blunt point, as soon as the point passes over a sensor or motor nerve the nerve is excited in all its distribution below the electrode; the impression provoked in the sensor nerves enables the limitation of their distribution to be exactly mapped out, and the least displacement of the electrode on the surface of the skin immediately causes all sensation to cease. These currents, therefore, enable the nervous excitation to be localised much more accurately than has been possible hitherto, and this property makes it likely that such currents will prove useful to physiologists.

The Lenzie Merchant and the Telephone.—"One good merchant in Lenzie," says an amusing account in the *Glasgow News*, "has been astonished by his telephone. A few days ago he heard a loud report, proceeding, apparently, from one of his shelves, on which were stacked a number of whisky bottles wrapped in the customary tissue paper. He then saw these filmy envelopes burst into flame, and the woodwork had begun to singe before he could get the flames extinguished. On examination, he found that the telephone wire, which was conducted behind the shelving, was severed, and that each end was fused. As this happened while a heavy thunderstorm was being experienced at a little distance off, the conclusion arrived at is that the wire had been struck by lightning, and that the current, being too strong for the wire to conduct, had 'bust' things in general—that is not scientific, but it is near enough. The instruments and wire have been put to rights now. But ever since, when that merchant has had occasion to handle the receiver he caresses it with all the bashful timidity of the kiss of sweet seventeen." The incident, it must be admitted, is very well described.

Postal Telegraphs Illuminations.—Want of space in our last issue compelled us to hold over reference to this matter. Amongst the many beautiful illumination effects that were to be seen in the streets of London on the evening of the Royal wedding day, July 6, that exhibited on the huge building of the Postal Telegraphs merits notice. Starting at the corner facing the top of Cheapside, two horizontal lines of lights travelled along the building, illuminating the whole length of that side forming part of Newgate-street and half-way along the frontage of the building. The lower line was positioned on a level with the first floor, and the other marked out the top of the building. At the Cheapside corner was a design consisting of the letter "M" placed within the letter "G," whilst two sheafs sprung up from below, encircling the monogram. Over the portico, in the front part of the building, was placed a crown having the letter "V" on the left and the letter "R" on the right. The entire designs were made by incandescent lamps of 16 c.p., and altogether about 1,300 electric lamps were used, which were run off the dynamos that supply the electric light to the General Post Office. The illuminations were on Friday and Saturday evenings following, and caused admiring crowds to assemble near the General Post Office buildings. The work was only commenced late on Monday afternoon and the whole was ready by Thursday afternoon, a very small staff of men being at it—a smart piece of work for such a short time. We understand that the entire expense has been met by private disbursements on the part of those interested. We must compliment Mr. Probert, the superintendent of the electric light department, on the unqualified success attained, and the expeditious manner in which the work was accomplished.

Technical Education.—In view of the importance of the subject of electrical engineering and of the large increase in the number of students in section, the governors of the Merchant Venturers' School at Bristol have decided to materially improve the equipment of this department. For this purpose a complete installation will be provided. It includes two small dynamos of different types, built by the students of the school, and a large four-pole experimental dynamo, specially built by the Brush Electrical Engineering Company. The latter has its field-magnet coils so wound that it can be used as a series, shunt, or compound wound machine; it is also provided with a special exploring coil in the armature, so that magnetisation of the armature can be examined, and the machine is so constructed that an alternating current of slow periodicity can be obtained. These three dynamos will be driven by a horizontal gas-engine, and will be used for experimental purposes, and also for charging a set of electric power storage batteries placed in the electrical laboratory; from these cells currents will be conveyed to the lecture theatre and to the laboratory tables. During the past few weeks the senior students in the electrical engineering section of the school have been busily engaged in placing the necessary cables and wires throughout the building, and the whole will be in readiness for use during the ensuing winter session. The senior students will in turn be placed in charge of the installation, and will thus have ample opportunities of becoming acquainted with the practical methods of treating dynamos and electric light plant. Considerable additions are also being made to the electrical measuring instruments of the school, and it is proposed to utilise the town electrical supply for experiments with alternating currents, as well as for lighting a part of the building. The remainder of the school premises will be gradually wired by the students.

Electroplating Ships' Bottoms.—Invention has not, it is objected, yet reached the point of adequately protecting a ship's bottom from barnacles and seaweed. "Why not electroplate them with copper?" asks Mr. J. D. Darling, a gentleman well known in conjunction with the large aluminium electroplating contract at Philadelphia. "The first expense," he says, "of course, would be great; but the actual cost of plating a large ship after the first expense for solutions, dynamos, and a suitable dry dock would not be excessive. At first glance there are other objections that appear. The difficulty of keeping a large surface of iron clean until the first coat of copper could be deposited is one. This can be overcome by a plan I used to keep the surfaces of the iron columns for the Philadelphia public buildings clean. They had each a surface of about 300 square feet, but after being pickled and freed from rust and scale, there was no trouble in keeping the exposed iron surface clean and free from oxide until such time as they could be got into the plating-tank, and as they weighed about six tons, this took some time. Another objection is that copper deposited from a solution of sulphate of copper always contains pin-holes, which, of course, would admit the sea-water and set up galvanic action between the copper and the iron of the hull. Also, that the surface of the deposited copper would be rough, and thus interfere with the sailing qualities of the ship. These objections I have overcome by the use of a new plating solution that deposits copper in a much finer and more dense state than that deposited from the ordinary sulphate solution. Copper deposited from this new solution is entirely free from pinholes, and the surface, no matter how thick the coat, is perfectly smooth. It also adheres much better than ordinary plating, which is of great advantage, as there will be less danger of its being torn off by the accidental grounding of the ship in a sand-bar. In fact, there would be little danger of the copper being torn off anyway, as copper, when properly deposited on a clean iron surface, adheres very firmly, and nothing short of striking a rock or other equally hard obstruction, would injure it."

Lighthouse Flashlights.—In a paper dealing with this subject, read on Tuesday before the International Maritime Congress, M. A. Blondel referred to the apparatus called *feux-éclairs* for producing flashlights, designed by M. Bourdelles, and used by the Service Central des Phares de France. This new type of lens, he said, allowed of the realisation of a luminous power hitherto unknown without increasing the intensity of the source of light or the expense of construction. For

electric flash-lights it could not be thought of rigorously proportioning the diameter of the source of light to that of the lens, since that would lead to very considerable sizes for the carbons. The author gave a table, from which, although many of the figures had only hypothetical value, interesting conclusions could be drawn. For instance, for the fourth order (focal length of lens ·30 metre), the light with two panels would only permit of the complete utilisation of the arc light up to 100 amperes; for the higher orders four panels were more than sufficient, and the period of flash being much inferior to the maximum time, there was nothing to prevent a further increase of the intensity of the current, the quantity of additional light so produced being completely utilised. There was then at present no material impossibility in establishing electric flash-lights giving not merely 8,000,000 jets with 100 amperes, as indicated by the table referred to, but even 30 to 40 million c.p. with currents of 400 to 500 amperes, such as often spoken of in England. Such a light placed at a height of 1,000ft. would have a range of 186 miles. Having explained the physiological phenomena which accompanied the vision of instantaneous flashes, and having put forward a rational theory of these phenomena, the author established certain propositions, of which the following may be quoted: (1) Every source of light employed in a lens is capable of furnishing at each flash a quantity of light that only depends on its intensity, and the coefficient of vertical concentration of the apparatus, and on the interval between the flashes. This is fixed by considerations of a practical nature at the value of five seconds. (2) The electric flash-lights could realise the maximum utility at any distance. (3) The range that may be reached with electric flash-lights are now no longer limited by the luminous intensity, but by the height of the tower that would have to be constructed to render them available.

Luminous Power of Lighthouse Apparatus.—M. Bourdelles, Inspector-General des Ponts et Chaussées (France), read a paper on this subject on Tuesday before the International Maritime Congress. He said that the determination of the luminous power of lighthouse lights—that is to say, the useful effects they produced on the eye of the navigator at different distances—had led to numerous investigations in many countries. It had up to the present been agreed in France that the power was equivalent at any distance to that of a naked light of an intensity determined by photometric measurements. It had consequently been represented by a number of carcels decided from laboratory experiments. With regard to the luminous power as dependent upon weather, in more or less foggy weather, when the want of transparency reduced the luminous range to a distance such that the navigator perceived the intrinsic brightness of the apparatus, it was necessary to increase that brightness as far as possible. Under those circumstances, two lights of the same total brightness, but having different intrinsic brightness would be unequal in range and visibility, although they might be equal in ordinary weather. From that point of view, preference should be given to the arc lamp over the incandescent lamp, and to oil burners over gas; similarly to an electric lamp over an oil or gas lamp. For the same reason, with equal luminosity, the apparatus of small dimensions adopted in France for electric lights was superior to those of the second or third order preferred in other countries. It would seem to follow from recent experiments made in England and France that the intrinsic brightness produced by the voltaic arc in electric lighthouses remained constant whatever be the nature of the carbons, their diameter, or distance apart, or whatever be the *régime* of the current. If that was so, the illumination obtained by the apparatus ought itself to be invariable, and the luminous power of an apparatus of a given order would be independent of the electric burner that illuminated it. The dimensions as well as the intensity of the burner would only affect the divergence of the pencil, and it would be immaterial, as regards the luminous range, whether more or less electrical energy was expended. The author, however, observed that photometric measurements of the most unassailable character, made in great numbers in France, on the power of electric light, contradicted those conclusions. They proved, he said, with the utmost certainty that the illumination varied, as if the intrinsic brightness was itself variable and in conformity with the laws governing burners of other kinds.

A Call to Action.—England is within measurable distance of losing much of its prestige as a manufacturing nation unless it look to its affairs; and the reason of this is the advent of electricity. Switzerland, once apparently barred from heavy engineering enterprises by its lack of coal, now stands, by reason of the widespread use of water power, well in the forefront for engineering works of certain kinds. America owes much of the enormous engineering activity of the last few years to the effect of electricity in stirring into action powers of organisation for lighting, for traction, for transmission of power, that had but partially become awakened. The enormous mechanical energies of waterfalls have been seized upon. Niagara, on whose wasted forces envious eyes have long been cast, has at last been tackled, and ere long its power will be transmitted far and wide through the States. What is England doing, one may ask, in this new outbreak of mechanical activity—anything worthy of its heretofore supremacy? A few central stations here and there dotted over its surface; factories whose engine power, in reality, is outweighed by thousands of mills and workshops, of which no note is ever taken. The source of England's greatness has lain in its coal supply, and in the use thereof by its keen-witted practical men. When other countries are learning the lesson of the economical utilisation on a large scale of the water powers they are dowered with, England must readjust the commercial organisation for the use of its source of power—the coalfields. If capital can be secured to dig pits and tunnels for Niagara and other waterfalls, and to erect electrical machinery on enormous scale for the distribution of power; and can find capital to dig pits and tunnels for the raising of coal, it can surely find capital and means of utilising this coal power usefully at the colliery, in the same way that other countries use their water. Fuel under these circumstances would cost but little more than water; the works to utilise it would not necessarily be much more expensive. In the shifting of the balance of power in the world which is apparently going on now, this transportable property of electricity must not be left out of account. We are far too much behindhand in electrical transmission affairs in England. Can we not take the measure of our property, of our needs, of the possibilities of electric transmission, and produce after this hesitation something that shall be of worthy greatness in conception and in execution? The utilisation of the coal at the coalfields is evidently the practical problem of the immediate future, and the difficulties are more those of business organisation by capitalists than of mechanical or electrical disabilities.

High Temperatures.—We alluded last week to the curious experiments of MM. Hoho and Lagrange on the attainment of very high temperatures by using an electrode, as iron, dipping into an electrolyte, such as sulphuric acid.

M. Leroy, in *L'Electricien*, describes some later experiments. The apparatus used is a vessel of glass or porcelain, provided with a sheet-lead electrode, connected to the positive pole of a continuous current generator; the vessel contains sulphuric acid and water. A flexible cable from the negative pole is connected to a strong pair of pliers with insulated handles. Taking in the pliers a piece of metal of any kind, as iron, for instance, and immersing it in the acidulated water, the liquid is seen immediately in ebullition near the metal plate; the plate itself is rapidly heated, brought from red-hot to a dazzling white heat in a few seconds. If the experiment is continued, the heat becomes so intense that the iron begins to melt in spark-like drops; the surface remains constantly brilliant and clean, suitable for welding. The heating is produced so rapidly, locally, that neither the water nor the body of the iron plate have time to become hot, so that when the current is stopped the iron rod or plate—one end of which is incandescent—can be held in the hand. By using a rod of carbon instead of iron, fragments of amorphous carbon are seen dropping off in a few instants, indicating that the temperature has risen to 4,000deg. C. The rapidity of heating depends on the current and other conditions. In the experiments at Berlin the inventors used a current of 220 amperes at 120 volts, the calorific efficiency of the current under these conditions reached nearly 50 per cent. The inventors claim to have actually obtained, with larger currents, a temperature of 8,000deg. C. The explanation given is that the water decomposed electrically, is dissociated still more rapidly under the effect of heat. The oxygen is carried to the positive pole, the lead plate, and produces no effect but a slight oxidation over a considerable surface; the hydrogen, however, being given off round the negative electrode, surrounds it with a sheath of hydrogen gas, which, being a bad conductor, offers great local resistance and gives rise to great heating. The presence of this sheath also explains the clean surface of the metal, which enables it to be so easily welded. The advantages of this method of working metals electrically are apparent. There is another application which these experiments would seem to lead towards—the tempering of one edge or one extremity only of steel cutting tools; and again the hardening of the skin surface of large pieces of metal, such as armour-plates. It is stated that Krupp's are already trying this new method of electric heating for tempering the superficial surface of large guns. Chemical science may also be indebted to this new method of obtaining enormously high temperatures. New dissociations of elements may be brought about, and the artificial diamond, the philosopher's stone of the nineteenth century, may perhaps issue from this intense fire. It is pointed out that the experiments are not entirely novel, as M. Leblond, professor of electricity at the French Torpedo School, two years ago drew attention to the heating of wires in acidulated acid when the pressure is over 60 volts. These experiments were carried on with currents up to 120 volts pressure. This region of experiment seems to offer a fascinating field for further exploration.

An Electro-Cyanide Gold Process.—There are several electro-chemical processes for obtaining gold from refractory ores—that is, ores in which the gold is associated with sulphur, iron oxide, arsenic, antimony, or zinc, and similar deleterious substances. The presence of any of these ingredients acts prejudicially on the mercury used for amalgamation, rendering it sluggish and incapable of seizing upon and retaining the particles of gold. It is to neutralise this effect and to maintain the "quickness" of the mercury, no matter how deleterious the character of the ore, that such processes have been devised and put in practice. It is found, however, that some ores are amenable to one process and some to another, and that no one particular process is available for every class of ore. Hence it is said that expensive plant and machinery is sometimes put up for treating a given kind of ore, and the character of that ore becomes changed so that the process adopted becomes useless and another has to be superadded. To meet such cases and to discover a universal process which should be capable of dealing with every kind of refractory ore, says the *Times*, has long been the study of Mr. J. B. Hannay, F.I.C. He at length appears to have succeeded in his object in a simple and practical manner and by a cheap and expeditious electrolytic process. The main requirements are: (1) The circulation of the pulverised ore between positive and negative poles; (2) a solvent liquid for the gold; (3) means of collecting the electrolysed gold; and (4) the construction of the positive pole. The first requirement is met by having a screw propeller set vertically near the bottom of a tank, so that the powdered ore mixed with water to the consistency of a fluent sludge is agitated by the screw and driven downwards and outwards, up the sides of the tank, and back down the centre again. Rotatory motion of the mass of fluid is prevented by means of a baffle. The solvent is a dilute solution of potassium cyanide, and the collection of the gold is effected by a bath of mercury, which constitutes the negative pole. The positive pole consists of a mixture of powdered plumbago and powdered pitch or resin, these substances being consolidated by heat. This compound is found to set very hard and to form an excellent conductor, a ring of it being placed around the inside of the vat, which is circular. In operation the ore, mixed with a certain proportion of water, is placed in the vat with the bath of mercury at the bottom. On starting the screw, the mixture circulates down the centre of the vat and impinges gently upon the surface of the mercury. It then travels up the sides of the vat, which are conical, and on which the positive pole is laid, and back down to the centre, to be again driven into intimate contact with the mercury. The gold is thus brought into contact with an active instead of a sluggish mercury surface, over and over again, until every atom of gold has been seized and absorbed. The refractory particles of gold are dissolved by the cyanide and at once transferred to the mercury by the guiding power of the current. When the process is complete and all the gold extracted, the sludge is run through a rough filter and the cyanide solution returned to the tank to be used for operating on a fresh charge. The time occupied in treating a batch is put at from two to six hours, according to the character of the ore. It is stated that various kinds of refractory ores, including some typically difficult ones, have been submitted to treatment by this process, with the result that in some cases over 90 per cent. of the contained gold was extracted. The advantages claimed for the process are that the gold is extracted directly from the ore without roasting or any preliminary treatment other than crushing; that the same chemicals are used over and over again; that the process efficiently extracts the gold and silver from the auriferous ores whether refractory or free; that the precious metals are obtained at once from the amalgam in the metallic state, no precipitation or complex chemical methods being required; that any workable quantity may be treated in one vessel at one operation, and the gold obtained in one day. A demonstration of the process was recently given by the Universal Gold Extraction Syndicate, of 73, Basinghall-street, London, at which the apparatus was shown in operation.

ALTERNATE-CURRENT TRANSFORMER DESIGN.

BY R. W. WEEKES, WHIT.SCH., A.M.I.C.E.

(Continued from page 8.)

The three transformers worked out above by no means exhaust the types which have been used by the numerous manufacturers, but after carefully following the methods of design the reader should have no difficulty in working out details for any shape of core or of winding. Care must always be taken that in building up the core, no bolts, or other mechanical parts, form complete circuits embracing parts of the induction through the iron core. Otherwise secondary currents are induced, which add enormously to the losses.

The only remaining type which requires distinct treatment is the Hedgehog, an open-circuit transformer introduced by Messrs. Swinburne and Co. In this case the iron circuit is not closed, and the whole of the induction has to return from one end of the core to the other by the air. The advantage claimed for this transformer was that it had less iron loss than any ordinary closed circuit transformer. This has been proved to be a fallacy by Dr. Fleming's measurements on a three and a six kilowatt transformer, which had no-load losses as great as most closed-core types. He also showed that the manufacturers have been misled by a wattmeter which gave low power reading on inductive circuits. The grounds of the statement that there is less iron loss appears feasible at first sight. Suppose the transformer last designed was taken, Fig. 21, and the iron yokes were cut away just after the bend. This would reduce the weight of iron to one-half its former value. Then, if the same induction were used, the iron loss should be halved. But for the fact that the core is rectangular, we should now have a Hedgehog.

Figs. 22 and 23 shows the construction of this make of transformer. The core consists of thin iron wire stiffened by a gunmetal casting, which forms the support for all attachments. The iron wire is laid in between the flanges of this, and then bound tightly up with twine. Wooden flanges to support the copper wires are slipped on over the core. The winding of the coils is carried out much in the same way as described in other cases but for the fact that they are wound *in situ*, and that two sets of secondary winding are used, one each side of the primary. The ends of the wire core are spread out after the wooden flanges have been passed over them. The object of this spreading is to decrease the magnetic leakage along the core as much as possible.

The first abnormal point requiring notice is the large no-load current required. Thus, in the six-kilowatt tested by Dr. Fleming, the no-load current was 47·5 per cent. of the current required to furnish six kilowatts at the normal voltage of the primary. The actual loss at no load was 2·75 per cent., so that the current required to magnetise the iron, i_μ, is $\sqrt{47{\cdot}5^2 - 2{\cdot}75^2} = 46{\cdot}6$ per cent., and

$$\frac{i_\mu}{i_h} = \frac{46{\cdot}6}{2{\cdot}75} = 17.$$

Now, in the closed-circuit transformers designed above, this ratio was slightly greater than unity, and in many transformers with superior brands of iron it falls below unity. The high value of i_μ in the Hedgehog transformer is due to the air resistance in the return path of the magnetic lines.

Again, it will be noticed that the iron loss was 2·75 per cent. of the total output, whereas if the transformer, Fig. 21, had its iron reduced by cutting away the yokes, the loss would be only 1·25 per cent. This, of course, may be explained by assuming that in the Hedgehog transformer the iron is worked at a much higher induction, but it is likely to be due to causes peculiar to the type. The lines of force in this transformer are supposed to flow along the full length of the iron and then to return by the air, and the turning back of the wire core at the ends does much to ensure this. Still, lines of force do leak out before the ends are reached to a much greater degree than occurs in any closed circuit transformer. The result is that to maintain the same E.M.F. in the wires, the total flux in the central sections has to be increased to make up for the smaller flux cutting the end conductors. Although the mean induction may be the same, the higher density in the centre will increase the total iron loss more than the diminution of density at the ends reduces it. Then, too, the leakage lines have to pass through the copper, and in so doing may cause eddy currents to an appreciable amount. These causes are likely to account for the no-load loss being considerably higher than would be expected from the quantity of iron used.

Fig. 22.

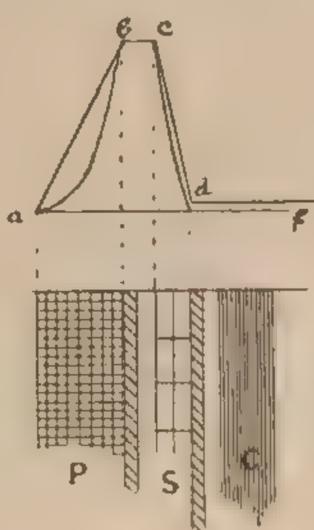

Fig. 24.

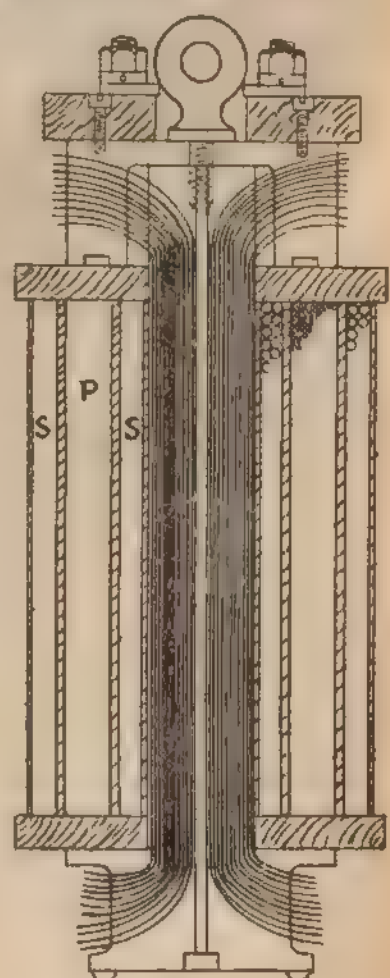

Fig. 23.

The large current at no load is the great disadvantage of this type, because although wattless in the transformer it causes losses in all the conductors. Also, it heats the alternator armatures as much as if the apparent power were being actually supplied. Thus, if a station were equipped solely with Hedgehogs, at least 40 per cent. of the plant would have to be run continuously. The method suggested of overcoming this disadvantage is that of using condensers in parallel with the transformers to supply this large current. The dielectric losses in the condensers then have to be considered, and they are far from negligible. Even if the open circuit have the advantage claimed of little or no load loss, it does not follow that it is better than a closed circuit; for if two such transformers are taken and placed side by side, the iron at the ends would need a very slight increase of length in order to complete the iron circuit through the two. The result is a closed-circuit transformer of twice the

output and about twice the iron loss. This loss will be reduced below the sum of the two individual transformer losses, owing to the uniformity of induction resulting from the completion of the iron circuit. The current at no load would of course be reduced to the normal amount required by a power factor of, say, 70 to 80 per cent.

Large transformers are expected to be more efficient than small ones, but still the combination thus made will show at once the advantage of having a closed core.

Magnetic Leakage of Transformers.—This branch of the subject is one that cannot be satisfactorily treated by calculation alone, and even when aided by previous experiments it is not easy to predict accurately the leakage effects in a new design. When a transformer is working a full load, the internal reactions cause fewer lines of force to pass through the secondary than through the primary, and hence we find a larger drop of volts than can be accounted for by loss in the copper. It is usual to deduct the known C R losses, and to call the remaining drop in pressure "magnetic leakage." When a transformer is working light the primary supplies the current necessary to magnetise the core and the secondary has no current in it, hence the action is simple and there is no differential magnetising effect. Now at full load in the third design the primary current has increased to 26·5 times its previous value, and we have the secondary current opposing the magnetising force of the primary. At no load, the magnetising force just inside the primary due to i_μ (·0864 ampere) would be $\frac{i_\mu \tau \, 1{\cdot}76}{l}$, where τ = the turns per coil, and l = the length of the coil.

$$\therefore H = \frac{{\cdot}0864 \times 865 \times 1{\cdot}76}{23{\cdot}5} = 5{\cdot}6 \text{ in C.G.S. measure.}$$

So that the induction in the air would be very small—*i.e.*, 5·6—compared to that in the iron. At full load the current rises to three amperes; so the magnetising force in the air space just inside the primary will now be

$$\frac{3 \times 865 \times 1{\cdot}76}{23{\cdot}5} = 195.$$

This will give an induction of 195 lines per centimetre, which, when multiplied by the area, gives a leakage flux which is appreciable.

The action is not confined to the actual space between the windings, but extends into the wire. Thus, in Fig. 24 the values of H are plotted over a section of the winding space. The magnetising force rises to its maximum value just inside the primary winding, and maintains this value till the secondary current causes it to fall. Halfway through the primary the force will be half the maximum, but as half the turns only are cut by the leakage lines generated here, the effect, if considered as acting on the whole number of turns in the primary, will be represented by half the ordinate at this point. Proceeding in this way, we get the total equivalent leakage effect, each point which is represented graphically by the curve lying under the lines, *a*, *b*, *c*, *d*. The area included between this curve and the abscissa, *a*, *f*, represents the total leakage flux when multiplied by the mean perimeter and constants depending on the scale to which the curve is drawn. This figure represents the number of C.G.S. lines which are acting on the primary only. It will be found that the flux thus obtained is a larger percentage of the total flux than the drop due to magnetic leakage is of the total voltage. This is because the leakage field thus summed up is in quadrature with the induction in the iron. Hence its effect must be worked out as acting at right angles to the flux in the iron. When this has been done, an approximate figure will be obtained generally underestimating the leakage, because no notice has been taken of the return path of these leakage lines. With careful consideration of all these points, it is possible to obtain a fair approximation to the leakage effect, but when working on one given type experiments give a more valuable guide. It is better in working out transformers to obtain the number of ampere-turns per given length of leakage path, and then by comparison with previous experiments to determine the probable leakage effects. When measuring the magnetic drop, great care must be taken that the circuit used for the load has neither induction nor capacity in it. Otherwise the results will be practically useless. Very little capacity will completely annul the drop, and, on the other hand, induction increases it.

In connection with leakage it must be clearly remembered that it is only alteration in magnetic flux due to the secondary current that causes bad regulation. Leakage of the induction in the core across to the yokes, such as is found in all magnetic circuits, has no harmful effect on the regulation. Thus the Hedgehog transformer virtually has the return path of the magnetic lines as leakage, and yet it regulates as well or better than many closed circuits. This is due to the fact that the differences between the magnetising force of the primary at no load to its value at full load is nearly 3 to 1 instead of 26 to 1, as in the transformer above. This leakage, which does not affect the regulation, may, however, be very harmful in causing eddy currents in both iron and copper, and a Hedgehog transformer made with a core of iron plates would show this at once by giving a larger iron loss than with the wire core.

(To be continued.)

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC.MEM.INST. ELECTRICAL ENGINEERS.

ARC LIGHTING.

(Continued from page 29.)

Fixing and Trimming.—The structural arrangement of a building has a great deal to do with the hanging of arc lamps, since the positions in which the lamps are placed are mostly regulated by the position of the girders, columns, etc., so that they must not be hung anyhow and anywhere. When determining these positions, provision must be made for getting at the lamps easily and quickly for repairs, trimming, cleaning, etc.; difficulty of access causes loss of time and loss of money, and, in addition, is often a perpetual source of annoyance to the occupiers of the place that is lighted. Buildings that are roofed by a lofty arch are particularly troublesome to deal with. Take the case of a railway station as an example, where the span is built of iron and glass. This must be wired without incurring the enormous expense of using scaffolding, and calls for a fair amount of activity and nerve on the part of those engaged in the work. The lamps should in these cases be fixed on either side of the centre of the arch, that is if the lighting arrangements allow of this being done. Another matter of importance, and one that will give plenty of scope for carrying out ingenious plans, is to wire the place in such a way that the length of cable used is brought down as low as possible. A vast amount of cable can be wasted on jobs of this sort, unless a good economical wiring scheme is thoroughly thought out. Great precautions must be taken that there is good insulation everywhere. When running cable along iron girders, etc., porcelain insulators must be freely used, so that at no point does the cable come in contact with the ironwork.

Arc lamps are best hung with steel ropes—No. 8 will do; and since it is a common thing for them to have the negative cable connected to the metal framework of the lamp, therefore the steel rope must pass through an insulator. In place of the iron hook at the top of the framework some lamps have a little porcelain pulley.

Every lamp is provided with a cut-out switch by means of which the lamp can be cut out of circuit. Should it be necessary to handle the lamp in any way when the current is on the circuit, it is of the most vital importance that the trimmer should switch that particular lamp out of circuit before attempting to touch it; it is only the work of a second, and personal safety is then ensured. Through neglect of this simple precaution several fatal accidents have taken place—all owing to gross carelessness on the part of the trimmer; because this is a most rigid rule in all arc light central stations, and need be so, when it is remembered that the working pressure is often 3,000 volts or so. An arc lamp can be hung, "fixed" or "movable." In the former case, the trimmer has to carry

trestles from lamp to lamp, which involves a good deal of labour and loss of time. This is speaking of indoor lamps For outdoor lamps, such as those for street-lighting, the trimmer only needs a light ladder, because the lamps are fixed on standards or projected from walls.

By going to a little more expense, indoor lamps can be made movable by using a lowering gear with a counter weight. In this case the lamp can be drawn down to the floor for trimming, etc, and then shot up again; the one objectionable feature of this method is the presence of the "slack cable." A 10-ampere cable, well insulated, is about as thick as one's thumb, and when banging loosely has an unsightly appearance; to avoid this, several devices have lately been brought out to automatically wind and unwind this slack as the lamp is moved up and down.

An arc lamp should never be suspended by means of its own cables. The weight of the lamp should in all cases be taken by a means of suspension perfectly independent of the cables, and when the lamp is at its proper position the cable should have no more tension in it than to give a fairly taut and trim appearance.

When lamps are hung from posts, out of doors, in exposed positions, it is necessary to fasten the bottom of the lamp to its support, otherwise it will sway about in a high wind.

Putting a fresh pair of carbons into a lamp, to replace those which have burnt away, is called "trimming," and the man who attends to this duty and looks after the lamps generally, is called a lamp trimmer. In trimming, great care must be taken that the two carbons are put in their holders so that they are perfectly in line. The carbon-holders are made adjustable in most lamps, so that they can be shifted about. When a carbon does not fall in line, it will often be found that simply turning the carbon round a little will make it right. When trimming a lamp, always put in the positive first, and then allow the lamp to run down slowly. If the carbon is fixed right, it will glide through the aperture of the negative carbon-holder, thus proving that this one is centrally fixed; it only remains now to fix the negative so that its point is opposite the point of the positive. The brass rods of the lamp should never be cleaned with emery-cloth, because the constant rubbing would produce wear and the adjustment of the lamp would be spoilt; only paste should be used; at times when the rods have become very dirty, a little crocus-paper might be used, but only sparingly. Lamps that are fixed in foundries, smelting works, and all such places of this sort, get smothered with grime and dust. The mechanism of such lamps should be well covered up. When lamps are fixed anywhere near to the sea, such as on the promenades of seaside places, if they are only used for the summer season, they should be taken down and stored away when the season is over. When in use they will require well looking after, because they are exposed to stormy weather, and the sea-brine in the atmosphere tends to rust the mechanism of the lamp. The cables should always be buried underground if possible, or, at least, protected as much as possible from the atmosphere, and, in particular, they should be placed where no sea-water or sea-spray can wet them.

Running in Parallel.—In an incandescent system of lighting it is very often required to run a few arc lamps. The lamps are then run two in series across the mains—any number of pairs of lamps can be run like this. When the pressure is above what is required for two lamps in series the surplus is absorbed by a small resistance coil placed in series with the lamps, so that the electrical power consumed by the pair is the product of the circuit pressure into the current the lamps take; of this power, evidently that absorbed by the resistance coil is wasted. For example, suppose we have a number of incandescent lamps working at a pressure of 110 volts—two "full" arc lamps take about 10 amperes—and a pressure of, say, 42 volts each, there is then $110 - 84 = 26$ volts left, and since the same current passes through both lamps and resistance coils, therefore $26 \div 10 = 2.6$ = the resistance, in ohms, that the resistance coil must have in order that 26 volts shall be absorbed in forcing a current of 10 amperes through it, because $10 \times 2.6 = 26$. The above figures relate to some arc lamps run off an incandescent plant now *at work*. Lamps that are run in parallel always burn better when there is a good margin of pressure, even though this extra pressure is absorbed by a resistance. To run a single lamp on an incandescent circuit would require a large resistance coil unless the circuit had a very low pressure, such as 70 volts, so that for the usual pressure of incandescent circuits, 100 or 110 volts, as much power would be wasted in the resistance coil as would run a second lamp.

In the event of one of the two lamps that are run off the mains going out, or otherwise failing to act, the second one goes out as well, there being no cut-out as a rule on lamps adapted for parallel running; the reason of this is that the remaining lamp would have double the pressure, and hence its current would be doubled, which would at least damage the regulating coils of the lamps, and in all probability burn them up.

(To be continued.)

MUNICIPAL ELECTRICITY WORKS.*

BY ROBERT HAMMOND, M.I.E.E.

Whoever essays to bring the subject of municipal electricity works before the municipal and county engineers of England must do so with some feeling of trepidation, for if proved that such works ought to be universally established, there will be thrust upon the shoulders of, perhaps, the hardest worked body of gentlemen in the United Kingdom a new and onerous responsibility. The writer, as an excuse for his temerity, presumes that in each case where the management of the municipal electricity works is committed to the care of the borough engineer, the ratepayers will, with their usual generosity, take care that this gentleman is enriched with a portion of the profits arising therefrom.

Before dealing with the question from a municipal point of view, a few minutes may profitably be devoted to the history of the establishment of the electricity supply industry in this country Up to the year 1879 very little electric lighting of any kind was done in the United Kingdom, but the introduction in that year of a new arc dynamo which was a sound engineering job, and which could run for long spells without breaking down caused quite an outburst of activity. The result was that almost all large works which were in operation by night as well as by day, adopted electric lighting. In some, the electricity was "generated" at a centre for distribution over a large area, and thus the idea of central stations became familiar Public lighting was started in the metropolis and elsewhere, but in the early eighties there was no "private lighting" to bear its share of the standing charges, and the public lighting contracts, being taken at a loss for the sake of advertisement, were, in almost every case, not renewed on their expiry. In three places in England, however—Brighton, Eastbourne, and Hastings—public-spirited and plucky individuals kept the central stations at work, and, adopting the rough means then available for running incandescent lamps on arc circuits, gave the customers the choice of arc or incandescent lighting, and, by the actual experience of years, exemplified the ease with which incandescent electric lighting over an extended area from one centre could be accomplished. At Brighton, from the beginning the supply was by means of overhead wires; but at Eastbourne and Hastings the distribution from the very first was effected by means of underground mains. The companies established in these places were followed by others formed by private enterprise at Liverpool, Sheffield, Bournemouth, and Bath, in the provinces, and at the Grosvenor Gallery and Kensington, in the metropolis.

On the passage of the Electric Lighting Act of 1882, 14 local authorities obtained provisional orders, but until 1889 not one of them was put into force. In that year the first municipal electricity works were opened at Bradford, and these proving successful, municipal electricity works are now in operation in nine places, embracing districts so widely different as St. Pancras, Dublin, Brighton (undertaken in order to prevent a local electricity company from getting a provisional order), Hull, Nelson, and Glasgow.

To give a clear idea of the present position of electricity supply in the United Kingdom, there follows a tabulated statement of the works holding statutory powers at present in operation, the capital invested being set out and a discrimination made between those works situated where the gasworks belong to the corporation and where they belong to a company. This (Table A) is not confined to works belonging to local authorities, because the amount of capital already invested in the industry by private enterprise, as indicating the opinion

* Paper read before the Incorporated Association of Municipal and County Engineers at the annual meeting at West Bromwich, July 13, 14, 15, 1893.

of capitalists, has a very important bearing on the question of the soundness of the electricity supply industry

TABLE A.—ELECTRICITY WORKS (HOLDING STATUTORY POWERS) IN ACTUAL OPERATION IN THE UNITED KINGDOM.—Statement of Capital Invested on June 30, 1893 ‡

	Totals	£3,967,654	£126,000	£264,200	£209,800

* These figures include debentures or loans. † December 31, 1892. ‡ There is excluded from this and the remaining tables the various works, mostly on a small scale, scattered throughout the country which are not working under statutory powers.

The works are arranged in the order of their date of starting the supply. The pioneer works are those at Eastbourne. The works owned by the private company at Brighton, established in 1881, would head the list, but they are excluded because the company there is working by means of overhead wires, without statutory powers. It will be seen that the total capital invested at the present time in statutory electricity works actually in operation is £4,557,654, which is contributed as follows:

SUMMARY OF TABLE A. *Electricity Works (with Statutory Powers) in Actual Operation.*

Owned by	Capital invested.
Companies	£4,083,654
Local authorities	474,000
Total	£4,557,654

In only two cases, where the gasworks belong to the Corporation—*i.e.*, Birmingham and Leeds—have the local authorities allowed a provisional order to go into the hands of a company. It is a matter of importance in these cases to consider the terms of purchase which are embodied in the provisional order sanctioned by the local authority. The Leeds terms are as follows: The Leeds Corporation has the right of taking over the works and business of the company

(*a*) At any time prior to July, 1901, by the issue to the company of such an amount of Leeds Corporation stock as will produce by the interest or dividends thereon an annuity of 5 per cent. per annum upon the sum expended by the company upon their undertaking and chargeable to capital account, and also the payment to the company of a sum equal to the aggregate amount of a dividend of 5 per cent. per annum on the said capital expenditure, less the aggregate amount of the dividends declared by the company up to the date of purchase.

(*b*) At any time from July, 1901, to July, 1912, by the issue to the company of such an amount of Leeds Corporation stock as will produce by the interest or dividends thereon an annuity of 5 per cent. per annum upon the capital account of the company. N.B.—For instance, if at the date of such purchase the capital so expended were £50,000, the company would receive sufficient Corporation stock to produce £2,500 per annum, the market value of which is now about £80,000.

(*c*) At any time between July, 1912, and July, 1922, either on the above named terms (*b*) or upon the Corporation paying the company the then value of the undertaking in accordance with Section 2 of the Electric Lighting Act, 1888, together with such additional sum as may be determined by arbitration to be the value of the goodwill of the undertaking.

(*d*) After the expiration of July, 1922, or at the end of every subsequent period of seven years, either on the terms of (*b*) or upon the Corporation paying the company the then value of the undertaking in accordance with Section 2 of the Electric Lighting Act, 1888; but the option of purchase on the terms of (*b*) ceases in 1933.

In addition to the electricity works already in operation, there are 25 new works for which contracts have been given out, and these are tabulated in the same form as the above:

	£25,000	Nil.	£444,972	£363,000

It will be seen that in the case of these new works none are being erected by companies in localities where the gasworks belong to the corporation, and that the amount of new work which companies have in hand bears only an insignificant proportion —10 35 per cent.—to that of local authorities.

SUMMARY OF TABLE B.—*Electricity Works in Course of Construction.*

Owned by	Capital invested.
Companies	£79,406
Local authorities	766,494
Total	£845,900

which sums, added to those given above (Table A), result as follows:

TABLES A AND B (COMBINED).—*Electricity Works in Operation and in Course of Construction.*

Owned by	Capital invested.
Companies	£4,163,060
Local authorities	1,240,494
Total	£5,403,554

But even this figure does not exhaust the budget, for there are 22 places in the United Kingdom in which statutory powers have been obtained and electricity works decided upon, but where the contracts have not yet been given out (Table C).

Again, note the great disparity in value of the new works 3·1 per cent.—decided upon by companies and by local authorities.

SUMMARY OF TABLE C.—*New Electricity Works Decided Upon.*

Owned by	Capital invested.
Companies	£25,000
Local authorities	807,972
Total	£832,972

Leaving the grand totals of

TABLES A, B, AND C (COMBINED).—*Electricity Works (with Statutory Powers) in Operation, in Course of Construction, and Decided Upon.*

Owned by	Capital invested.
Companies	£4,188,060
Local authorities	2,048,466
Total	£6,236,526

After this batch of figures, perhaps, no more should be inflicted, though to epitomise the exact position at the moment one should add a list of places where electricity supply is under discussion, but where no decision has yet been come to (Table D).

The above figures are significant. They indicate (1) that there is a consensus of opinion in favour of the establishment of electricity supply works; (2) that though the bulk of the pioneer work has been done by private enterprise, the newer works are almost all being undertaken by local authorities; (3) that with only two exceptions has any local authority owning the gasworks sanctioned the granting of statutory powers to a company.

Let us now consider whether the attitude of so many local authorities can be justified upon sound municipal and commercial grounds.

I.—MUNICIPAL POINT OF VIEW.

It would be out of place if, in connection with the subject of electricity supply, we embarked in a discussion as to the advisability of municipal trading. That has been thoroughly thrashed out in connection with water and gas supply; and it is now universally acknowledged that local authorities can with propriety become the distributors of these two commodities.

Pure water is the prime necessary of human life, and, though this cannot be said of gas, with regard to both it may be urged that (*a*) they are practically in demand by the whole body of ratepayers; (*b*) they are supplied, in any particular locality, to all consumers alike, whether rich or poor, in one uniform quality.

Let us apply these tests to electricity supply. (*a*) *The demand* may certainly be regarded as *universal*, the only limit to it being the question of price. (*b*) The supply to every ratepayer, as in the case of water and gas, is bound to be uniform in quality.

Price will be dealt with under the next head, and setting this aside for the moment, it would appear that, from the municipal point of view, electricity supply is on exactly the same basis as water and gas supply. But in the case of both the latter the undertakings have, almost universally, been started by private enterprise, and subsequently acquired by local authorities when they were assured successes. Is there anything connected with *electricity supply* that should make such a course inadvisable?

Let us first consider to what extent, if any, the ratepayers are prejudiced by the operations of a company. If a local authority sanction a provisional order on behalf of a company, the first step of the company is to select a compulsory area, limited in extent, but comprising the choicest portion of the town from the electric lighting point of view. Ratepayers inside this area are able, by the use of the electric light, to make their places of business more attractive, to the detriment, probably, of the ratepayers outside, who cannot demand a supply for two years, and can then only obtain it under onerous conditions of guarantee, etc.

How does this arrangement appeal to the town authorities, who are the guardians of the interests of the whole of the ratepayers and not of a select few? Presuming that a fair case can be made out for electricity supply from the commercial point of view, it should surely be the aim of a local authority to establish works in connection with which a supply is placed at the disposal of the whole of the ratepayers. No company, however, would accept so onerous a condition as making the whole city or borough the compulsory area; whereas, in the case of the local authority being the undertaker under the Electric Lighting Acts, the whole city or borough practically becomes the compulsory area.

It may, however, be urged that if a profitable demand present itself outside a company's compulsory area the company will, as a mere matter of business, extend its mains and enlarge its works. But in the hands of a company the growth of the undertaking must necessarily be slow. The shareholders, believing in quick returns, insist upon immediate and good dividends as the precursor to an enlargement of the capital account.

The business is, therefore, often cramped for capital from the beginning, and the unfortunate ratepayers in the "outside area" are left in the lurch. A municipality can afford to take wider views. If the business be in itself sound, its aim is to develop it on an extended basis as rapidly as possible. A local authority can afford to make "capital extensions" without waiting for a 5 or 6 per cent. return upon the work in the compulsory area; its principal aim being, with due regard to permanent profitable results, to extend the benefit of electricity supply throughout the whole of the district under its control. Again, it is obvious that the quickest way of developing the business is to offer the supply at a cheap rate. Bradford, for instance, is charging 5d per unit, equivalent to 2s. 6d. to 3s. per thousand feet of gas; St. Pancras, 6d. for light and 3d. for motor supply; Burton-on-Trent, 6d., etc. No companies, except those at Newcastle-upon-Tyne, have ventured upon starting with such low rates of charge as this. Far-seeing directors may be fully alive to the fact that such a bold policy is the best; but they fear the criticism of the timid shareholder, who might object to lean profits in the early stages of the business.

To bring my remarks under this head to a close, I will only refer to one other municipal consideration. It is often said that in the early period of the establishment of municipal electricity works the demand will not be universal, and the works possibly conducted at a loss, and that it is unfair that the whole of the ratepayers should incur a responsibility for the benefit of a comparatively limited number. It must, however, be remembered that the introduction of electricity supply to any town raises the status of that town, and indirectly results in a benefit to the whole of the ratepayers. Large sums are constantly being voted, with scarcely a murmur for the improvement of sanitary conditions; and the day will probably arrive, when before this very association, a paper will be read on the iniquity of the nineteenth century in permitting the distribution, by constantly leaking pipes, under the public streets, of such a frightfully noxious thing as coal-gas, and in encouraging the illumination of interiors with that which only gives out light by robbing the air of its life-giving quality—oxygen—and by returning to the air poisonous carbonic acid, to the marked lowering of the standard of health.

Ten years ago the writer, in his "Electric Light in Our Homes,"* pleaded, before the establishment of a single electricity supply works under statutory powers in this country, for the universal use of the electric light for interiors, and the arguments set forth then, now regarded as platitudes, are as strong as ever. The perfect light must fulfil the following conditions:

(1) Not feed on the air; (2) add no noxious fumes to the air; (3) give off no appreciable heat; (4) be free from danger of causing fire; (5) not injure a tradesman's stock; (6) do no damage to ceilings, furniture, etc.; (7) not injure the sight; (8) be quite reliable; (9) not escape; (10) be absolutely free from danger to life or limb; (11) be convenient, capable of being measured and economised, and arranged artistically.

It is in the hands of our municipal authorities to beautify their towns by the introduction of such a perfect light, and to place it within the reach of every ratepayer.

We will now turn to the consideration of the

II.—Commercial Point of View.

Until quite recently "electrical finance" has been under a cloud in consequence of the fruitless outburst of speculation which characterised the pioneer days of the industry. It cannot too often be repeated, however, that the money lost in 1883-84 was not lost in "electricity supply." Indeed, it may be stated that not one single concern holding statutory powers which has fairly embarked on its course, has come to grief. The large sum of four millions invested by the present supply companies in electricity works indicates pretty clearly the opinion of the commercial world as to the soundness of the industry. The following table shows the margins, on the right side, between costs of working and revenue as exemplified by the 1892 balance-sheets of 15 electricity works:

Name of works.	Margin between total costs and revenue.	On a capital of	Per cent. of margin to capital.
Birmingham	£3,488	£70,000	4·98
Bradford	1,476	34,243	4·31
Charing Cross	10,247	200,900	5·10
Chelsea	4,319	80,585	5·36
Eastbourne	1,746	37,119	4·70
House-to-House	2,830	76,795	3·69
Kensington	10,327	154,400	6·68
Liverpool	15,993	186,409	8·58
Metropolitan	18,168	549,741	3·30
Newcastle and district	2,140	33,240	6·43
Newcastle-on-Tyne	2,300	40,699	5·65
St. James	18,329	200,000	9·11
St. Pancras	2,576	91,269	2·82
Westminster	14,508	370,000	3·92
Brighton	2,229	52,563	4·24

* London. Fredk. Warne and Co., 1883.

It will be noticed that in almost all the above cases there is sufficient margin between the costs of production and the revenue to provide for the annual sinking fund required to repay the electric light loan, if the supply were in the hands of the local authority. The General Purposes Committee of the Birmingham Town Council have, however, just reported "that at present at all events the profits made from the supply of electricity are inconsiderable"; but they overlook the highly important fact that the bulk of the works in operation are only in the initial stage, and as they develop and the demand increases they will work at much cheaper costs and show much more substantial margins between costs and revenue. The increase in the demand, however, will largely depend upon the possibility of being able to directly compete with gas in price, for though we cheerfully pay more for newly-laid eggs than for "shop un's," the greater number of householders, as a rule, are compelled by stern financial necessity to give the preference to the less desirable article on account of its cheaper price. These will for like reasons continue to use the filthy poisonous gas until electric light comes within the range of their limited purses. What chance is there of such a happy consummation? By a wise provision of the Board of Trade, each "undertaker," under the Electric Lighting Acts, is compelled annually to file its complete accounts, and to set forth in detail its cost of production. These costs are regularly analysed in *Lighting*, a periodical which may be known to you, and that analysis need not be repeated here; but it may be noticed that, excluding the metropolis, where the conditions of production and supply are in many cases abnormal, there are works whose total costs of production are as low as Bradford, 4·04d.; Liverpool, 4·25d.; Newcastle, 3·48d. and 3·43d. per Board of Trade unit, so competing with gas at 2s. to 2s. 6d. per thousand feet. These costs cannot, however, fairly be compared with those of gas, because they are on the basis, as compared with gas, of a very limited production. It is fair to assume that when electrical energy is produced on the same scale as gas it will directly compete with it in price. One important feature in this connection is the series of improvements which are certain to occur in the incandescent lamps, on a par with those that have from time to time taken place in gas burners. When the incandescent lamp was first invented it required 5 watts to 6 watts for one candle of light. Now it requires, according to the size of lamp, 3 watts to 4½ watts for one candle of light. When the manufacture of incandescent lamps in this country is thrown open, and by various improvements in the filament less electrical energy is required to produce each candle of light, the comparison between electrical energy and gas as illuminants will become more and more favourable to electricity. If for the same amount of light a consumer should only use 100 units at 6d. per unit where he now uses 200, electricity to him will practically only cost half its present price.

Again, in the production of electricity at present there are no by-products, but there is a large margin for the utilisation of the electrical plant for purposes other than lighting. The work of generating electricity for lighting is only equivalent to about two and a half hours' use of the plant daily all the year round. If a full use for the plant during the remainder 21½ hours of the 24 were discovered, it would be possible to make a profit out of selling electricity at even less than 2d. per unit. This would correspond, say, to less than 1s. per 1,000ft. for gas. The advantages which gas derives from by-products will probably accrue to electricity in time through by-uses of the plant. However small, therefore, be the margin of profit at the beginning, there is a probability of large profits being made by degrees, without adding to or altering the plant.

To sum up, it may be contended that electricity supply is based at the present stage on sound commercial lines, and that its future is all in the direction of cheaper costs. The question, then, for a local authority to decide is whether it should keep the business in its own hands or sanction its being conducted by a company. If the latter course be adopted, the Electric Lighting Acts provide for a 42 years' tenure by the company. If an arrangement be made for an earlier purchase, it is manifest that the local authority will be called upon to pay a pretty heavy bonus. This, in the case of Leeds, it has been seen, was fixed at about 66 per cent., and in the more recent case of Reading it has been fixed at 33 per cent. It is, however, in any case manifest that the consumers are better off if supplied by the local authority than by a company, because the price charged by a company must cover the cost of administration by directors and also a provision of a good dividend to shareholders, whereas in the case of supply by a local authority there are no directors to pay and no fat dividends to provide. The local authority will easily be able to borrow the capital necessary at 3 per cent. to 3½ per cent., a rate that would hardly satisfy the shareholders in a company. The time at disposal does not permit one to go further into details, but the majority present will, it is hoped, be inclined to admit that a strong case both from the municipal and commercial point of view has been made out for the general establishment of municipal electricity works.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

TRACTION v. TALK.

Last week we commented in these pages upon the position of the National Telephone Company, drawing attention incidentally to the very considerable effect which would doubtless be felt in the telephone industry as a consequence of the then forthcoming report from the Joint Parliamentary Committee on Electric Powers (Protective Clauses). Since then the report itself has appeared, printed in plain black ink on plain white foolscap paper, published at the modest price of one penny, and weighing "under one ounce." There were no fireworks at Westminster when it was first issued; nor, *per contra*, could one hear the doleful strains of a Dead March in "Saul" within the purlieus of Oxford-court. And yet this business-like document will have an effect upon the electrical and allied trades generally throughout this country, to which no amount of engrossed or illuminated parchment addresses in gold and jewelled caskets could ever aspire.

In the first place, it opens up the way at once to more rapid and more reasonable developments in traction methods along our streets and roads than has hitherto been possible; and in the second, it practically compels the telephone service, wherever disturbances arise from an electric tramway, to rearrange its systems within two years on a plan which is confessedly the only one that gives complete satisfaction, which ought to have been adopted at the outset, and which is even now at certain points in process of reluctant installation at the instance of outraged and long-suffering subscribers.

"The undertakers shall, in the use of electric power under the provisions of this Act (order), employ either insulated returns or uninsulated metallic returns of low resistance." With a proviso as to lines where accumulator traction is employed, thus runs Section 1 of the model clause which the joint committee has drawn up. This is the essence of the whole matter, and one may well imagine those interested in the development of electric lines—when reading the apparently stern command "you shall employ," etc., etc.—feeling very much like the youths at a certain school where some amount of pardonable surprise was evoked by a notice to the effect that "Any boy found *outside* Mr. So-and-So's orchard will be severely punished." For electric traction purposes no further powers than those given by the clause would be necessary or desirable; uninsulated metallic returns of low resistance are practically in use to-day upon the majority of successful electric lines, and the result of the committee's investigation is therefore to confirm the employment of such, particularly in the case of overhead conductor systems. It is obviously to the best interests of an electric line that any metallic return should be of low resistance, but by emphasising this point the committee has done well, since it thereby ensures not only that the work of bonding a road for the return circuit shall be properly carried out in the first instance, but also that it shall be carefully maintained afterwards in good condition. Let it be said incidentally that the expression thus used—"bonding a road"—refers wholly and solely to the metallic return circuit: as

a rule, an electric tramway is more likely to prove a success when the bonding is not of a financial character.

Throughout the report there is a marked absence of special stress upon telephonic disturbances due to the use of electric power on tramways, although the enquiry which led to the appointment of this committee arose in no small degree from the readiness of the telephone company to have the matter settled once for all. It would therefore be a little discourteous to enlarge upon the snub direct thus given to the telephone interests; but one cannot help regretting the Tramway Orders or Acts already obtained on conditions wholly unfavourable to the use of the best electrical systems, and the only pity to be felt with regard to the model clause now settled is that it cannot be made retrospective.

Tacked on to the six sections of the clause are some resolutions or recommendations — ten in number—which have been adopted unanimously by the committee; these do not call for special discussion, except that the last one is not so clear as might be wished. We can hardly believe that the committee intended all developments in electric traction to be absolutely postponed for two years from now, and that all future enterprises will require at least that space of time to ripen wherever telephonic disturbance is likely to ensue, although the expressions used are capable of bearing that interpretation. Doubtless the meaning is that after two years have elapsed from the passing of a Tramway Act or order, the telephone company will have no *locus standi* whatever against those using electric power on the tramway with a consequent telephonic disturbance. For working the lines meantime an amicable arrangement between conflicting interests must apparently be entered into.

The whole case of "traction *v.* talk" may be summed up in the epigrammatic language of the "bard of Teddington"—viz., our streets and roads are for travel—not for talk; and this view has been upheld by the committee. The electrical interests may feel devoutly grateful that the matter is thus settled; even the telephone company—if only it knew what was best for itself—would appreciate the result. Would it not, however, be more than curious if in time to come the tramway companies should be found to occupy the position lately held by the telephone interests, on the score of interference with their circuits? Yet he would prove a rash man who could positively assert that no future electrical system might arise to disturb electric lines employing uninsulated metallic returns even of low resistance.

It is, perhaps, invidious to mention any names in chronicling a step forward of such a nature as this report. The advantages which it will develop are due to the hearty goodwill and energetic labours of many, but in common justice we put upon record, as having proved a mainstay of the agitation to get this matter settled with justice, the late Electric Traction Association and its secretary (Mr. Stephen Sellon). So long as the traction interests are looked after with a similar amount of care and foresight, we shall have no fear as to their speedy progress and prosperity.

MUNICIPAL ELECTRICITY WORKS.

This is the title of a paper read by Mr. R. Hammond before the annual meeting of the Municipal Engineers last week. The paper is given elsewhere, and is, as will be seen, mainly historical and statistical. Mr. Hammond is doing good work in pressing electrical matters to the notice of municipalities, but he would do better to leave out of consideration personal questions, such as the bracketed phrase relating to Brighton. It is a tactical blunder, especially in such a paper as this, read ostensibly to induce local authorities to take up the question themselves in face of all comers. Mr. Hammond would have added to the value of his paper if he had tabulated the losses from company work. From October, 1878, to December, 1882, fifty-six companies were floated, with a capital of £20,910,500. Assume that in the following ten years a similar amount of capital had been asked for by companies, giving a total, say, of £40,000,000. How much of this capital was subscribed, and how much is lost, and who has lost it? To tell the truth on these questions might be startling, if not libellous. If we are generous at the expense of truth, we may say that the loss was the cost by which private companies proved the success of the new illuminant. On the other hand, if we are truthful, we shall say that the majority of all the companies floated have been floated to put money into the pockets of promoters, and with very little idea of their being commercially successful. Fortunately, a few have been promoted on true business principles, and with a view to commercial success rather than to promotion-money. However we look at supply by companies, we must acknowledge that in the aggregate too much money leaks from useful works into financiers' pockets. It is not so with municipalities. They may be extravagant; their work may be wastefully done, but the financier is out of it. Hence, if from no other point of view, the "man in the street," who is unbiassed towards companies or municipalities, would at once vote for municipal action, because then the money obtained would at any rate be used in productive work. Ordinarily, the real cost of a central station to a company will be from 25 to 50 per cent. dearer than the cost to a municipality; and further, the latter can get its money from 20 to 40 per cent. cheaper. We are glad, therefore, to find from the statistics of Mr. Hammond that supply companies are dwindling and municipal authorities are increasing.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ACCUMULATOR TRACTION.

SIR,—I am very desirous of obtaining such information from Mr. Brockmam as will leave no doubt in my mind as to the superiority of accumulators over any other form of traction, and as Mr. Broekman has been good enough to

say he will be pleased to submit to me any such information, I should be glad if he would first state specifically what he meant when he said in his letter to you of the 28th ult. that "*The service of the line on which our accumulators are in use is to our knowledge more regular and reliable than that of any line operated on the overhead wire or conduit system,*" and from what source he has obtained this information.

Secondly, will he kindly prove by figures—which I presume he must have in his possession, when he also makes the statement—that "*It can be proved that such a line* (*i.e.*, a line worked by accumulators) *can be more economically worked than any direct-current system?*" On his supplying me with any figures of absolute working as to the total expenses per car mile for motive power, I shall then be pleased to supply him with practical figures of the present cost of working on the overhead system. Will he also give me the price per car mile at which he is prepared to guarantee for a term of years the working of the Bristol-road section of the Birmingham Central Tramways? I mentioned in my letter of the 4th inst. that I looked forward with much interest to the publication of the Birmingham Central Tramways Company's balance-sheet, to see how it bears out the alleged economy of the accumulator system, which means, in plain English: what are the expenses at the generating station, and what is the cost (over 1½d. per car mile which the Epstein Accumulator Company are at present charging for the repairs of their accumulators) of motive power per car mile?

Mr. Brookman states that this will be no criterion, because they have no power to interfere with this expenditure. If this is the case, will Mr. Brookman be good enough to furnish for my information what is the cost at present for this work (which he can obtain by the company's balance-sheet), and in what way and how much he can reduce this amount?

I am perfectly willing to accede to the Epstein Accumulator Company all that they are fairly and honestly entitled to claim, but as a practical man I require a little more information than they have at present provided before I am convinced.—Yours, etc.,
STEPHEN SELLON.

London, S.W., July 17.

INFLUENCE OF CURRENTS ON VOLTMETERS.

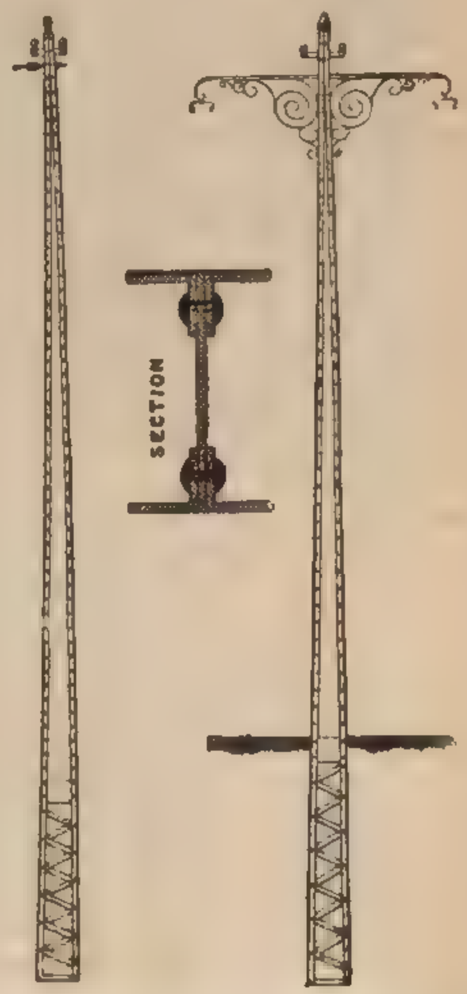
Voltmeters may measure accurately enough when free from stray influences, but if, like some instruments, there are errors of 20 to 50 per cent. near a conductor carrying a current, their value as accurate measuring instruments is lost. We have not seen any special tests given by makers of this nature until recently, when Messrs. Paterson and Cooper, in sending us their new catalogue of measuring instruments, also send the following statement of tests. These tests were made on their dead-beat electromagnet voltmeter to ascertain the error due to large currents in its proximity. They give diagrams showing the position of the instrument relative to the main carrying a very large current, and the error due to this influence at various distances.

Position.	Distance between instrument and main.	Current in main, in amperes.	Error in voltmeter.
Voltmeter placed upon main, main vertical.	Touching.	1,700	6 per cent.
	Raised 2in.	,,	[illegible] ,,
	,, 8in.	,,	[illegible] ,,
	,, 12in.	,,	0 ,,
Ditto, main horizontal.	Touching.	1,700	2 ,,
	Raised 2in.	,,	1½ ,,
	,, 5in.	,,	0 ,,
Voltmeter alongside main, main vertical.	Touching.	1,700	½ ,,
Ditto, main horizontal.	Touching.	1,700	¾ ,,
	1½in. away.	,,	½ ,,

From the above it will be seen that these instruments are practically unaffected by currents in their neighbourhood, unless placed directly over the leads, as in the first and second position.

TROLLEY WIRE POLES.

The decision of the Joint Parliamentary Committee on the traction *v.* telephone dispute is considered by all those who are qualified to speak upon the subject from an intimate knowledge of its full bearing to imply a rapid and immediate advance in the development of electric lines operated on the overhead conductor system, and until a better or cheaper method of working tramways can be devised, it seems useless for obstacles to be set up against the general adoption of this system simply on the score of its æsthetic disadvantages.



On suburban roads where tramcars perhaps already run, there can be no serious grounds whatever for opposing the introduction of an electric system, even on the overhead conductor principle, and but a very few years will pass before we shall see in almost every populous district in this country much greater facilities for cheap and rapid transit owing to the adoption of electricity as the motive power.

In view, therefore, of the undoubted early developments in this art, there will be many firms whose interests are directly affected thereby in a most beneficial degree. Amongst such we may classify those engaged in the manufacture or supply of iron and steel appliances required for

working an overhead conductor electric tramway. At present there seem to be very few indeed who have endeavoured to lay themselves out for this and similar work, with the idea of making it a speciality. The firms engaged in the manufacture of electric railway equipment—apart from strictly electrical appliances—are as yet quite in the background.

So far as the metal poles for trolley wires are concerned, these can be obtained even now from a few of the leading firms—such as the Messrs. Russells, Mr Joseph Aird, Messrs. Dick, Kerr, and Co., Messrs. J. Menzies and Co., and others; but there must be plenty of makers who might find sources of profit in a speciality, and in order to introduce such to their notice, as well as show what is being done elsewhere, a brief description is annexed, with illustrative engravings representing a steel trolley wire pole or standard which is put on the American market by the Berlin Iron Bridge Company, of East Berlin, Connecticut

It will be seen from the illustrations that this arrangement of standard is built up of a steel plate narrowed down throughout its length, and riveted on the edges to four angle irons, two on each side. The double ribs thus formed will undoubtedly give considerable strength where it is most needed—i.e., in opposition to the side pull—indeed, the makers claim especially for this type of standard that the strains can be determined beforehand very exactly, and the proper proportion of metal thereby employed.

An allowance of 6ft. in length is made for insertion in the ground, the base being opened out, as shown, into a lattice-work arrangement, so as to ensure a thorough bedding into the cement or concrete foundation.

Together with this pole the makers also supply a special type of span-wire insulator holder. This consists of a long screwed rod, with lock nuts for adjusting the strain, and a neat form of hood or covering, which is claimed to act perfectly as a protection against the formation of sleet or frozen snow on the insulator, whereby leakage might possibly ensue.

Without going so far as to admit any great superiority in these devices over such, for instance, as are employed on the South Staffordshire line, one cannot remember too often that even the best things are not perfect, and that much may be learnt from studying very carefully all possible types of appliances, quite irrespective of the commercial value which they may have in the English market.

ON LIGHT AND OTHER HIGH-FREQUENCY PHENOMENA.*

BY NIKOLA TESLA.

(Continued from page 19).

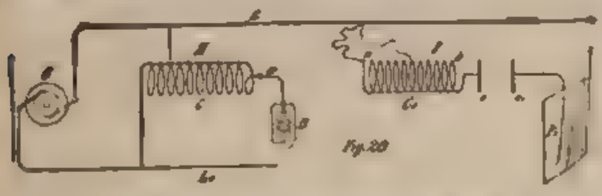
ON ELECTRICAL RESONANCE.

The effects of resonance are being more and more noted by engineers and are becoming of great importance in the practical operation of apparatus of all kinds with alternating currents. A few general remarks may therefore be made concerning these effects. It is clear that if we succeed in employing the effects of resonance practically in the operation of electric devices the return wire will, as a matter of course, become unnecessary, for the electric vibration may be conveyed with one wire just as well, and sometimes even better, than with two. The question first to answer is, then, whether pure resonance effects are producible. Theory and experiment both show that such is impossible in Nature, for as the oscillation becomes more and more vigorous the losses in the vibrating bodies and environing media rapidly increase and necessarily check the vibration which otherwise would go on increasing for ever. It is a fortunate circumstance that pure resonance is not producible, for if it were there is no telling what dangers might not lay in wait for the innocent experimenter. But to a certain degree resonance is producible, the magnitude of the effects being limited by the imperfect conductivity and imperfect elasticity of the media or, generally stated, by frictional losses. The smaller these losses, the more striking are the effects. The same is the case in mechanical vibration. A stout steel bar may be set in vibration by drops of water falling upon it at proper intervals; and with glass, which is more perfectly elastic, the resonance effect is still more remarkable, for a goblet may be burst by singing into it a note of the proper pitch. The electrical resonance is the more perfectly attained, the smaller the resistance or the impedance of the conducting path and the more perfect the dielectric. In a Leyden jar discharging through a short stranded cable of thin wires these requirements are probably best fulfilled, and the resonance effects are therefore very prominent. Such is not the case with dynamo machines, transformers and their circuits, or with commercial apparatus in general in which the presence of iron cores complicates or renders impossible the action. In regard to Leyden jars with which resonance effects are frequently demonstrated, I would say that the effects observed are often attributed but are seldom due to true resonance, for an error is quite easily made in this respect. This may be undoubtedly demonstrated by the following experiment. Take, for instance, two large insulated metallic plates or spheres which I shall designate A and B, place them at a certain small distance apart and charge them from a frictional or influence machine to a potential so high that just a slight increase of the difference of potential between them will cause the small air or insulating space to break down. This is easily reached by making a few preliminary trials. If now another plate fastened on an insulating handle and connected by a wire to one of the terminals of a high tension secondary of an induction coil, which is maintained in action by an alternator (preferably high frequency)—is approached to one of the charged bodies, A or B, so as to be nearer to either one of them, the discharge will invariably occur between them; at least, it will if the potential of the coil in connection with the plate is sufficiently high. But the explanation of this will soon be found in the fact that the approached plate acts inductively upon the bodies A and B, and causes a spark to pass between them. When this spark occurs, the charges which were previously imparted to these bodies from the influence machine must needs be lost, since the bodies are brought in electrical connection through the arc formed. Now this arc is formed whether there be resonance or not. But even if the spark would not be produced, still there is an alternating E.M.F. set up between the bodies when the plate is brought near one of them; therefore the approach of the plate, if it does not always actually, will, at any rate, tend to break down the air space by inductive action. Instead of the spheres or plates, A and B, we may take the coatings of a Leyden jar with the same result, and in place of the machine, which is a high frequency alternator preferably, because it is more suitable for the experiment, and also for the argument, we may take another Leyden jar or battery of jars. When such jars are discharging through a circuit of low resistance the same is traversed by currents of very high frequency. The plate may now be connected to one of the coatings of the second jar, and when it is brought near to the first jar just previously charged to a high potential from an influence machine, the result is the same as before, and the first jar will discharge through a small air space upon the second being caused to discharge. But both jars and their circuits need not be tuned any closer than a basso profundo is to the note produced by a mosquito, as small sparks will be produced through the air space, or at least the latter will be considerable more strained owing to the setting up of an alternating E.M.F. by induction, which takes place when one of the jars begins to discharge. Again, another error of a similar nature is quite easily made. If the circuits of the two jars are run parallel and close together, and the experiment has been performed of discharging one by the other, and now a coil of wire be added to one of the circuits whereupon the experiment does not succeed, the conclusion that this is due to the fact that the circuits are now not tuned, would be far from being safe. For the two circuits act as condenser coatings and the addition of the coil to one of them is equivalent to bridging them, at the point where the coil is placed, by a small condenser, and the effect of the latter might be to prevent the spark from jumping through the discharge space by diminishing the alternating E.M.F. acting across the same. All these remarks, and many more which might be added but for fear of wandering too far from the subject, are made with the pardonable intention of cautioning the unsuspecting student, who might gain an entirely unwarranted opinion of his skill when seeing every experiment succeed, but they are in no way thrust upon the experienced as novel observations.

In order to make reliable observations of electric resonance effects it is very desirable, if not necessary, to employ an alternator giving currents which rise and fall harmonically, as in working with make and break currents the observations are not always trustworthy, since many phenomena which depend on the rate of change may be produced with frequencies widely different. Even when making such observations with an alternator one is apt to be mistaken. When a circuit is connected to an alternator there are an infinite number of values for capacity and self-induction which, in conjunction, will satisfy the condition of resonance. So there are in mechanics an infinite number of tuning forks which will respond to a note of a certain pitch, or loaded springs which have a definite period of vibration. But the resonance will be most perfectly attained in that case in which the motion is effected with the greatest freedom. Now in mechanics, considering the vibration in the common medium—that is, air—it is of comparatively little importance whether one tuning fork be somewhat larger than another, because the losses in the air are not very considerable. One may, of course, enclose a tuning-fork in an exhausted vessel and by thus reducing the air resistance to a minimum obtain better resonant action. Still the difference would not be very great. But it would make a great difference if the tuning fork were immersed in mercury. In the electrical vibration it is of enormous importance to arrange the conditions so that the vibration is effected with the greatest freedom. The magnitude of the resonance effect depends, under otherwise equal conditions, on the quantity of electricity set in motion or on the strength of the current driven through the circuit. But the circuit opposes the passage of the currents by reason of its impedance, and therefore to secure the best action it is necessary to reduce

* A lecture delivered before the Franklin Institute, at Philadelphia, February 24, 1893; and, before the National Electric Light Association, at St. Louis, Mo., March 1, 1893.

the impedance to a minimum. It is impossible to overcome it entirely, but merely in part for ohmic resistance cannot be overcome. But when the frequency of the impulses is very great, the flow of the current is practically determined by self induction. Now self induction can be overcome by combining it with capacity. If the relation between these is such that at the frequency used they annul each other that is, have such values as to satisfy the condition of resonance and the greatest quantity of electricity is made to flow through the external circuit then the best result is obtained. It is simpler and safer to join the condenser in series with the self induction. It is clear that in such combinations there will be, for a given frequency, and considering only the fundamental vibration, values which will give the best result with the condenser in shunt to the self induction coil; of course more such values than with the condenser in series. But practical conditions determine the selection In the latter case in performing the experiments one may take a small self induction and a large capacity or a small capacity and a large self induction, but the latter is preferable, because it is inconvenient to adjust a large capacity by small steps. By taking a coil with a very large self induction the critical capacity is reduced to a very small value, and the capacity of the coil itself may be sufficient. It is easy, especially by observing certain artifices, to wind a coil through which the impedance will be reduced to the value of the ohmic resistance only and for any coil there is, of course a frequency at which the maximum current will be made to pass through the coil. The observation of the relation between self induction, capacity, and frequency is becoming important in the operation of alternate current apparatus, such as transformers or motors, because by a judicious determination of the elements the employment of an expensive condenser becomes unnecessary. Thus it is possible to pass through the coils of an alternating current motor under the normal working conditions the required current with a low E.M.F., and do away entirely with the false current, and the larger the motor the easier such a plan becomes practicable; but it is necessary for this to employ currents of very high potential or high frequency.



Plan followed in Observing the Effects of Resonance.

In Fig. 20 I. is shown a plan which has been followed in the study of the resonance effects by means of a high frequency alternator. C is a coil of many turns, which is divided in small separate sections for the purposes of adjustment The final adjustment was made sometimes with a few thin iron wires (though this is not always advisable), or with a closed secondary. The coil, C is connected with one of its ends to the line, L, from the alternator, G, and with the other end to one of the plates, c, of a condenser, $c\,c_1$, the plate, c_1, of the latter being connected to a much larger plate, P_1. In this manner both capacity and self induction were adjusted to suit the dynamo frequency.

(To be continued.)

BOROUGH OF BOLTON.

The following are the regulations in connection with the supply of electricity to houses and other premises:

Application for Supply.—Persons requiring a supply of electricity must fill up and sign an application form, giving particulars as to the number and power of lamps proposed to be fixed, and approximately the maximum number likely to be in use at any one time. Also particulars of any other intended use of the current. Forms of application may be obtained at the office of the borough electrical engineer, and should be returned to him, duly filled up, at least 14 days before the supply is required

Character of Supply.—The Corporation will supply an alternating current of about 5,500 complete periods or alternations per minute, and at a mean pressure of 100 volts at the main cut out box.

Three Wire System.—The Corporation reserves to itself the right of supplying any building containing more than 150 lamps of 16 c.p. (or their equivalent), or requiring a large and varied amount of current, at a mean pressure of 200 volts at the main cut-out box, the circuits being subdivided to 100 volts each on the three-wire system. In any case such a building must be wired in at least two entirely distinct circuits, and these should be so arranged that as equal a demand as possible will take place on each.

Wiring.—The whole of the internal wiring and fittings should be carried out by a responsible firm, and must be in accordance with the current rules of the Phœnix Fire Office, and of any other regulations which the Corporation may require

Conductors.—No conductors used shall carry a current greater than 1,000 amperes per square inch of their cross section, and the size of the conductors must be so proportioned that the fall of pressure between the main cut-out box and the farthest lamp shall not exceed 2 per cent. when the maximum number of lamps are on. All conductors to be highly insulated with pure and vulcanised indiarubber, braid and compound, to give a minimum insulation resistance of 300 megohms per mile Lead covered cables are not to be used unless concentric, and in any case not without the special permission in writing of the borough electrical engineer Where metal tubes are used as a protection, both conductors must be placed together in the same tube, which should be of sufficient size to prevent damage in drawing in or out. Under no circumstances whatever are staples or metal saddles to be used to fasten down conductors

Samples.—The Corporation, through their electrical engineer, may require samples of the various wires and cables proposed to be used, with a statement of the maximum current to be sent through each.

Arc Lamps.—When arc lamps are used they should be specially made to burn with alternating currents of the stated periodicity, and a choking coil must be used in each circuit instead of a resistance. The type of arc lamp, choking coil, etc., must be approved by the borough electrical engineer before being used.

Motors and other Apparatus.—Any apparatus not used for ordinary lighting purposes such as motors, regulating switches, resistances, choking coils, heating appliances, etc.—must be approved by the borough electrical engineer before being used.

Gas Fittings.—Gas fittings must not be used for the support of electrical lamps or wires, unless the gas supply is entirely cut off and the fittings are thoroughly insulated from "earth." Special permission, however, may be given for a modification of this rule under certain circumstances.

Main Cut-out Box and Meter.—The Corporation will supply and fix a main cut-out box, and bring their service mains to it free of charge when the distance from the nearest distributing mains does not exceed 60ft. The house mains must be brought to the cut-out box by the consumer, but connection thereto is only to be made by the Corporation officials. Sufficient cable must be left for the meter connection The Corporation will supply meters at fixed rentals, and reserves to itself the right of deciding upon the positions of all meters. When the householder has made proper application for the supply of current, the borough electrical engineer, or his representative, will, if desired, point out the position to be occupied by the main cut out box and meter.

Main Switch.—A double pole switch must be fixed by the consumer in each circuit of the house mains, and on the consumer's side of the meter. Such switches to be securely protected, and to be of a type approved by the borough electrical engineer.

Testing.—No building will be supplied with current until the wiring has been tested and passed by the borough electrical engineer. One test will be made free of charge. At least 24 hours' notice must be given, in writing, to the engineer before a test can be made, and the engineer will then appoint a time. The contractor's representative should be present at the time appointed. The whole work must be completed with fuses in and lamps fixed before a test can be made. If the work be not ready for testing, or should it fail to pass test, a fee of 10s. 6d. must be paid at the office of the electrical engineer before any further test can be made. To avoid misunderstandings with their clients, contractors are advised to test the work themselves before giving notice to the Corporation

Refusal to Supply.—The Corporation may refuse to supply current to any building if (1) the work be not carried out in accordance with these regulations; (2) the whole of the work be not completed, and the fittings permanently fixed; (3) when tested with a continuous current of 100 volts pressure, the insulation resistance of any circuit falls below the following—viz.,

$$\text{Insulation resistance in ohms} = \frac{15,000\,000}{\text{Max. current in amperes}}.$$

This applies to the insulation resistance measured either between the circuit and "earth," or between the circuit and any other circuit.

Leakage.—The Corporation reserves to itself the right at any time, and if necessary without notice, to cut off the supply to the whole or any part of the building, if the insulation becomes defective, or the work otherwise unsafe.

Additional Lights.—If alterations to the wiring, or additional lamps be contemplated, notice must be given in writing to the borough electrical engineer, and such additional work must be tested and passed by him before current is supplied to the altered or new circuits. Non-compliance with this rule will render the whole supply liable to be cut off

Access for Inspection.—Free access must be allowed to the premises at all reasonable times to the proper officers of the Corporation to examine, test, or inspect in any way they may deem necessary, the wiring, fittings meters, and all other matters connected with the electric supply, and all reasonable and suitable facilities must be afforded by the consumer to the officers of the Corporation to enable them to do so.

General Conditions.

The supply of electricity will be subject to the regulations issued from time to time by the Bolton Corporation and authorised by the Bolton Electric Lighting Order, 1891

Current will be charged at the following rates per Board of Trade unit viz. For any consumption above 12½ B.T. units, per 16 c.p. lamp (or equivalent) fixed, per quarter 5½d. per B.T. unit; between 10 and 12½ units, 6d. per unit; between 7½ and 10 units, 6½d. per unit, between 5 and 7½ units, 7d. per unit; between 2½ and 5 units 7½d. per unit, below 2½ units, 8d. per unit.

One B.T. unit is equal to 1,000 watts consumed in one hour. A 16 c.p. incandescent lamp requires 60 watts (approx.), and will thus consume one B.T. unit in $\frac{1000}{60}$ = about 16⅔ hours

Examples.—A customer having 20 16 c.p. incandescent lamps fixed, and using 220 B.T. units per quarter, would be charged at

the rate of 6d per B.T. unit. A customer having four arc lamps fixed, each taking 600 watts (or equivalent to 10 16 c p incandescent lamps each), and using 650 B T. units per quarter, would be charged at the rate of 5½d per B T unit.

Meters will be charged for at the following rentals viz., for 15 16 c p. lamps or their equivalent, 2s. per quarter; for 40 ditto, 2s. 9d per quarter; for 80 ditto, 3s 3d per quarter; for 160 ditto, 4s. per quarter A discount of 2½ per cent will be allowed on all accounts paid within 21 days of the date thereof.

Application Form for Supply of Electricity

BOLTON CORPORATION ELECTRICITY SUPPLY.
Bolton Electric Lighting Order, 1891

To the Bolton Corporation —Please supply electricity to the undermentioned premises and for the following purposes—viz.:

Incandescent Lamps.

Candle power	8	16	32	50
Number fixed				
Maximum number at one time.				

Arc Lamps.

Number fixed			
Current in amperes			
Singly or in pairs			

Note.—Arc lamps may be burned in pairs from the supply mains. If single lamps are joined direct to the mains it must be so stated.

Other Purposes.

Class of apparatus			
Number fixed			
Current in amperes.			

Name of wiring contractor
Signed
Address
Premises to be supplied
Date 18

REPORT OF JOINT COMMITTEE ON ELECTRIC POWERS (PROTECTIVE CLAUSES).

The committee have taken evidence from Sir Courtenay Boyle, K C B, from Mr. Preece, engineer in chief and electrician to the Post Office, from Major Cardew, electrical adviser to the Board of Trade, and the Astronomer Royal. Counsel appeared before them on behalf of: 1. The National Telephone Company 2. The railway companies. 3. Electric tramway companies, and electric underground railway companies. 4 Electric lighting companies. 5. Municipal corporations, England and Scotland. 6. Tramway Institute of Great Britain and Ireland. 7. Gas and water companies. Her Majesty's Postmaster General was also represented but not by counsel.

The committee have heard all the witnesses tendered by the several parties, and have agreed upon the following clause, to be inserted in all Bills and provisional orders which authorise the undertakers, other than electric lighting undertakers, to use large electric currents—viz.:

Clause to be inserted in all Bills and provisional orders which authorise any company, corporation, or person, collectively referred to as "the undertakers," to use larger electric currents for other than electric lighting purposes. (Some modifications of form may be required to meet the circumstances of particular cases.)

(1) The undertakers shall, in the use of electric power under the provisions of this Act (order) employ either insulated returns or uninsulated metallic returns of low resistance (This clause not to apply in the case of railways, tramways, or tram roads in which the motive power is entirely self contained.)

(2) The undertakers shall take all reasonable precautions in constructing, placing and maintaining their electric lines and circuits, and other works of all descriptions, and also in working their undertaking so as not injuriously to affect, by fusion or electrolytic action, any gas or water pipes, or other metallic pipes, structures, or substances.

(3) The exercise of the powers by this Act (order) conferred with respect to the use of electric power shall be subject to the regulations set forth in the schedule to this Act (order), and to any regulations which may be added thereto or substituted therefor, respectively, by any order which the Board of Trade may, and which they are hereby empowered to make from time to time, as or when they may think fit, for regulating the employment of insulated returns or of uninsulated metallic returns of low resistance, for preventing fusion or injurious electrolytic action of or on gas or water pipes, or other metallic pipes, structures, or substances, and for minimising, as far as is reasonably practicable, injurious interference with the electric wires, lines, and apparatus of other parties and the currents therein, whether such lines do or do not use the earth as a return.

(4) The undertakers using electric power contrary to the provisions of this Act (order), or to any of the regulations set forth in the schedule to this Act (order), or to any regulation added thereto or substituted therefor by any order made by the Board of Trade under the authority of this Act (order), shall, for every such offence, be subject to a penalty not exceeding £10, and also in the case of a continuing offence to a further penalty not exceeding £5 for every day during which such offence continues after conviction thereof. Provided always that, whether any such penalty has been recovered or not, the Board of Trade, in case in their opinion the undertakers in the use of electric power under the authority of this Act (order) have made default in complying with the provisions of this Act (order), or with any of the regulations set forth in the schedule to this Act (order), or with any regulation which may have been added thereto or substituted therefor as aforesaid, may by order direct the undertakers to cease to use electric power, and thereupon the undertakers shall cease to use electric power, and shall not again use the same, unless with the authority of the Board of Trade, and in every such case the Board of Trade shall make a special report to Parliament notifying the making of such order.

(5) The undertakers shall take all reasonable and proper precautions in constructing, placing, and maintaining their electric lines, circuits, and other works of any description, and in using their electric lines, circuits, and other works, so as not injuriously to interfere with the working of any wire, line, or apparatus, from time to time used for the purpose of transmitting electric power, or of telegraphic, telephonic, or electric signalling communication, or the currents in such wire, line, or apparatus: Provided always that the undertakers shall be deemed to take all such reasonable and proper precautions as aforesaid, if and so long as they adopt and employ at the option of the undertakers, either such insulated returns or such uninsulated metallic returns of low resistance, and such other means of preventing injurious interference with the electric wires, lines, and apparatus of other parties, and the currents therein, as the Board of Trade shall direct, and in giving such directions the Board shall have regard to the expense involved, and to the effect thereof upon the commercial prospects of the undertaking. Provided also that at the expiration of —— years from the passing of this Act (order), nothing in this sub section shall operate to give any right of action in respect of or to protect any electric wires, lines, or apparatus, or the currents therein, unless in the construction, erection, maintaining, and working of such wires, lines, and apparatus, all reasonable and proper precautions, including the use of an insulated return, have been taken to prevent injurious interference therewith, and with the currents therein, by or from other electric currents. If any difference arises between the undertakers and any other party with respect to anything in this sub section contained, such difference shall, unless the parties otherwise agree, be determined by the Board of Trade, or at the option of the Board by an arbitrator to be appointed by the Board; and the costs of such determination shall be in the discretion of the Board, or of the arbitrator, as the case may be.

(6) Nothing in this section shall apply to the use of any electric line, circuit, or work of any company, corporation, or person authorised by Act of Parliament, or provisional order confirmed by Parliament, to supply energy for electric lighting purposes, so far as such use is limited to such purposes.

The committee have also agreed upon the following resolutions in the nature of recommendations—viz.:

(1) The committee having regard to the evidence before them, are of opinion that it is not in the present state of electrical science to the interest of the public to insist upon electrical tramways using an insulated return conductor, and that such insistance would retard the development of electric traction.

(2) The chief objections which have been urged before the committee to an uninsulated return conductor are, first, the interference by leakage and induction with telephones; secondly, the interference by leakage and induction with railway signals; thirdly, the damage to systems of gas and water pipes by the action of leakage currents.

(3) They are of opinion that the best known means of overcoming the first of these disturbances is by providing an insulated return conductor for the telephones, and they have the less hesitation in recommending this course as the evidence shows that telephone construction is already tending in this direction, and that better results are secured to the public by the use of a twisted metallic circuit insulated entirely from the earth.

(4) The second objection deserves serious consideration on account of the danger to the public, but the committee are of opinion that the disturbance may be remedied at comparatively small expense by the adoption of an insulated metallic return by the railway companies.

(5) They consider that, although electric tramway and electric railway companies should be allowed to use the wheels of carriages and the rails to complete the electric circuit, the currents should be produced and used in such a manner as to mitigate as far as is practicable any injurious effect to telephonic communication.

(6) The committee are of opinion that it is desirable in every way to facilitate the use of complete insulated metallic circuits for telephones, and for this end they recommend that statutory powers be granted enabling telephone undertakers to lay their wires underground.

(7) The danger from fusion or electrolytic action appears to the committee to have arisen from a faulty system of constructing

electric tramways, and they are of opinion that it can be reduced by improved methods of construction so as to be practically negligible.

(8) The committee therefore recommend that the Board of Trade shall, in virtue of the powers to be conferred upon them by each Act or order, make regulations to secure the best system of working electric tramways and railways, having regard to the expense involved by the carrying out of such regulations, and to the effect thereof upon the commercial prospects of the undertaking. The regulations to provide, *inter alia* (a) That a return conductor, if in contact with the ground, shall be of such section and resistance as to have no difference of potential sufficient to set up injurious leakage currents in the earth. (b) That, both with regard to the structure of the line and to the method of generation and use of the electrical current, everything shall be maintained up to the standard required by the Board of Trade; but, if the regulations are altered after the use of electric power on the line has been sanctioned, the undertakers shall not be required to alter the structure or method of working of the line to conform to the more recent regulations, except for the public safety, or unless it shall be proved to the satisfaction of the Board of Trade that any system of metallic pipes or structures is being injured by the action of electricity escaping from the conductors, or for purposes other than public safety or injury to pipes or structures which the Board may think right, provided that the alterations do not in such last case cause substantial additional expenditure. (c) That all such electrical tests shall be applied to the line by the undertakers as the Board of Trade may think necessary, and that a record of these tests shall be kept for the information of the Board of Trade. (d) That the Board of Trade shall have all reasonable facilities for making any tests they may think necessary, in addition to those recorded by the undertakers to enable them to ensure the maintenance of satisfactory conditions.

(9) That the committee regards with apprehension a large extension of the system of overhead wires in crowded centres.

(10) It appears to the committee to be just that undertakers proposing to use large currents should be required to give ample notice to those using small currents to enable them to protect themselves by insulation, and that with this view, and in reference to the clause agreed upon, a period of two years may fairly be allowed to telephone and telegraph companies from the date of the passing of any Act (order).

LEGAL INTELLIGENCE.

BLACKIE v. THE ELECTRICITY SUPPLY CORPORATION.

This was an action before Mr Justice Cave and a special jury, on Friday, brought by a clockmaker and jeweller carrying on business at 392, Strand, for damages and an injunction restraining the defendants from carrying on their business so as to cause a nuisance. The defendants' central station is situated in Bull Inn court, Strand, about 150ft. from the back of the plaintiff's shop. The defendants' machinery consists of 10 engines and dynamos, five of which are of 200 h.p. each. Two engines are in the basement on cement concrete foundations 6ft. thick. The other engines rest upon the floor of the building, constructed of iron girders supporting a bed of concrete 3ft. thick. The floor is supported by iron stanchions resting upon concrete foundations let into the ground 6ft. thick. The defendants at the busiest time of the day work four of the engines and dynamos, producing a current of from 2,000 to 3,000 amperes at a pressure of 100 volts. The engines are not worked up to their full load, but are generally run at about half load, more engines being employed to produce the necessary current. The plaintiff was called in support of his case, and stated that he first felt vibration in his premises in September, 1891, which he attributed to the working of the defendants' engines. The vibration affected his regulator so that he had to send his watches and chronometers to be regulated elsewhere. The housekeeper and his wife were also called and stated that the vibration was considerable during the evening, shaking the windows of the house; that the vibration occurred on July 6, when all traffic was stopped in the Strand. Other witnesses from the neighbourhood were called, and said they had felt vibration which they thought came from the defendants' works. For the defence witnesses were called who had visited the plaintiff's premises, and stated that the vibration was not felt in the house, but only on the roof, which was only appreciable by means of the most sensitive instruments.

Mr. Justice Cave, in summing up said that when a person made use of his land in a way differing from others round about he must take care not to inflict injury or discomfort on others. In this case the defendants clearly were not doing what people all round were doing. The test was, had the defendants done anything which had made the enjoyment of the plaintiff's house uncomfortable, or had they seriously interfered with the plaintiff's carrying on his business? If either had happened, then the plaintiff was entitled to a verdict. If neither had happened, then the defendants were entitled to a verdict. It was said that the defendants had communicated vibration to plaintiff's property. If they had done that so as to substantially interfere with his comfort or his business, then the plaintiff would be entitled to a verdict. The plaintiff had two strings to his bow—first, an alleged interference with his comfort; secondly, an interference with his business—namely, that his regulator was affected, and he had to get his watches regulated elsewhere at considerable cost. It was not easy to make out what damage had been suffered.

The jury found that there was vibration, but that the vibration was so slight that the damages were inappreciable.

The learned **Judge** held that was a verdict for the defendants, and judgment was entered accordingly.

Mr Bousfield, Q.C., Mr Morton Smith, and Mr. Bodilly were for the plaintiff; Mr Moulton, Q.C., Mr English Harrison, and Mr. A. B. Terrell for the defendants.

COMPANIES' MEETINGS.

NATIONAL TELEPHONE COMPANY, LIMITED.

On Tuesday, Mr. J. Staats Forbes (president) occupied the chair at the thirteenth ordinary general meeting of this Company, held at the Cannon street Hotel, E.C. The Secretary (Mr. A. Anns) read the notice convening the assembly, and the report and accounts were taken as read.

The **Chairman**, in moving the adoption of the report and accounts, said it would interest them to learn that the partners in the undertaking numbered 6,721 ordinary and 1,820 debenture holders, or 8,541 in all. The year completed had been one of progress and one of spending money pretty freely. Referring to No. 1 account, they would see how it stood at the end of last year, and he drew attention to one or two points about it, especially as to how it stood now, what the money had been spent upon, how it had been raised, and how it affected the question of net profit, and therefore dividends. They would observe on the debtor side very considerable additions in the purchase of several undertakings. As they knew, the policy of the Directors had been during the past few years to bring into the brotherhood all the subsidiary outside companies. The amalgamation of the three great companies which became the National, had showed them the wisdom of fusion so strongly that they had from time to time induced those other companies which were less important to come in, with the result that now they were practically all absorbed. The Western Counties and South Wales was down for £277,607, the Sheffield Telephone Exchange and Electric Light Company, of which they had bought only the telephone business for £38,696, and some other minor companies, some in being, and some threatening to be in being, but not very important. Those several companies together made up the sum of £345,776, and they had brought in areas not previously within the government of the National Company; but the parent concern—the combination of the companies described as the National Company—they, like the others, were progressing. The subscribers grew, and the peculiarity of the business was that every single new subscriber meant a special outlay for himself. It was somewhat different to some other enterprises, where the original outlay, for whatever purpose, involved a considerable first cost, but when the machine was started its capacity was a very long time being exhausted; but in the telephone business every subscriber could not be connected without money down at first. That money had to be found, and therefore it bore interest some few months in advance of the completion of the work which produced the income. The amounts expended upon construction and other capital charges were £305,799. They would therefore see that a very large sum of money had been spent in the year—£651,575—and that money had had to be provided. It was provided by the issue of certain of their stocks, in ordinary shares and third preference, and in round figures it came to £595,000. Those subscriptions had brought upon the year a certain amount of charge which made its influence felt when they came to the net revenue account. The Directors called attention specially to the large expenditure for the acquisition of the other companies, and they were quite prepared to take the responsibility for having done it. There were some other charges to which he would refer later, but having got into the minds of the proprietors that the Directors had spent a considerable sum of money, that they had had to issue stock to meet it, and that that stock, of course, added considerably to the net revenue account, he would then pass to the results. Money expended in that way was not immediately productive—it took a certain time to develop. However, he did not think they had done badly in the result, because if they turned to the net revenue account they would there see what had taken place. There had been a considerable addition to the Company's business. At the last meeting he had had occasion to impress upon the shareholders the necessity for finding a factor—something which would enable them to measure the way and results. The Directors had tried in this undertaking to find some factor to form a standard of comparison, and the nearest thing was wires, not subscribers. It was true that the mass of the wires served an individual subscriber, but some subscribers used more than one wire, some two or three, but each wire entailed specific expenditure, and the multiplication of wires meant a multiplication of business, and that meant operating, and therefore a wire might be looked upon as an instrument used by individual persons; and it was the nearest thing they could find by analogy to a train mile in railways. Therefore they were to deal with wires. Now the progress of wires was one measure of measuring the progress of business. They had in the year increased from 47,878 wires to 59,031—that meant an advance of 11,153. He must qualify that by reminding them that they had brought in during that period the corpus of the Western Telephone Company, who had, when they took over the company, about 4,000 wires. Deducting that, it showed that the normal progress had not been 11,153, but 7,153. The Directors had the means of testing the cost of putting on a subscriber. If they divided the figure £305,799 for construction

of exchange, trunk and private lines, they would see that the average was something like £42 per subscriber or per wire. Some people had an idea that it could be done for much less, but the Directors knew. They believed in the undertaking and the experience and the skill at their command enabled them to determine exactly the right thing to do and to do it in the most economical and best fashion and it worked out at £42 per wire. Now about the results, for which he would take them to the paragraphs of the report. The income had reached £583,590, which was an increase of £119,848 over the preceding year. He would remind them there that both the Sheffield Company, and especially the Western Company, were included in that amount, and their income which subsisted last year was incorporated bodily in that, and it was not attributed to any abnormal increase of the United Company; but they had contributed a fair proportion to that increase. That increase did not show altogether the advance they had made in the business. The next item was extremely important; it was the rentals carried forward this year, amounting to £285,020, as compared with £234,370, or an increase of £50,649. Their money was paid in advance, and they made contracts from day to day, but taking a year's subscriptions, it was obvious that a portion overlapped a portion of the following year, so that in the year they had received in cash £50,649 more than in the corresponding year for services falling upon the coming year, but that was an increase of income already in their pockets. Now the working expenses followed in all ways the increase of the business; they were very large in proportion to the increase of money—£75,392 out of £119,848. That arose from one or two causes. Like the income of the Western and other companies brought in to swell the gross receipts, the working expenses of those new areas came in to swell the working expenses; and with this disadvantage in comparison, that those areas were more sparsely populated, the income per subscriber was relatively less, and the expenditure relatively more, than in the bigger undertaking. Thus they diluted the averages. They were working at an enhanced percentage of the gross income because they had added the gross income of those companies where the working expenses bore a higher proportion than their own. Then again, of course, the older the institution, the more compact, the more it was developed, and those outlying areas were not quite developed to the extent of the parent districts, but all that was for the future. There was perceptible development. There were certain considerable fixed charges which were not affected by there being 1,000 or 2,000 more subscribers. They did not add any more to the cost of working, and to that extent they kept dropping a portion on those charges. The net result for the year, after deducting Post Office royalties, amounted to £54,220. That was a pretty stiff tax to levy on a company like that. The Company were always being pulled to pieces because they did not reduce the tariff. The reduction of tariff meant that the expense was not diminished. The undertaking, although very sound, and its future might be regarded as assured, yet the difference of a very small reduction might mean a very large effect upon the dividends. If they picked those figures to pieces, they would find that they were not now so far in excess of charge when it was compared with the cost, as to be able to make any great reduction. People somehow who did not know were always ready to dictate what they ought to do. They were not concerned as to whether it was wise or whether it paid to do it. The Company were held up to odium because they were so enormously dear, and contrasts were drawn—New York, Boston, St. Petersburg, Berlin, anywhere where the circumstances were entirely different, so different as to produce a very serious effect upon the profit. First of all, about what they did that they were not progressive. Well, he had some figures that were eloquent. This Company was fused, and their first year's business was in 1890. The average receipt throughout the area served by the Company was £14. 11s. 4d. in 1890; in 1893 the average was reduced to £9. 17s. 9d., and he would venture to say that there was no comparison between that charge and the charge in any other great city in Europe, even including Berlin. In 1890 the proportion of expenses to earnings was 49½ per cent., whilst during the past year it had been 62·9 per cent. The reduction went out of their pockets. The number of lines had increased from 26,086 to 59,031. They knew that the dividend had been 6 per cent. Of course they could have paid 6 per cent. this year, but for reasons it was considered wiser to pay 5 per cent.; but was 6 per cent. an unreasonable return for such a venture as their undertaking? It could not be compared with Paris, Vienna, St. Petersburg, or any other city cast in their teeth. The amount of the subscriptions there did seem less; in fact, they were much larger in some places, and they were larger notwithstanding they were free from things which affected the National Company most seriously. As far as he knew, in Berlin and Paris, and in the great cities where the telephone enterprises had fallen into the hands of the State, there were no wayleaves, there was certainly no 10 per cent. on the gross receipts payable to the State at the risk of somebody else. He was sure that many of those were worked at a loss. As far as the London charge of £20 was concerned, that was perfectly illusory. It was quite true that they had some subscribers who paid that, but if they subscribed for a term they got it for less. Then, to attach a subscriber to the telephone, they must put down £42. It was not unreasonable to charge a high rate for a short tenure, but that £20 was quite a fallacy, because the average during the past year had been £15. 0s. 7d. in London. This could not be compared in the same sense with other cities. The whole area of London was included in the subscription. In Berlin, Paris, and other cities the State did not pay much for wayleaves; in London they paid £1. 4s. for every subscriber, and they paid £1. 6s. 9d. royalty to the Post Office. Thus there was £2. 10s. out of the £15s. 0s. 7d., and if that was deducted from the £15, he maintained, looking at the area covered and the circumstances under which the business was carried on, London was the cheapest city in the world. Leaving London out of consideration, the charge all over the country for an annual subscription to the wires averaged £8. 16s. 10d., but including London it was £9. 16s. 10d. In each of those cases the same thing held good about wayleaves and Post Office royalty; take those off, and the cost was materially diminished, and that they were bound to do to make a fair comparison. The Company deserved to be understood, and they were entitled to some fair comparison with what they did and what their models did. The net results of the year, deducting those royalties, amounted to £30,475. They proposed to pay on the major quantity of orders 5 per cent.; they could have paid another 1 per cent., but they had had to consider the character of the business, whether it was not a prudent thing to pay a dividend that was not so bad in these times, and which as time went on and consols diminished in value would be brilliant, and would be something in the nature of a permanent 5 per cent., with a strong reserve. That had appeared to have excited a difference of opinion, which he detailed by reading two letters from shareholders. Considering all the circumstances of the case, the Directors concluded that it was their duty to recommend the acceptance of the reduction of dividend, but with the great enhancement of the security of the property. Coming to deal with general matters, he first referred to paragraph 8. That was a story that had to be told. That was a case in which many people signed a paper and were promised the impossible, and they believed it; but the very people who promoted that company (the New Telephone Company), when they sat down and under the inspiration and the knowledge of the National Telephone Company appreciated their position, they saw the wisdom of coming to terms with the National, who, in turn, thought it prudent to come to terms with the former, and that paragraph exhausted the whole story. They were in the midst of those negotiations under which they were to become partners when the new policy of the Government was launched, and the late Duke of Marlborough was pretty well puzzled what to do about the Government, and so was the speaker. One of the oddest things was that the competitor of this Company, the duke, was immediately brought into close connection with the Directors to see what could be done. What had to be done was to fuse it with this Company. They had had a touch of competition at Manchester: the rates were lower, but the convenience of the public was not assured. The Post Office had the right of taking over the telephone company any day they liked by agreement. The Post Office agreed that the most difficult, costly, and sensitive part of the business should be committed to a company, but they would keep the arterial process in their own hands. So far as the Government policy went, it seemed to be one of disruption. He referred to the negotiations proceeding with the Post Office for the purchase of the Company's trunk lines, and said there would be conflict, and without suggesting that anyone connected with the business would be influenced in the slightest degree to protect the telegraph revenue, they had to submit their judgment to theirs, and certain things they would now have to refer to the Post Office. That was one matter that was acting to obstruct the development of telephones. The Post Office held the trunk lines, and intercommunication was to go on through that medium. The National would pick up the business, the Post Office would send it, and the National Company would drop it again. That agreement would be in their hands in a short time, and he hoped the public would like it. He then referred to the introduction of new directors Lord Balfour of Burleigh and Sir Albert K. Rollit, M.P., and moved the adoption of the report and accounts, and the payments of the dividends recommended.

The **Right Hon. Lord Balfour of Burleigh** seconded the motion.

The **Chairman**, in reply to questions, observed that the amount of £397,580 represented the cost of acquiring the shares in the New Telephone Company, and what they held in it. The reserve fund was invested in the Company's business, and as it grew larger they would have to consider whether to invest it in securities or not. The Company were informed of the desire of the Corporation of Glasgow to establish a local telephone service, but the working of it was a matter that could be predicted. They knew what had happened in Manchester, where subscribers found the necessity of subscribing to two exchanges, instead of one, to get what they wanted. That must be so, and the Company had no intention of vacating Glasgow, where, if the Postmaster-General granted a license, the same difficulties would be met with as at Manchester—a divided service, a certain loss on the undertaking. He thought the Government would have to buy up the telephones long before the license expired, and that they would have to make some provision for what might arise; hence the necessity for a moderate dividend and a big reserve. He then put the resolution, which was unanimously adopted.

The retiring Directors (Lord Balfour of Burleigh, Mr. C. Swain Agnew, Mr. G. Hunter Robertson, and Sir Albert Rollit, M.P.) were re-elected, and Messrs. Welton, Jones, and Co., the auditors, were reappointed.

A vote of thanks to the chairman terminated the proceedings.

ELECTRIC CONSTRUCTION CORPORATION, LIMITED.

An extraordinary general meeting of this Company was held yesterday at the Cannon-street Hotel, E.C., under the presidency of Sir Daniel Cooper, Bart. (chairman), to confirm the resolutions passed at the previous meeting for the voluntary liquidation and reconstruction of the Company, and which resolutions were printed in our issue of June 30.

The Secretary (Mr. J. Gray) read the notice and the resolutions passed at the previous gathering.

The **Chairman**, after a brief speech, explaining the resolutions, moved them.

Mr. Barclay seconded the resolutions, which were unanimously adopted.

The **Chairman** then moved, and **Mr. Plunkett** seconded the appointment of Mr. P. E. Beechcroft and Mr. E. Garcke as liquidators. This motion was adopted, and the proceedings terminated.

EASTERN TELEGRAPH COMPANY, LIMITED.

The forty-second half-yearly ordinary general meeting took place on the 13th inst. at Winchester House, Sir John Pender presiding.

In moving the adoption of the report and accounts, the **Chairman** stated that the gross revenue for the half-year ending 31st March last amounted to £372,852, being a decrease of £9,355 as compared with the same period of the previous year. The reduction in the gross revenue was due to their having received £17,700 from their investment in the Eastern and South African Telegraph Company, as against £29,580 in the corresponding period of the previous year. The ordinary expenses for the half-year totalled £102,499, as against £105,820 in the same period of 1892. After making provision for interest on debentures, debenture stock, and preference shares, they were able to propose the usual final dividend of 1¼ per cent. and a bonus of 1¼ per cent. thus making, with the interim dividends already paid, a total distribution of 6¼ per cent. for the year ended March last, and to carry £88,000 to the reserve fund as against £68,000 in the previous year. He thought they had materially improved their position during the half-year, and then moved the adoption of the report and the payment of the dividends and bonus recommended.

The **Marquis of Tweeddale** seconded the motion, which was adopted.

WEST AFRICAN TELEGRAPH COMPANY, LIMITED.

The eighth ordinary general meeting of this Company was held on the 13th inst. at the offices, Winchester House, E.C., Sir John Pender, chairman, presiding.

The report, which was taken as read, stated that the revenue for the year ending December 31 last amounted to £60,922, against which £20,018 was charged for ordinary expenses, £13,964 for expenditure relating to repairs of cables, etc., and £801 for income tax, leaving a balance of £26,137. From this amount was deducted £23,726 (being for interest on debentures £13,060, and for sinking fund £10,666), leaving a balance of £2,411, which it had been decided to carry forward.

In moving the adoption of the report, the **Chairman** expressed regret at the large increased expenditure (£11,000) in cable repairs, and at the further loss of £8,000 on exchange; but the Directors were doing everything possible to minimise the loss in the future. He then moved the adoption of the report and accounts.

Sir Henry C. Mance seconded the motion, which was carried.

BUSINESS NOTES.

Bristol.—Dynamo attendants, strokers, and drivers are required at the Bristol central station.

Glasgow.—The new telephone switchboard, about which so much has been written and said, is now in work.

Cardiff.—It has been decided to make provision for electric light in the new Cardiff museum and free library.

Richmond.—Active steps are being taken by Messrs. Latimer Clark, Muirhead, and Co., at Richmond in extending the street electric mains.

Richmond Fire Calls.—The Corporation of Richmond ask for tenders for fire calls to be laid within the borough. An advertisement appears this week.

Partner.—An electrical engineer (Mr. Bennett, 44, Fishergate, Preston) having completed a large electrical supply station, is wishing to find a partner with capital.

Globe Telegraph and Trust Company.—A balance dividend of 4s. per share is proposed, making a total payment for the year of 4½ per cent., carrying forward a balance of £1,287.

Chester.—Mr. Preece has submitted a report, and assuming the site to be the Hop Pole Paddock, and a low pressure system be adopted, the cost for the initial installation is estimated at £15,000.

Blackpool.—Tenders for wiring and fitting electric lights in the Town Hall and market place at Blackpool are to be sent in by Saturday, the 22nd inst., to Mr. G. Hesketh, borough electrical engineer, Princess-street, Blackpool.

Halifax.—As seen in their advertisements, the Halifax Corporation require tenders for engines, alternators, exciters, and boilers. Those for engines and dynamos are required by 28th inst., and for the boilers by August 4th.

Dorset Asylum.—The tender by Mr. F. M. Newton, of Taunton, has been accepted for the lighting of the Dorset County Asylum. The installation will consist of about 1,000 incandescent lamps. Taunton dynamos will be used, coupled direct to Willans high-speed engines.

Western and Brazilian Telegraph Company.—The receipts of this Company for the week ended July 14, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £2,346.

Eastern Telegraph Company.—This Company notify that the coupons on their 5 per cent. debentures, due August 1 next, will be paid on and after that date at the banking house of Messrs. Glyn, Mills, Currie, and Co., 67, Lombard-street, E.C.

Croydon.—The statement that the Croydon Town Council had resolved to adopt the electric light in the centre of the borough, at an estimated cost of £25,000, is contradicted. The Council deferred consideration of the matter until a future occasion.

Telegraph Construction and Maintenance Company.—The transfer books will be closed from the 17th to the 25th inst. inclusive, preparatory to the payment of an interim dividend of 12s. per share to all shareholders on the register on the 17th inst.

Middlesbrough.—The question of electric lighting is now receiving the attention of the Middlesbrough Corporation, and an Electric Lighting Committee has been appointed to deal with the matter. The borough engineer of Middlesbrough is Mr. E. D. Latham, C.E.

Winchester.—The Town Council of the city of Winchester have appointed Messrs. Morgan Williams and King as consulting engineers to adjudicate in the matter of the award of the premium offered for the best scheme delivered to them for the electric lighting of the city.

Hanley.—At the meeting of the Hanley Town Council, on Tuesday, the Financial Committee recommended that application should be made to the Local Government Board for an order consenting to the creation of stock for amounts, amongst others, of £21,000 for electric lighting.

Oswestry.—At a special meeting of the Oswestry Town Council on Monday it was decided to grant a provisional order to the local electric lighting company, of which the Mayor (Mr. Corrie) is the chairman. The terms to be inserted in the order are similar to the Wrexham and the Altrincham orders.

Hammersmith.—The Electric Light Committee of the Hammersmith Vestry have appointed a sub-committee of 12 to report as to the experiments now proceeding in regard to the destruction of house refuse, and to go into the whole question of electric lighting generally, and to report on these matters.

Anglo-American Telegraph Company.—It has been resolved to declare an interim dividend for the quarter ended June 30 of 12s. 6d. per cent. on the ordinary stock and 25s. per cent. on the preferred stock, less income tax, payable on August 1 to the stockholders registered on the books of the Company on July 10.

Bath.—Mr. Massingham, in consequence of his numerous engagements has resigned the position of managing director of the Bath Electric Lighting and Engineering Company, and the company's chief engineer, Mr. G. F. Metzger, has been appointed general manager. Mr. Massingham remains a director of the company.

Lambeth.—The appointment of the Electric Lighting Committee of the Lambeth Vestry has been held over for a year. The provisional order obtained by the Vestry only extends to next June, and if by that time the Vestry has not laid down electric mains in the trunk roads of the parish, the Board of Trade may revoke the order.

Portsmouth.—Owing to the fact of the Portsmouth Corporation loan for some £200,000 for electric lighting and other purposes, being put on the market at the time the India 3 per cent. stock was asked for, only few applications (for £93,000) were received. The Corporation have decided to communicate with the National Provincial Bank.

Bradford.—A meeting was held on Wednesday at Bradford, at which Lord Kelvin attended to answer questions on the proposed extension of mains. His answers will be put into the form of a supplementary report, corrected by him, and will be placed before the Gas and Electricity Committee. Lord Kelvin approves generally the plan put forward by Mr. Baynes.

Chelsea Electricity Supply Company.—This Company have completed the laying of mains and are now supplying current in the following streets lately added to their area of supply: Cheyne-gardens, Cheyne-walk, Chelsea-embankment, St. Leonard's-terrace, Tedworth-square, Tite-street, Ralston-street, Durham-place, Oakley-street, King's-road. Large additions to plant and further extensions of mains are being made.

Electric Railway from Waterloo to the City.—The Unopposed Bill Committee of the House of Lords last week passed the Bill authorising the construction of an underground electric railway from Waterloo Station to a point in the City almost opposite the Mansion House. No intermediate stations will be placed on this railway between the commencement and termination of the railway. The scheme has already received the sanction of the House of Commons.

Direct United States Cable Company.—The Board have resolved to recommend a final dividend of 3s. 6d. per share, free of income tax, such dividend to be payable on and after the 29th inst., making, with the interim dividends already paid, 3½ per cent. for the year ended June 30 last, and after placing £3,000 to reserve fund account, carrying forward a balance of £819, 2s. 4d. The transfer books of the Company will be closed from July 14 to July 28, both days inclusive.

Lancaster.—Major-General Crozier, R.E., held a Local Government Board enquiry last week into an application made by the Lancaster Town Council for sanction to borrow £25,000, the

estimated cost of a system of electric lighting installation for the borough, to be provided by the Brush Electrical Engineering Company, of London. Only the main streets in the centre of the town are to be lighted at first, but arrangements are being made for additional plant to be put down as required.

Aberdeen Electrical Engineership. The Gas Committee of the Aberdeen Town Council last week considered finally as to their recommendation to the Council on the question of the appointment of an electrical engineer. Prof. Kennedy was present at the meeting, and his recommendation having been considered, the committee agreed to submit the following four names to the Council: John Christi, Glasgow; E. T. Ruthven Murray, Larne; Alfred H. Gibbings, Sussex; and Frederick A. Nixon, London.

Continental Edison Company. The Compagnie Continentale Edison having ceased manufacturing their dynamos and other apparatus in France, has disposed of its works at Ivry sur Seine to the Compagnie de l'Industrie Electrique of Geneva. This latter company has begun the manufacture of Thury dynamos and apparatus in France to satisfy the enquiries and orders received from that country, as the municipal councils will only grant concessions for electric light on condition that all the material is made in France.

The Squire's Engine.—Under this name Messrs. Merryweather have produced a vertical engine and boiler, mounted on a carriage, which can be used, as occasion requires, for driving a dynamo to light the squire's house, chaff cutting for the squire's horse, or, hitched to this same horse, as a fire engine to put out the fire at a hayrick or in one of the houses down in the village. It is the sort of engine a consulting engineer might find useful to specify for those country gentlemen who like their apparatus arranged to kill two birds with one stone.

City and South London Railway Company.—The receipts for the week ending July 16 were £774, against £766 for the same period last year, or an increase of £8. The total receipts for the second half year of 1893 show an increase of £344 over those for the corresponding period of 1892. The accounts for the past half year admit, after paying debenture interest and dividend on the 5 per cent. preference shares, a dividend on the ordinary stock of ¾ per cent., as against ½ per cent. at the corresponding period last year, with £898 carried forward.

European Gas Company. At the annual meeting of the European Gas Company, the chairman, Mr. J. Blacket Gill, said that during the past year he had paid a visit to their stations, accompanied by the general manager, and he noticed that the electric light had gained ground during the last two years. The Company had a large business in the middle of the day with stoves and engines. They had about 38,000 stoves on hire besides 250 gas engines, the result being that about 25 per cent. of their total consumption was in the daytime.

Dublin Tramways. The half yearly meeting of the Dublin United Tramways Company was held on Tuesday. The chairman (Dr. Carte) stated that the traffic receipts for the half year showed an increase of £4,200, and the number of passengers carried, an increase of 900,000. The company were urged by one of the shareholders to employ electric power, and the chairman stated that the company working the tramway between Dublin and Dalkey were applying for power to use electricity, and if the results there proved satisfactory their company would also adopt that plan.

Leeds.—At its meeting last week the Corporate Buildings Committee of the Leeds City Council talked over the desirability of acquiring new plant for working the electric lighting apparatus at the Municipal Offices and the Town Hall. The committee has long been convinced that the existing machinery is totally inadequate for maintaining the requisite amount of illumination and have at last resolved to urge upon the Corporate Property Committee the desirability of purchasing new apparatus. The sum of £10,000 or £12,000 is mentioned as the probable outlay that would be requisite.

Madras Tramways.—The statement that the Government has refused the extension of time asked for by the Madras Tramways Company is confirmed, says the *Indian Engineer*. The company thus loses the concession and forfeits the 10,000 rupees deposit paid to the Municipal Council. It is not known yet what steps the shareholders are likely to take, but it is expected that they will lose all the paid up capital on the four rupees shares. An effort will probably be made to induce the Government to reconsider its decision. The present failure is considered a death-blow to the prospects of any tramways in Madras.

Poplar. The Poplar District Board have received a report from the Works Committee, in which they recommend that the clerk should report to the committee on the subject of electric lighting, in view of the Act of Parliament confirming the Poplar electric lighting order and the position of the Board in the matter. Mr. Booth called attention to a statement made that St. Pancras was making a profit out of the electric light. He thought the committee should have some figures, especially as nothing had been mentioned anywhere about profit from the electric light in St. Pancras. This was agreed to, and the clerk was instructed to report.

Oban. A communication was read at the last meeting of the Oban Town Council from the Caledonian Electric Supply Company, Limited, giving notice that an application was intended to be made on or before December 21 next, by memorial to the Board of Trade, whereby it is proposed to authorise the company to supply electricity for any public or private purpose within the district area comprised within the municipal boundaries of Oban. The meeting considered the proposal as one of great importance, and the letter was remitted to the Lighting Committee with an injunction to give it early consideration. Few towns in the country are so highly rated as Oban in the matter of its gas. Over 8s. per 1,000ft. is rather a stiff figure to pay, especially where there is a large consumption.

Chatsworth. The Duke of Devonshire has decided that Chatsworth is to be lighted with electric light, and after careful consideration, he has accepted the scheme proposed by Mr. Bernard Drake, of Drake and Gorham, Westminster. His proposal is to obtain the whole of the necessary horse power from a large pipe already laid for the supply of the well known Emperor Fountain. He estimates that from this source he can obtain up to 150 h.p., which will amply suffice for all requirements. The turbine house is being built outside the gardens, and in order to avoid an eye sore it will be sunk entirely out of sight. The number of lights to be fixed at present are about 700, which will be ready for use in September. The installation will be very interesting, as being the largest utilisation of natural forces which has been attempted at any country house up to the present.

Sheffield. The second ordinary general meeting of shareholders of the Sheffield Electric Light and Power Company, Limited, was held last week at the company's offices in Commercial street. A dividend of 5 per cent. per annum was declared free of income tax, and the retiring directors were re-elected. The chairman, Mr. George Franklin, explained that in view of the undoubted growing demand for electric light it had been found necessary to rebuild and enlarge the central station in order to make room for new machinery. The new steam and electrical plant would be of the most modern description, and would probably be at work during the present autumn. The station would have an ultimate generating capacity of 80,000 lamps. Twelve and a half miles of underground conduits had been laid in the streets for the reception of the distributing cables. The prospects of the company were most encouraging, and a new issue of 4,000 ordinary shares would be probably made in the near future.

South London Fares.—In the House of Commons on Monday Mr. Byles asked whether the City and South London Electric Railway Company charged fares exceeding a penny per mile for the distance actually travelled by the passenger; that on these fares exceeding penny per mile no passenger duty had been paid; on what grounds this privilege had been permitted to the City and South London Railway; and on what terms other railways may obtain a participation in this privilege. Sir J. Hibbert said: "The facts are not accurately stated in the question. The company are held liable to pay duty on fares charged at a rate exceeding a penny per mile for the distance actually travelled. It is, however, a matter of great difficulty to determine the extent of the liability, owing to the special method adopted by the company for the payment of fares. An arrangement has been arrived at between the Commissioners of Inland Revenue and the company, under which the Commissioners are satisfied that the liability of the company is fully discharged."

Weston super-Mare.—At a committee meeting of the Weston-super-Mare Board on June 27, Mr. Paris, the representative of the Brush Electrical Engineering Company, Limited, attended and explained the nature of his company's system of lighting, and stated that his company would be prepared to make a plan and prepare an estimate of the cost of the works gratis. On the proposition of Mr. Pethick, seconded by Mr. Beedle, it was resolved "that Mr. Paris be requested to give the Board the best proposal for the purchase of their provisional order for a term of years, having regard to the fact that any condition for the payment of undefined goodwill will not be entertained by the Board, and alternatively by a proposal for the erection of works for the supply of electricity, together with approximate estimate of outlay necessary supposing the Board were to undertake its own works." The clerk was instructed to write to the authorities at Bradford, asking for information on the subject of obtaining money to carry out electrical lighting works.

H.M.S. "Resolution." — The new first class battleship "Resolution," which left the Tyne for Portsmouth last week, is lighted throughout with electricity by an installation of about 700 electric lamps, and is also equipped with four electric search-lights of 25,000 c.p., each of which will be worked by a dynamo under protection. Means are so arranged that the ship when in action can be entirely controlled from either of the two conning towers. The vessel is fitted with twin screw engines, each set having cylinders 40in., 59in., 88in., by 51in. stroke. There are eight single ended boilers, each 15ft. 6in. diameter by 9ft. 6in. long, having in all 32 furnaces, 155lb. working pressure. There are no less than 69 auxiliary engines, including steering engine, electric light engines and dynamos, air-compressing engines, distilling engines, evaporator engines, boat hoisting engines, workshop engines. The "Resolution" is 40ft. longer, 5ft. broader, and has 3,680 tons more displacement than the ill-fated "Victoria." As a flagship she will have a complement of 700 men on board.

Manchester.—The engines, boilers, and dynamos at the Manchester electric lighting station have been running for the past few days, and have been tested with satisfactory results. Arrangements are being made for the formal opening of the works on an early date. Some 50 shops and warehouses in and about Market street have been coupled to the electric mains, and enquiries and applications with regard to the terms of supply are being received daily. The current was turned on in some of the offices of the Town Hall for the first time last week. In the presence of the members of the Gas Committee, the Lord Mayor (Alderman Marshall) switched on the light in the committee-room of the gas

department, and although the arrangement of the lamps at present is only of a temporary character the result was most satisfactory. The Lord Mayor after expressing regret at the absence of Sir John Harwood, chairman of the Electric Lighting Sub Committee, and Councillor Brooks, chairman of the Gas Committee, congratulated the committee on the satisfactory completion of the works so far, and expressed a hope that the supply of the electric light to the public, which it is intended shall begin in the first week in August, would be equally satisfactory.

Moffat.—At a meeting of the Commission last Friday, reports by engineers with respect to the proposal to introduce the electric light into Moffat were considered. Mr. David J. Brown, in moving that the proposal of Messrs. Woodhouse and Rawson, Glasgow, be adopted, utilising water power of the Evan river, two miles from the town, said that the engineers stated if the charge were 8d. per unit for the light sold, they calculated that the Commission would make a profit of £1,600 off the private light yearly. But as the Commission would have to make the light cheaper than gas, if they calculated the charge at 6d. per unit there would be apparently a profit of £958. Even though only the half of the light was sold, the profit would be sufficient to repay the capital expenditure in a few years. Mr. Peter Richardson seconded. Provost Young remarked that in all the engineers' reports received the amount of light and profits were altogether matters of assumption. There was not sufficient exactness of data to warrant the Commissioners in proceeding with any scheme. Until electric lighting was less of an experiment and they had more definite information, he moved that no further action be taken. Bailie Knight seconded, and the amendment, that the matter be adjourned, was carried by a majority of two votes.

St. Pancras.—Mr. Gibb, vestry clerk of St. Pancras, has replied to the pamphlet of Mr. Clements on the electric lighting in that parish. He contends that the original estimate of cost has only been exceeded by 8 per cent., and not doubled, as stated by Mr. Clements. Additional works not at first contemplated have been added, and these of course increase the outlay. The cost of the production of the light is rather less than more than the estimate. The £6,500 stated to be a yearly loss was purely mythical, as well as the probable future loss. Mr. Gibb denies that the consumers were ever told 4¼d. or 4½d. per unit would be charged instead of 6d. It was, he asserted, quite correct to estimate £4,000 profit on the current year, and the estimates for the new installation in King's road were as reliable as those upon which their present installation was authorised, and more complete because they had been tested by local experience not available in 1889. After discussion, it was decided to hold a special meeting to consider together the allegations of Mr. Clements, the replies of Mr. Gibb and Prof. Robinson, and other facts connected with the case. The consideration of the Dusting and Slopping Committee's recommendation, that there should be a combined dust-destroying and electric light station in King's road, was deferred to the same meeting.

Guildford.—At the meeting of the Guildford Local Board last week the town clerk read a notice he had received from the Holloway Electricity Supply Company, 34, Victoria street, Westminster, of their intention to apply on or before November 21 next for a provisional order to supply electricity in the borough. Alderman Mason asked whether, supposing the company got the provisional order, they would have a monopoly of lighting by electricity within the borough. The Town Clerk replied that they would not. Mr. Salsbury did not see how it could be any injury to the town. He did not think they could oppose the application, unless they intended to get a provisional order themselves as a council. Alderman Allen said they had already determined not to do that, and therefore he thought they should be only too pleased if someone came and supplied them with electricity. Mr. Cable said the Council had decided to assist any company, under certain conditions. Alderman Carling thought that all that was necessary was to see that the company was one of proper standing. Mr. Colebrook asked if it were not worth while to see if the Corporation could supply the town with electricity, and not let an outside company come in? The Mayor said that had been before them, and they could not see their way to do it. The matter then dropped, the Town Clerk remarking that the application would come before them again later on.

Leicester Co-operative Society.—A meeting was held of the Leicester Co-operative Society last week to discuss the question of lighting the whole of the central premises of the society by means of electricity. Mr. Neale moved that the committee be empowered to adopt the principle of electric lighting for the central premises. As co-operators and friends of social progress they would but be doing right in taking action in the matter, and it would be bound in a short time to be a paying concern. The society had been of opinion for a long time that they ought to wait, but so far as he could see they had arrived as nearly as possible at perfection with the light. From both a sanitary and financial point of view they ought to take up the matter, which was of great importance to them all. Mr. Yates moved as an amendment that it be deferred for six months. Mr. Newton supported the proposal to introduce electricity, and quoted statistics to prove the financial success of many electric lighting systems in London. A most animated discussion ensued, in the course of which Mr. Bond mentioned that in consequence of the successful results of their efforts in other towns the Midland Railway Company had decided to lay down an installation for a portion of their works at Leicester. Mr. Harrott, the secretary, said the figures he gave at a previous meeting were thoroughly reliable. He believed they could obtain a good installation for £1,000. They wanted a first-class system, and he would be opposed to opening the tendering to competition and adopting the lowest estimate. On a vote being taken, it was decided by 79 votes to 27 to give the committee the necessary authority to proceed with the electric lighting system.

Huddersfield.—In a month or two, says a note in the *Manchester Examiner*, Huddersfield will have a public supply of the electric light available. The works are large enough to contain machinery capable of generating electricity to supply 20,000 lamps, each of 16 c.p., together with reserve plant. There is also ground upon which the building can be enlarged at the northern end. The machinery already put in will provide for 9,000 eight-candle lights; but it has been found necessary to double the capacity of the machinery in order to meet the great and unexpected demand for the supply of electric lighting, and it is hoped that the whole power will be ready for putting in operation by the 31st of October. The electric generating machinery consists of a high-tension alternating current plant having an output of 250 units. Four boilers of the Babcock and Wilcox type have been fixed equal to 800 h.p. in the aggregate, supplying steam to three compound vertical condensing high speed engines, which drive three Mordey alternators, which supply electricity at a pressure of 2,000 volts. The additional productive power referred to above will be provided by one large machine generating 250 units. This plant is supplied by the Brush Electrical Engineering Company. The lighting of the station will be by means of arc and incandescent lamps. The current is to be conveyed from the works along four primary mains run in conduits, which are paper tubes bedded in bitumen, and protected by cast-iron casing. These have been laid by Messrs. Callender and Co., of Leadenhall street, London. The primary mains or cables along which the current is conveyed are of the concentric type and have been supplied by Messrs. Siemens Bros. and Co., Woolwich. The conduits and mains are laid to embrace the chief thoroughfares within a certain area. Seventy-five public bodies, persons, or firms have arranged to take the electric light. The demand is equivalent to about 9,000 8-c.p. lamps, for which provision has already been made, and it is said that a comparison of other towns which have had the start with the new form of lighting, discloses considerable enterprise on the part of the Huddersfield people. The charge made for the supply of electricity will be at the rate of 6d. per Board of Trade unit.

Three-Wire System at Bradford.—The following is Lord Kelvin's report to the Gas and Electricity Committee of Bradford on the proposed extension of their system: "I have duly received the printed reports of Mr. Sydney Baynes and Mr. James Shoolbred and other documents sent to me in accordance with your instructions. I have also had a full discussion of the whole subject in conference with Mr. Baynes and Mr. Shoolbred, and I have since received a chart and some further information from Mr. Baynes. After careful consideration of the whole subject, I now report as follows: (1) In my opinion the best arrangement for improving and augmenting the electricity supply according to the present limited demand of the committee is that recommended by Mr. Baynes and described in his printed report, according to which a third conductor is brought back to the generating station, and all the adjustments to give proper electric pressure to the consumers are performed at that station; (2) the method proposed by Mr. Shoolbred, whether for a three-wire system or a five-wire system, according to which the adjustments of the pressure for the consumers at different parts of the system are entrusted to automatic mechanism at the feeder ends, is not adapted to give in ordinary circumstances the requisite uniformity of pressure to the consumers, and is liable also to serious dangers and objections; (3) I do not think it probable that when the time comes for extensions to greater distances it will be found advisable to adopt the five-wire system, or to go beyond the three-wire system; (4) it seems to me probable that the best and most economical plan for extending to much greater distances than those covered by the system now in use will be by the establishment of a second generating station in some convenient position at a distance of not more than one mile and a half from the present generating station; (5) I have carefully considered the question of 'simple shunt' or 'compound winding' for the balancing motor generator, and although I am informed by Mr. Baynes that compound wound motor generators are now in use at Southampton, and give good results there, I believe that simple shunt winding will be found to give equally good results in ordinary use, and to be safer in respect to contingencies of possible occurrence."

Windsor.—At the last meeting of the Windsor Sanitary Authority, the town clerk read some correspondence from the Board of Trade on the subject of the Windsor and Eton Electric Light Company with respect to the question of the revocation of the order. The Board of Trade point out that the Windsor Company have failed to satisfy the Department that they are in a position fully and efficiently to discharge the duties and obligations imposed upon them by the order, as required by Section 7, and that, in these circumstances, it devolves upon the Board of Trade to consider whether they should not revoke the order. Before, however, taking this course, the Board of Trade hold themselves prepared to receive any observations which the company may desire to offer on the subject. Mr. Sydney Morse on behalf of the Windsor Electric Light Company, had written: "You no doubt are aware of the difficulties there have been for some time past in the money market which have prevented the progress in raising capital for electric lighting schemes. Clients of mine (other than the Windsor Company) are anticipating the issue of a large amount of capital, portions of which will be available for such schemes as that of the Windsor and Eton Company. Though I cannot pledge these clients at the moment to find the required capital for the Windsor Company, they write me that it seems more than probable that in time they will come to the assistance of the Windsor Company if

the position proves locally to be as good as is represented. Meanwhile, the company has erected plant and is supplying current as far as possible in the district, fully anticipating that before very long they will be able to obtain further capital and extend their operations throughout the entire area. Under these circumstances, I trust the Board of Trade will permit the consideration of the question of revocation to stand over for the present." The Town Clerk suggested that the best course to adopt would be to again appoint a committee of all the members of the Council who were not interested in either gas or electricity, to see the electric light company and find out whether the company would be likely soon to be in a better financial position and be able to comply with the Board of Trade requirements. This seemed to be universally approved, and the suggestion was adopted on the proposition of Councillor Cantrell, seconded by Councillor Dyson.

Birmingham.—The question of electric lighting is dealt with by the General Purposes Committee in the report to be presented at the next meeting of the Birmingham City Council. Notice having been received from the Birmingham Electric Supply Company of their intention to apply during the present year to the Board of Trade for a further provisional order, an interview between the special sub committee appointed for the purpose and representatives of the company took place. The intention of the company is to ask for authority to supply electricity in the Edgbaston district and the jewellers' quarter, but with extended areas. The committee had, they state, to consider whether they would permit the existing company to extend their area, or whether they would withhold their consent pending an application for an order by the Corporation themselves. It was felt that consent could not be fairly withheld on any other ground, and that if a Corporation order were applied for, it would probably be necessary, for the successful development of the installation in the hands of the Corporation, that terms should be arranged with the Electric Supply Company for the purchase of their existing undertaking. The reasons generally put forward in favour of the supply of gas and water by corporations do not seem to apply with nearly the same force in the case of electricity. There is no monopoly of supply under the Electric Lighting Act, 1882, as in the case of of gas, nor is the supply of electricity like that of water, an absolute necessity of existence. The disturbance of the streets is very slight, and the practical control of the same is already secured by sufficient clauses, while it can scarcely be expected that there will be any economy in working expenses in the hands of the Corporation. The commercial value of the company's undertaking can hardly be estimated, but it is evident that in Birmingham, at all events, it has to meet a serious competition with a cheaper gas supply. The taking over of the supply of electricity by the Corporation would necessitate a large addition to capital expenditure at the present time, and it is not likely that this expenditure would be highly remunerative. On the whole, the committee recommend that the proposed order of the Electric Supply Company be not opposed, except upon clauses, and that the application and the draft order, when submitted, be referred to the committee, with power to take such action as they may think desirable for protecting the interests of the consumers and the Corporation.

Aberdeen.—The state of electric lighting in Aberdeen is thus summarised by the *Scotsman*: "Following the example of the municipal authorities in a large number of towns in England and Scotland, the Town Council of Aberdeen applied to Parliament for an Electric Lighting Act, and are now busily engaged in carrying out its provisions. The compulsory schedule of streets—that is, those thoroughfares which it was necessary under the Act to light within two years of the passing—were few in number, and lay entirely in the centre of the business part of the city. Acting under the advice of their engineer, Prof. Kennedy, the Town Council decided to extend the area in which current will be first supplied over what is practically the whole of the business portion, and nearly as far west as the end of Union street. Distributing mains will accordingly be laid along Castle street, Union street to Bon Accord street, Union terrace, Rosemount viaduct, Schoolhill, George street, Upper Kirkgate, Broad street, and Market street. It is proposed latter on, if the demand for light should increase as fast as it has done in other cities where light is now to be supplied, to extend the lighting area to the very west end of the city, and so cover a large residential district there, a district which is to Aberdeen what the west end terraces are to Edinburgh. As showing the increasing demand for the illuminant in Glasgow, for example, the original order was for 12,000 lamps lighted at one time of 8 c.p., which would mean about 18,000 lamps actually connected, and already, although the station has only been running about a couple of months, applications have been received, we understand, to connect more than 27,000 lamps, and the applications are constantly coming in, so that the Corporation have had to extend their plant. Aberdeen is one of those cities in which the gas is under the control of the Town Council, and the gasworks lie at the east end of the town, about half a mile beyond Castle street. It happened very fortunately, seeing that the management of the electric lighting and of the gas will be so nearly connected that an excellent site for a central station was found to be available upon a plot of land adjoining the gasworks. In these circumstances, the gas coke, which it is proposed to use for fuel at the station, can be delivered direct into the fuel bunkers from the existing lines of rails within the works themselves. The central station, so situated, is now in process of erection, the walls being already 14ft. or 15ft. above the ground. The total cost, exclusive of land, but including buildings, was estimated by the engineer to be £24,400; but the actual cost, now that the tenders have been received, has been found to work out very considerably less than this figure. There is good hope that the work will be completed by the end of the year. It is proposed to charge 7d. per Board of Trade unit for the current."

The Roundhay Electric Trams.—The following letter from Mr. W. S. Graff Baker appeared in the *Leeds Mercury* of the 17th inst., with reference to the Roundhay electric trams: "My attention has been called to a second communication on the subject of the stoppage of electric cars, signed by 'A Frequent Passenger,' which has appeared in the columns of your paper. This communication is scarcely worthy of attention, but as it is possible that many people in Leeds do not clearly understand the position of the electric tramway *vis a vis* the Corporation, it may be well to take this opportunity to explain. The installation on Roundhay-road was put in for the purpose of showing to the Corporation and the people of Leeds the practical possibilities of electric traction, with a view, in the event of the impression being favourable, to extend the system throughout the borough. The present electric lines, running as they do from well outside the centre of the city to a pleasure resort, have never paid; but, on the contrary, have caused a serious monetary loss to myself since the lines were opened. This, too, notwithstanding the fact that the cost of operation is lower than that of any other tramway in the United Kingdom. But it is easy for anyone to understand that even if the total cost of operation were only 1d. a mile, if the receipts were only ½d. a mile a loss would ensue. For this demonstrative line, only sufficient plant was put in to operate it as a demonstration instead of as a commercial undertaking; and the time that it was at first thought would be necessary for the purpose of such demonstration (and to enable the Corporation to get control of the remainder of the tramways in the city) was estimated at one year. Owing to delays, which it is useless to go into at present, and of which you are well aware, the line has now been running nearly two years, and it is almost impossible, at the present time, to state when the lines will either be extended or removed. This explanation should answer the question as to why a duplicate plant has not been put down for Roundhay road. As regards the cost of operating with a reserve plant, this would not be any higher but probably lower than the cost of working with a single set of machinery. As most intelligent people are aware that the production of mechanical power on a larger scale is more economical than on a smaller, should the line be extended to twice its present length with a reserve plant, the cost would remain the same, or would be lower. It was with regret that the lines were stopped, as we always endeavour to grant every convenience to our customers; but compulsory examination of the machinery on the part of the insurers etc., have caused us, much against our will, to stop for the short time necessary to enable such inspection to be made."

Dublin Southern Tramways Parliamentary Enquiry.—The first tramway case to which the model clauses were applied was that of the Dublin Southern District Tramways Bill, which came last Friday before the Select Committee of the House of Commons, over which Mr. Samuel Hoare presided. The object of the Bill is to authorise the use of mechanical power in the working of the Dublin Southern District Tramways, and to enable the company to acquire the undertaking of the Blackrock and Kingstown Tramways Company. Mr. Cripps, Q.C., and Mr. J. D. Fitzgerald appeared for the promoters, and Mr. Pembroke Stephens, Q.C., and Mr. Clifford for the petitioners against the Bill—the Dublin, Wicklow, and Wexford Railway Company. Mr. Cripps, in opening the case for the promoters, said the point in dispute between the promoters and their opponents was a very narrow one. Really the only point was what form of protective clause should be inserted in the Bill in order to ensure that no damage should be done to the railway company's railway signals by the use of electrical power along the tramway lines. One of the purposes of the Bill was to have a thorough service in the hands of one company, and with one gauge from Dalkey to Dublin. He understood that the petitioners desired to say to that committee that the tramway company should not be allowed to use electrical power at all. If they were allowed to use it they should do so under certain restrictions. This question of protective clauses had been considered by the Joint Committee on Electrical Powers after an enquiry which lasted for a large number of days. It was shown before that committee that electrical power was both the best system from a public point of view, and, what was more important, was the cheapest. The joint committee had prepared a model clause, and he believed their report had been laid upon the table. Whether that clause was favourable to the tramway company or the railway company, the promoters of the Bill would be prepared to accept that model clause. At this point a proof of the report of the joint committee was produced and Mr. Cripps read the model clause, which stated the undertakers should, in using the electric powers of this Act, employ insulated returns or uninsulated metallic returns of low resistance. The great question before the joint committee was whether the earth return should be direct or accidental, and this clause seemed to be a compromise. Then the clause stated that the undertakers should be subject to certain regulations in the schedule, and that they should take all reasonable and proper precautions. Then there was a penalty clause. There was a proviso that this clause did not apply to electric lighting purposes. He undertook in the fullest possible way to insert that model clause. He would ask the committee under these circumstances not to ask them to call expert witnesses at enormous cost and to go over the case again. Mr. Pembroke Stephens said there were other points at issue besides that of the protective clauses. The petitioners urged that the erection and maintenance of poles and wires for the carrying of electrical currents along the tramway would be injurious to the petitioners. They also urged that powers to work the tramways

by mechanical or electrical power was in contravention of the express provisions in the Acts authorising this tramway, the Act only being passed by Parliament under the provision that the tramway should be worked by horse power. They further submitted that it would be in contravention to the order in council of the Lord Lieutenant, and that the working of this tramway by electricity could not fail to inflict injury on the petitioners. This tramway ran absolutely parallel with the railway, almost touching at some points, and at one point, at all events, actually crossing the railway. He accepted the model clause as far as it went, but the main point was whether this company should have electrical power or not. Mr. Cripps said he would call evidence on that point. Mr. Spagnoletti, C.E., was first called, and said he had examined the route of this tramway. He was of opinion that if proper protective clauses were inserted in the Bill, there was no objection to the use of electricity on this tramway from a railway point of view. Electrical power on tramways was both convenient and cheap. Cross-examined, witness admitted that everything should be done to protect the railway signals. Mr. A. Siemens, who said he had a large experience of electric traction in various parts of the world, said there was not the smallest reason why the electrical system should not be used in this case. It was a very simple case. Cross-examined, witness said the railway would be protected by the Board of Trade, and the Board of Trade could not allow a system that was likely to interfere with anything else. There was no danger if there was proper workmanship. In answer to the chairman, witness gave an instance of a continental tramway worked electrically crossing a railway on the level. Mr. Pembroke Stephens urged that if the committee were going to pass the Bill, at least they should ensure that there should be a proper local enquiry and safeguard before anything was done, so as to prevent any mischief happening. Mr. W. L. Payne, general manager of the Dublin, Wicklow, and Wexford Railway Company, was then called. He said the wires by which the signals were worked would be parallel with and very close to the proposed overhead wires for the tramway. The tramway crossed the railway. They were in an exceptional position in Ireland in reference to the main block signal stations. The staff are under the witness's control, but the maintenance was taken charge of by the Post Office. He considered that the model clause did not in this case give the railway company sufficient protection. He thought that the proper maintenance of the tramway company's electrical system would depend to a great extent upon its financial position, and if that did not become better than it was at present, it would be a very bad look out. He thought it a great hardship that the railway company should not have an opportunity of being heard before the Board of Trade before the use of electricity was sanctioned upon this tramway. Cross-examined, witness said the block system on the Dublin, Wicklow, and Wexford Railway was the best in the country. Mr. Langdon, C.E., superintendent of the electrical department of the Midland Railway, gave scientific evidence with regard to electric traction, and said if they had a tramway worked by the electrical system they must have proper protection. Mr. Cripps agreed. Mr. Harrison, general manager of the London and North Western Railway Company, was next called, and said if he was responsible for the conduct of the Dublin Railway Company, he should view the introduction of this electric tramway with the very greatest apprehension. If there was the slightest possibility of the smallest interruption with railway signals it would be a very serious matter. Mr. Cripps replied on behalf of the promoters. Mr. Clay, solicitor to the promoters, was then called to give formal proof of the uncontested portion of the preamble. After consultation with his colleagues, the chairman announced that the committee had decided that the preamble was proved, and they understood that model clauses would be put in the Bill. The proceedings were then adjourned, in order that the Bill might be brought up in its final form.

PROVISIONAL PATENTS, 1893.

JULY 10.

13353. **A new or improved means of automatically regulating the brushes of dynamo-electric machines.** Herbert Oswald Boden, 1, Walmer-place, Old Trafford, Manchester.

JULY 11.

13408. **Improvements in electric batteries.** James Henry Mason and Alfred Van Derwerken, 52, Chancery-lane, London. (Complete specification.)

13412. **Improvements in automatic regulators for electric generators.** Eugen Conrady, 56, Low-street, Keighley.

13448. **Improvements connected with or relating to motors or instruments for measuring electricity.** Felix Heinrich Aschner, 6, Lord-street, Liverpool. (Complete specification.)

13469. **Improvements in electric railway signals.** Frank Boulton Aspinall, 24, Southampton-buildings, Chancery-lane, London.

13490. **An improved electric bell.** Berthold Zetschel, 40, Chancery-lane, London. (Complete specification.)

JULY 12.

13507. **Improvements in range-finders, and in electrical appliances for transmitting the indications of the same to a distance.** Archibald Barr and William Stroud, 154, St. Vincent-street, Glasgow.

13533. **Safety insulated clip for extracting and replacing electric fuses.** Clarence D'Oyley Hutchins, Holly-grove, Feltham Hill, Middlesex.

13551. **The production of aromatic amido compounds by means of electrolysis.** Henry Edward Newton, 6, Bream's-buildings, Chancery-lane, London. (The Farbenfabriken vormals Friedrich Bayer and Co., Germany.)

13552. **Improvements in electric arc lamps.** Alfred David Lewis and Frank Michael Lewis, 6, Bream's-buildings, Chancery-lane, London.

13568. **An improved dry electrolytical process for the production of an alloy of lead and sodium or potassium.** Claude Theodore James Vautin, 1, Queen Victoria-street, London.

JULY 13.

13610. **Improvements in dynamo-electric machines.** Alphonse Isidore Gravier, 191, Fleet-street, London.

13633. **An improved electric clock.** Herman Wubbeler, 55, Chancery-lane, London.

13644. **Improvements in or relating to telegraphic type printing apparatus.** Eugene Magnin, 18, Buckingham-street, Strand, London.

13647. **Improvements relating to galvanometers.** Carl Ludwig Rudolph Ernest Menges, 45, Southampton-buildings, Chancery-lane, London.

JULY 14.

13672. **Improvements in apparatus for transmitting telegraphic indicating, and other analogous signals or movements by means of electric currents.** Andrew Betts Brown and William Falconer King, 154, St. Vincent-street, Glasgow.

13723. **Apparatus for the electrolytic production of bleaching liquid.** Carl Kellner, 46, Lincoln's-inn-fields, London.

JULY 15.

13730. **Improvements in connecting to zinc rods of Leclanche or other galvanic batteries.** Groggon and Co., Limited, 16, Upper Thames-street, London.

13749. **Improved means of working and controlling electric elevators.** Michael Holroyd Smith, 161, Trinity-road, Upper Tooting, London.

13773. **Improvements in arc lamps.** Sidney Alfred Hunter, 23, Southampton-buildings, Chancery-lane, London.

13774. **A means of maintaining the human body in electrical connection with the earth.** Eldridge Spratt, 11, Hinde-street, Manchester-square, London. (Complete specification.)

13779. **Improvements in telephone circuits.** Jorgen Jacobsen Møller, 22, Southampton-buildings, Chancery-lane, London.

13792. **Fluid operated electric switches.** Jean Joseph Paul Clariot, 53, Chancery-lane, London.

NOTES.

Black Forest.—Electric transmission of power has been utilised for the cotton mill at St. Blaise, in the Black Forest.

Electrotechnology.—A manual of electrotechnology in German has recently been issued by C. Grawinkel and K. Strecker.

Genoa.—The capacity of the plant to be installed for the public lighting of Genoa will be 800 arcs. The mains will be underground.

Milan Tramway.—The inauguration of accumulator electric cars on the tramway from Milan to Monza took place on the 20th inst.

Barium Accumulator. — An accumulator whose active material is composed of peroxide of barium is used by H. Lehmann, a German electrical engineer. The liquid is a solution of barium in water.

Theatre-Lighting at Verdun.—The new theatre at Verdun is lighted throughout with electric light in two distinct currents, one fed by current direct from the mains and the other from accumulators, so that in no likely case will there be complete extinction.

Blackening of Lamps.—Elihu Thomson thinks that lamps cannot be made which will not blacken and deteriorate, if carbon be adhered to as material; "and carbon as yet seems to be the best material in existence -it is so on account of its infusibility and its apparent volatility."

Long-Distance Telephones.—It is not only to the telegraph that long-distance telephones will be rivals. The railway companies also in America, it is said, feel the effect, as many directors of companies and others who used to travel now use the telephone to talk over affairs on Board days.

Electric Fishing Boat.—The fishing boat "Matador,' owned by Mr. Schellbap, says a Sheffield paper, has just arrived at Grimsby from Bremen. This boat is moved entirely by electricity, and is a new departure altogether in the fishing trade. The vessel is now lying in the Grimsby Fish Dock, and is attracting considerable attention.

Fatal Accident.—We regret to learn of the death by drowning on Tuesday at Hampton-on-Thames of Mr. W. C. Palmer, aged 23, an electrical engineer, who was employed on the staff of the General Electric Power and Traction Company. Mr. Palmer has only recently joined this company, and his untimely death is extremely regretted by all, especially those associated with him in his profession.

Mechanical Engineers.—Among the papers to be read at the forthcoming annual meeting of the Institution of Mechanical Engineers, to be held at Middlesbrough next month, are the following: "Description of Electric Rock-drilling Machinery at the Carlin How Ironstone Mines in Cleveland," by Mr. A. L. Stevenson, of Durham; and "On the Artificial Lighting of Workshops," by Mr. Benjamin A. Dobson, of Bolton.

Lisbon.—The gas company at Lisbon has lost some of its largest customers, who have set up their own electric lighting installations. The spinning mills of Desgenatais, Westhalen-Lemaitre, and Lemaitre Bros. have been fitted up by M. See, of Lille, and the other great firm of Fouquet-Lemaitre has had electric light since 1890. This installation was supplied by Sautter-Harlé. English firms do not seem to be able to secure many installations in the district.

Electrical Indexing.—A handsome number is to hand of the technical magazine *Electrical Engineering* (565, The Rookery, Chicago), giving some well printed views of the exhibition, accompanied by a guide to the exhibits, by the editor, Mr. De Land. But the most useful feature of this journal is the extended and careful index to electrical literature, with short summaries of the interesting general articles, which no doubt proves very valuable as a "review of reviews."

Exhibition at Porto Rico.—The Science and Art Department have received through the Foreign Office particulars of an exhibition to be held in November next to commemorate the four hundredth anniversary of the discovery of Porto Rico. Exhibitors are invited to send objects that are or may become articles of commerce. Exhibits will be admitted free of duty, and no charge will be made for space. Application must be made by September 1st.

Telephones on Railways.—A paper was recently read by G. Dumont and E. Bernheim before the Académie des Sciences on the use of telephones on railways. M. Dumont pointed out that it has been only during the last year or two that telephones have been used on railways, and he investigates the conditions of their application, what uses are made of the telephone, and what might be done. M. Bernheim described the various systems of telephones utilised, and the advantages of particular forms of instruments.

Lighting of Estuaries and Rivers.—Dealing with this subject before the Maritime Congress, Mr. W. T. Douglas, consulting engineer to the Trinity House, said, with regard to electricity for this purpose, that in the form of incandescent lamps it was a source of illumination which had many advantages where the central station was not too far distant from the beacon lights, and more particularly where the central station was in the hands of port authorities. In New York Harbour the electric light was employed to define Gedney's Channel; there 100-c.p. incandescent lamps, with three loops in the filament, were attached to spar buoys placed 1,000ft. apart.

Light Diffusers.—M. Raffard, writing to the Société de Physiqué with reference to the recent proposal for making glass for arc lanterns corrugated on both sides, mentions that in 1879 Breguet supplied 30 large lamps for the Havre harbour works. At first the lantern glass was painted white, but as this obscured the light too much, he had the idea of replacing the glass by two sheets of the ordinary corrugated glass of commerce placed with the corrugations at right angles. This had the desired effect; the lantern became luminous over its whole surface, and the deep shadows were softened. The only objection is that the ground and object present a slightly mottled appearance, but this inconvenience was of no importance with the heavy work done in the shops.

Boiler Efficiency.—Tests have been made in Sheffield with Oates's automatic register as applied to steam boilers, so as to raise the efficiency without smoke. Three trials have been made—two at the works of Charles Cammell and Co., Limited, and one at Messrs. Walker and Hall's works. The tests made, it is said, showed conclusively that smoke can, in the case of steam boilers, be prevented by various appliances, and with considerable economy in the consumption of fuel. Mr. B. M. Fletcher, of Westminster, who conducted the tests, states as regards the first two trials that the appliance tested being of simple construction and automatic, showed itself to be a successful means of raising boiler efficiency without smoke, and that it can be used by a comparatively careless and ignorant stoker.

Combined Arc Lamp and Post.—A novel kind of arc lamp has been constructed by Rudolph Hunter, of Philadelphia, for the General Electric Company. The

object is to reduce the weight of the lamp to the least possible amount, so as to allow the use of a light and graceful pole. This is accomplished by putting all the heavy regulating mechanism of the lamp inside the top of the pole and not in the lamp proper at all. The lamp is connected to the regulating gear by a fine wire, and itself contains nothing but the carbon-holders and means to feed the carbons. The projecting arm which carries the lamp is jointed, and can be lowered for cleaning and refiling the lamp. This lamp is illustrated in the *Electrical World* (July 8), where it is stated that the combined post and lamp has been exhibited in Philadelphia with entire success. The pole is of hollow metal; the whole is of very light construction, and is meant to supersede the ungainly structures now so often met with in street-lighting by arc lamps.

A Royal Societies' Club.—Under the title of the Royal Societies' Club, a club is being formed which will have for its chief aim the bringing together of members of the Royal and learned societies under the usual conditions of club life, affording opportunities of social *réunion* for the class of members to which the new club will specially appeal. The membership is to be limited exclusively to presidents, members of council, fellows and members of the principal Royal and learned societies of the United Kingdom, India, and the Colonies, academicians and associates of the Royal Academies, together with the presidents, members of convocation, and professors of the universities and various Royal institutions. Premises comprising the whole of the block 63, St. James's-street have been secured for the club-house, which, it is expected, will be ready for occupation early in October. A special feature of the club will be an extensive lecture-room available for the use of the societies embraced in the constitution of the club, or members thereof, for holding meetings. The temporary offices are 8, Waterloo-place, Pall-mall, S.W.

Goebel Lamps.—The Goebel lamp case is proceeding merrily in the Milwaukee Courts with all the concomitants of the stiffest legal fights. Affidavits of the strongest kind abound—those on Goebel's side alone now numbers upwards of 250; accusations of absolute misrepresentation, fraud, bribery, and perjury are common incidents. The Columbia Company have issued a splendid portrait of the old man, meant to produce a favourable impression. Mr. Clarence Seward alleges that the glass tubing out of which the famous Goebel lamps were made was purchased on September 28, 1892; that lamp No. 4 was made by Aug. Hyer at 468, Grand-street, New York; that Goebel only showed oil lamps on his telescope; and that most of the affidavits were signed without knowledge of the contents. Max Hoffmann, a saloon-keeper, testified that Goebel, junior, had said: "That is a nice kind of a judge; if he had dropped on Nos. 1, 2, and 3, instead of 4, he would be nearer hitting the nail on the head. I made those lamps." On Goebel's side, Mr. J. E. Brill testified he had seen the lamps or others like them in Goebel's shop in 1890. Henry Goebel, jun., testified that Max Hoffmann had tried to bribe him to go on the other side for 20,000dol., and go out of the country with a permanent position in the company; that he had led Hoffmann on, to see what he would say, and then went immediately to relate the conversation to Mr. Kenyon, the counsel. The judge's decision in this interesting case was expected by the 17th inst., but we have not yet had particulars.

A Loud Telephone.—A loud-speaking telephone has been devised by Mr. Graham, of the Electric Wiring and Fittings Company, 2, Princes-street, Westminster. In this case, the usual induction coil has been discarded, and the two instruments, transmitter and receiver, are directly connected in circuit with the line and the battery. The transmitter of A at one end of the line is connected to the receiver of B at the other end. As this arrangement only permits of A speaking to B, and not of B replying to A without a change of the connections and a substitution of apparatus, two separate lines are employed having a common return wire. On the second line the transmitter of B is directly connected to the receiver of A. The two correspondents can thus talk quite freely with each other, and as the receivers speak out so as to be heard in any part of a room conversation can be carried on by each person simply speaking to his transmitter. This apparatus is attached to flexible conductors and is held in the hand. To open a conversation it is sufficient to pick up the portable transmitter and press a button in its casing so as to establish the circuit, then speak into it. The receiver at the other end acts as its own call-bell by the loudness of its voice, and the response comes equally prompt and loud. The user has, therefore, no need to listen carefully with one or two receivers held up to his head. All he has to do is speak into his transmitter and keep his ears open. The apparatus is chiefly intended for domestic service from one part to another of a house, office, or workshop.

Storage Battery Tests.—An exhaustive and elaborate report by Profs. John W. Langley and Chas. T. Mabery is published on the Ford-Washburn storage cell, in which its electrical, chemical, and mechanical properties are thoroughly considered. As a result of the test the following conclusions are given: (1) The cells have not appreciably changed their internal resistance during two months' constant use, when tested under similar conditions. (2) Vibration and shaking, continued for an aggregate of 422 hours, did not increase the internal resistance. (3) The ampere capacity of the cells is 150 hours when tested to exhaustion, and when drawn down to one volt a cell holds 133 ampere hours at a 10-ampere rate of discharge. (4) The practical working limits of voltage are from two volts to one volt. (5) The cells do not show any marked tendency to sulphating, and their internal resistance is not permanently raised thereby. (6) During the interval covered by this report neither large rates of charging and discharging nor a prolonged course of vibration, imitating that of a street car, produces any measurable deterioration of plates. In this respect the Ford-Washburn cell was in marked contrast to a cell of the grid type used for comparison. (7) The ampere efficiency varied from 73 to 86 per cent., and the energy efficiency from 55 to 72 per cent. (8) The electrical and mechanical hard treatment to which the cells were subjected in their handling was excessive, and indicates that they have the qualities to withstand rough usage in practice. No measurable impairment of them was developed by exceptionally severe electrical and mechanical usage during two months.

Electro-optics.—M. Basset has published in *La Nature* an interesting review of the situation of the present knowledge of electro-optics. The author describes the action of the electromagnetic field upon light as one of the most attractive branches of optics. He divides the discoveries made up to the present into four groups: (1) The experiments of Faraday, showing that when a beam of polarised light is transmitted across a magnetised medium space, a rotation of the plane of polarisation is produced; (2) the experiments of Kerr, showing that the action of electrostatic force on a transparent medium consists in converting it into a medium optically equivalent to a crystal with single axis, this axis being in the direction of the face; (3) experiments of Kerr on the reflection of polarised light on the surface of a reflector of magnetised iron, show-

ing that a rotation of the plane of polarisation of the light reflected is produced, this rotation being in certain cases in the same direction, and in others in the opposite direction of the amperian current, which may be conceived as producing the magnetic force; (4) experiments of Kundt on the reflection of light by iron, cobalt, or nickel when magnetised, and also on the transmission of light through thin magnetised slices of this metal. Although Hall's effect seems to be intimately connected to the action of a magnetic field or light, this connection is not yet established beyond contradiction. After having discussed the conclusions which may be drawn from Kerr's experiments on the effect of electrostatic force, M. Basset indicates the following experiments as being yet required: (1) Experiments on the reflection of light by a transparent magnetised medium — such as glass, perchloride iron, and also, if possible, liquid oxygen; (2) experiments on reflection by magnetised metals and on the transmission of light through these metals, special attention being given to the effects produced by the non-luminous parts of the spectrum; (3) experiments on reflection by electrified metallic reflectors.

Ship Electric Lights.—In the course of a paper on "Ship Lights and Collisions," read last week before the Maritime Congress, Mr. J. Kenward pointed out the disabilities attending the use of many white masthead and anchor lights and coloured lights of similar construction. He said that he had always advocated the common increase in power of all the lights, and the use of an illuminant in the coloured side-lights as would nullify the reduction of power through colour, and so render the emerging beams of all the lights approximately equal in intensity. In this way the three lights of a moving steam vessel, or the two lights of a moving sailing vessel, may be seen at the maximum distance possible to their position and elevation, and may afford an unmistakable signal of the course the vessel is keeping. He said that electricity was the only convenient means to effect this, and he had arranged some years ago an incandescent lamp of about 100 c.p. for the red light, and another of about 200 c.p. for the green light, together with, for the latter, a particular tint of green glass, which had since been adopted as a standard by the Board of Trade. In this condition, the side-light beams were equal in intensity with the masthead beam. The "Roslin Castle," of the Castle Line of Sir Donald Currie, was the first to adopt this plan of equal lights. It had been quite successful there, though the earlier forms of the apparatus had been much improved since 1884, when he first publicly urged the plan. There was at present an abundance of electric lighting on board the finest ships, and in the case of a few it had been applied to the side lights, but not for the most part in the best manner, or with any reference to equality of beam. There was no longer any official objection to electric side lights, and it might be confidently predicted that in a few years electricity would displace every other illuminant for ship lights, and even for land lights, because its surpassing power could be combined with a largely reduced size of apparatus, and with a striking economy of cost per unit of light.

Blackening of Lamps.—We mentioned the other week Prof. Elihu Thomson's ideas on the volatilisation of carbons. Further details of his views, from a paper on "The Life of Incandescent Lamps," will be interesting. He says that carbon is as yet the best material for that purpose known, and is so from its infusibility and volatility. It actually does soften at extremely high temperatures, and will bend readily when so softened. It does not melt at the highest known temperature, but it readily vapourises in the arc lamp. It is very probable that carbon, infusible as it seems, could be fused at arc temperatures while under pressure. Thus, an electric arc in an inert gas at high pressure would probably drip melted carbon, which would form graphite in masses or crystals. The deterioration of incandescent lamps has often been laid to the bombardment of gas molecules, but Prof. Thomson has long been convinced that in a well-exhausted lamp it is due almost entirely to evaporation by high temperature. Just as ice evaporates in vacuo, so carbon acquires in vacuo a certain volatility at an increasing rate of the temperature. He assumes that the vacuum is so good that none of the visible discharge of current takes place, which of course wears the filament by actual carriage of carbon. He thinks that it would be very strange if carbon maintained at so high a temperature in a vacuum did not evaporate at all, as it is well known that almost all substances raised to a sufficiently high temperature do give off insensible vapours, and that melted metals frequently behave as mercury does at the ordinary temperature; the presence of foreign substances and gases will in some instances accelerate the action and in others retard it. A certain evaporation takes place independent of the size of the bulb, from which it follows that the age-coating will be less as the size of bulb increases, as the deposit will be thinner over a large surface. If two lamps were made, one with the smallest possible bulb, and the other with a large bulb, the former would be opaque when the latter would be only slightly darkened. Great stress is laid on the uniformity of the filament. It appears true, he says, that the limit of practical improvement in the efficiency of incandescent lamps is found in the properties of the element carbon, and particularly its volatility. No other less volatile substance has yet been found, and carbon as pure and perfect in structure as possible is likely to hold its place, at least for some time to come, as the material for incandescent lamps.

Electric Beacons.—A paper by M. D. Lo. Galto, of Naples, was presented last week before the fourth section of the Maritime Congress, dealing with harbour lights, light buoys, and beacons in Italy. As far as electric beacons were concerned, the author said that enquiries into the subject had recently been made at Naples. It was found that with the exception of the light installed in 1884 on the Las Puercas reef in the Bay of Cadiz, no similar lights were at present in use in Europe. In this case the illuminating power is supplied by two six-cell Daniell batteries, and the incandescent lamp is only of 1 c.p. — *i.e.*, 4 volts × 1 ampere = 4 watts. The author said that the disadvantages of this beacon were the very low intensity of the lamp and the employment of a clockwork apparatus working for a considerable time. It was, of course, true that the optical apparatus might develop a high coefficient, but in any case the intensity of this small light on the horizontal plane could never be very conspicuous; and although under the special circumstances, where it requires to be seen only from a short distance, it might be sufficiently suitable, it is too feeble a light for ordinary purposes. With regard to the clockwork mechanism, this might certainly work with regularity for some time, but it could not, with the most perfect workmanship and careful maintenance, be looked upon as really reliable, and any interruption of the action in the Las Puercas beacon would at once cause the light to be extinguished. The Harbour Works Department at Naples had been desirous of studying a 3 c.p. lamp, and they made some experiments with a sixth-order light on the head of the San Vincenzo pier, so as to test the optical result. This was sufficiently satisfactory to make it probable that the combination of a sixth-order lantern with a Swan lamp of 12 volts and one ampere would in many cases

be a sufficiently effective danger signal; but this optical result was deprived of much of its importance by the question of renewals of the batteries. The author concluded that for the present the electric lighting of beacons with self-contained generators of the energy required possessed no special advantages; and that since such excellent results were attained by Pintsch's light, the electric light might be set aside so far as these objects are concerned. In some cases electric lighting might be practicable by conveying the current by cable from the shore; but the system would, according to the author, be very costly, and would involve greater precautions in protection of each end of the cable than might be justified by the object.

Commercial Production of Ozone.—The value of ozone as a deodoriser and disinfectant is well known, and it is conceded by all who are familiar with its character that it is capable of rendering many valuable services, not only for therapeutic or sanitary purposes, but in chemistry and in several industrial processes. The difficulty, however, has hitherto been the economical production of this valuable agent on a commercial scale. The subject has for many years past formed the study of most of the leading chemists of this and other countries. Bunsen years ago pointed out that there were hundreds of uses for ozone if only it could be made in large quantities at a low price, while Faraday, in 1851, in a lecture before the Royal Society, pointed out a number of useful results attending its use, and affirmed it to be a most ready and powerful oxidiser. The late Dr. Werner Siemens appears to have been the first, in 1857, to construct an electrical ozonising tube, and he has been followed by Von Babo, Beanes, Ladd, and many others. The practical results, however, appear to have been but limited, and the only outcome, so far as we are aware, is the production of small quantities of ozone in closed tubes, and its limited use in some of the hospitals on the Continent. Among others who have long and closely followed up this question is M. Emile Andreoli, whose researches have led to the perfecting by him of a system of producing ozone on a practically commercial scale with, it is stated, marked economy. In this process, which is in operation at Messrs. Allen and Hanbury's works at Bethnal Green, metallic open ozonisers are used, in contradistinction to the closed and delicately constructed glass apparatus hitherto employed. An alternating current is produced by a dynamo, and is conducted to a transformer which converts it from the ordinary pressure of, say, 100 volts to 8,000 or 10,000 volts. This high-tension current is conducted to metallic electrodes, which are constructed with thousands of points, and a condenser charge is obtained by means of which the oxygen around the points is condensed or ozonised. M. Andreoli found, says the *Times*, that ozone was generated in far larger quantities by means of point-bearing electrodes than when the electrodes are flat surfaces on which the tension is weak and uniform. The electric tension is at its maximum when there are sharp points from which the discharge escapes, so to speak, in a continuous flow. In one form of ozoniser he uses a series of metallic tapes of small section—each edge of which is serrated like a saw, the tapes being strung, gridiron fashion, in a frame. The points give a much higher percentage of oxygen ozonised, a full 5 per cent. of the oxygen of the air being ozonised, it is stated, at the ordinary temperature, and under ordinary conditions by M. Andreoli's apparatus. Other forms of ozonisers are employed for particular purposes.

Electricity in Gas-Pipes.—The piercing of gas-pipes at Paris electrically has given rise to much heart-searching on the part of both electrical and gas companies. An accident which occurred on March 2, 1891, in the restaurant Larue was a clear instance of short circuit—a kind of case that does not occur frequently. High-tension mains were led into a service box at 2,500 and 1,800 volts—the first for public lighting and the latter for charging accumulators—low tension mains at 110 volts for private lighting also were jointed at the box, and one of these touched a gas-pipe. The workmen, instead of advising the gas company, had built the gas pipe into the brickwork, and by some means a short circuit had occurred, piercing some crater-like holes in the pipe, and an explosion occurred. It did not seem that there was actually contact; a little water intervening affording the necessary resistant path to give off sufficient heat to melt the lead. The accident in the rue Notre Dame de Lorette (June 5, 1892) was apparently due to electrolysis. Two box covers were blown into the air, knocking a woman over. They were replaced, but twice after were blown up again the same evening. The explanation given is as follows: The subsoil in Paris is calcareous or sulphated broken material. When a leakage of electricity occurs, the current returns by the gas-pipes, passing through the surrounding soil, forming to this extent an electrolytic bath—cable and gas pipe being the two electrodes, and the soil, impregnated with water often slightly acid, being the electrolyte. Experience shows this to be the case. When a leakage is sought, its presence is accompanied by heating of the surrounding soil, the gas-pipe is electrified, and in the surrounding calcareous soil the lead of the pipes is covered with a powdery layer of carbonate and hydro-carbonate of lead mixed with oxide of lead. This formation of carbonate and oxide causes thinning of the pipe and eventual perforation. The Edison Company since the accident at the corner of the rue Bréda have replaced their conduits of glazed earthenware by cement conduits on the Clerc system, which, it is stated, are more gas-proof; all which goes to prove that special precautions must be taken for the prevention of accidents of this nature. The commission instituted by the decrees of 1884 and 1885 had prepared rules for laying mains, but had made no mention of gas-piping, save to say it was not to be used as a return for electric mains. After the Larue explosion a new commission was instituted which drew up regulations dealing with the following points: (1) Kind of insulation for cables in metallic coverings; (2) insulation of said cables as regards other mains—gas, water, compressed air, etc.; (3) absolute prohibition of inclusion in any manhole for electric mains the pipes of any other service; (4) the arrangement of pipes and conductors in these manholes; (5) obligation to notify the other companies when coming across their mains; (6) obligation to thoroughly test every detail of the electric network at least once a year. The recommendations of the commission are embodied in carefully drawn up regulations carried out under the control of the municipal service engineers. The companies interested are heartily co-operating to prevent the recurrence of accidents.

A New Boiler-Flue Cover.—The usual practice with boilers of the Lancashire and Cornish horizontal type of covering in the side and end flues with curved flue covers, and surmounting them with several inches, say, 9in. to 18in., of brickwork, is not a very economical or advantageous method in the long run. For instance, when it is desired to inspect the boiler or clean the flues, it is found to be an expensive matter to remove the covering over the tops of the flues, and the consequence is that it is rarely removed and replaced. The results of this are that the operations of cleaning and inspection have to be conducted in the dark,

the flues do not get properly cool, and there is loss of time in allowing them to cool sufficiently to permit a man to enter them, whilst at the same time the working water-line outside the plates cannot be examined without taking off the brickwork. Besides these there are other disadvantages, one being the great expense necessary in case of a thorough examination of the boiler being required. Mr. G. C. Taylor, of Helsby, near Warrington, has, however, devised a flue cover and composition which overcome these difficulties. The arrangement consists in building up the brickwork straight up to where the flue cover is to rest, and right round the back and side of the side and back flues. As the thickness of the flue cover and composition is only about 4in., or more if necessary, the flue can generally be raised up 6in. higher and still be under the water-line with safety. This method therefore gives one square foot more flue heating surface per foot in length and around the back of the boiler. With a 30ft. by 7ft. boiler this arrangement affords an extra heating surface of about 32 square feet. Over the top of the boiler, but not in contact with it, are arranged saddle-irons, which are carried down just below the top of the brickwork; at their lower ends the saddle-irons carry a longitudinal tee-bar, attached to them by an iron pin, and which, together with the brickwork, supports the flat iron flue cover, which is surmounted by the composition, making a tight joint. A compensating screw bolt is provided to move or level the saddle-irons, and as the latter are not attached to the boiler in any way, and as the flue cover is not connected with it, the boiler is free to expand without a mass of brickwork resting upon it. This type of flue cover was, in November last, fitted to a 22ft. by 7ft. Lancashire boiler at the works of the Telegraph Manufacturing Company, Limited, at Helsby. In this case two side flues and one back flue were uncovered, the soot removed, and the Taylor flue covers and composition substituted, the whole of the work being accomplished and the boiler ready for firing up in about three hours at a cost for labour of 2s. 6d. After six months' working, the ironwork of the flue covers was found to be in an excellent condition, and no deterioration was perceptible. The same company have had another boiler similarly equipped. Among the advantages claimed for this system may be mentioned that the flues can be opened and any part of the boiler examined and the flue covers replaced in less than half-an-hour; that when the covers are removed the whole of the side and end flues are open and the boiler exposed to daylight; that the flues cool down in half the time if opened, thus saving time on inspection and cleaning; that any leakage is more readily discovered and rendered accessible; that the composition is a non-conductor and can be reused at small expense, and is free from acid or anything likely to injure the boiler; and that the increased heating surface afforded by the system, and the more frequent cleaning of the flues, result in a saving of fuel and an increased horse-power obtainable from the boiler.

Electrophysiology.—Some further particulars are to hand with regard to the experiments by M. Leduc on alternating electrostatic currents. When an electrostatic machine is worked and a series of sparks apparently continuous pass between the knobs, the conductors are, as is well known, subject to variations of potential—in fact, to electric vibration. These vibrations are utilised by M. Leduc to produce other alternating or vibratory currents. If a Leyden jar is suspended by a rod from its inner coating to each of the conductors of the machine, and the external coatings of the two jars are connected by a high-resistance circuit, the internal coatings become part of the conductors. Electric vibrations of reverse nature take place at the same instant of time on the two inner coatings, one rising as the other falls, and the vibration is communicated to the outer coatings, so that on the circuit connecting them a vibratory current is set up. The resistance between the outer coatings should be such that the total capacity of the Leyden jars is proportioned to the output of the machine. If, for instance, the two coatings are connected by a circuit of negligible resistance, the conductors (of which the coatings form part) having too large a capacity, the sparks become intermittent, and a vibratory current in the true sense of the word is not obtained. But with a high resistance between the external coating, oscillatory discharges could not be produced between these coatings. The experiments were carried out with a Wimshurst machine having two glass plates 2ft. diameter. The vibratory currents obtained by the means of electrostatic machines have properties similar to but not identical with those used by Mr. Tesla. Conductors carrying these currents become luminous, and, under good experimental conditions, give from their whole surface brushlike discharges differing much in intensity and other characteristics from those of electrostatic electricity. By varying that form of the conductors and by bringing other conductors near, very varying and very beautiful luminous effects are produced. The best arrangement to carry out this experiment consists in putting one of the external coatings to earth and connecting the other with a hanging chain in contact by a point with the base of the machine. If the hanging chain of the preceding experiment is covered with an indiarubber tube, and this tube is taken in the hand, it becomes luminous as if phosphorescent by the production of short brush discharges, in the form of an aura between the hand and the tube; the sensation is not painful. If a Tesla tube is brought near to the free conductor, it lights up at a considerable distance away, and if the balls of the exciters are separated so as to suppress the alternations while increasing the tension, the tube becomes dark, and must be brought much nearer to light up again. An incandescent lamp bulb suspended on the free conductor becomes luminous, and its luminosity increases if touched. This lamp and the indiarubber tube itself are both strongly attracted by a conductor in communication with earth — by the hand, for instance. The same experiment made with static electricity gives an attraction followed by a repulsion, while with these vibratory currents only attraction is produced. These high-tension alternating currents obtained with static machines are noticed to have, as we have already mentioned, a great effect on the sensory and motor nerves. One electrode is sufficient. A blunt metallic point is used, mounted on a glass handle, attached to the free chain of one of the external coatings; this point moved over the skin, when passing a motor or sensor nerve, excites the nerve throughout its whole distribution beneath the electrode. The sensation throughout the region covered by the nerve is so plain that it allows the distribution to be mapped out. MM. Pellat, Gariel, and D'Arsonval verified these experiments of M. Leduc. But the experiment which caused the most interest and surprise was the production of muscular contraction at a distance by the aid of currents themselves produced in the human body by induction. The observer being placed between the machine and a live frog, if he moves his hand near to the frog as if to point at it with his forefinger, even at the distance of so much as a yard away, the muscles begin to contract. If the hand is moved nearer or farther away, these movements are inscribed on the myograph by this new kind of galvanoscope.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

ARC LIGHTING.

(Continued from page 56.)

Town Lighting.—The greatest field for arc lighting is undoubtedly that of the illumination of the streets and public thoroughfares of towns, and now that some of our most important cities are having central stations put down, there is great prospect that the dull, miserable gas lights will quickly disappear, to make room for the brilliant light of the electric arc. Nobody can fail to mark the great contrast presented when passing from a district lighted by arcs into one lighted by gas—the latter in comparison with the former is a region of gloom. In England it is very seldom that one comes across a town that is decently lighted by gas, and even then it is confined to the few important streets, but the progressive spirit of the age and the mode of life in this nineteenth century demand what Goethe in his dying moments vainly sought for. "Light; more light!" was the cry of that giant of intellect, and as his wonderful mind groped in the dark, so do we, in a physical sense. It is the effect of the contrast between gas and electric lighting that will do more to further the adoption of the latter than anything else. People that visit a town brilliantly lighted by the new illuminant will feel the gloom and semi-darkness of their own gas lighted town in a tenfold degree, for when a higher standard is reached, no matter in what, the old one is dwarfed in value, and as the gas flame supplanted the rushlight in its lighting powers, so will the electric light supplant gas light. Next to drainage, one of the very greatest blessings a town can have is good light and plenty of it; not merely for personal convenience in getting about in the streets, but for the whole welfare and improvement of the place. The town will score a decided advantage over its ill lighted neighbours, business is brisker, the vehicular traffic is rendered safer and more expeditious, and the general tone of the place is raised. A brightly-lighted town tends to make the inhabitants more cheerful and smart. Ill-lighted towns drive away trade and visitors, throw a despondency over all, and nurse crime as darkness does noxious plants.

In the majority of English towns the central part consists of narrow, tortuous streets huddled together, forming the old nucleus of the town, and where the town is one that has opened out and improved, wider and straighter roads will radiate out from this centre. When going into the matter of lighting a town by means of arc lamps, the plan of the town must be very carefully analysed and studied, and it is no use trying to find a precedent: each town must be considered and judged from its own advantages and disadvantages. No two are alike: each has its own local peculiarities; and every street, every square, must be thoroughly considered with regard to amount of traffic, public buildings, most suitable distribution of light, and such like details, so that the engineer must identify himself with the requirements of the town as if he were an inhabitant, and so had to participate in the lighting arrangements he is about to introduce. Planned-out roads, fairly straight, or with gentle curves, are easy enough to light; it is the rabbit-warren collection of streets that cause trouble, for light will not go round a corner, and since arc lamps are placed much farther apart than gas lamps are, it becomes difficult to light up a street that bends about. In these cases, it is perhaps best to employ arcs of small candle-power, so that they can be placed nearer together than what larger-sized lamps would be; then in the straight roads these large lamps, well apart, can be positioned where their full light will be utilised. Small and side streets, alleys, etc., are best lighted by incandescent lamps -16 c.p. or 32 c.p., according to the amount of light deemed necessary; lamps of 8 c.p. are of little use, being too feeble, and they should never be used for street-lighting. Incandescent lamps can easily be run off an arc lighting plant, and the combination of the two, judiciously placed, provide a flexible and satisfactory way of dealing with all the streets of a town, from the main thoroughfares down to the insignificant side street.

Full details of such systems will be given when the subject of distribution of electricity is reached. The positions of the gas lamps indicate best where the light is mostly wanted; they will also indicate by their distance apart the relative degree of light required in various parts of the town, so that although they do not illuminate well, they provide a good guide as to how the light should be distributed. The great art in fixing arc lamps in the streets is to always have one at a corner or junction of roads, and erected in such a position that, whether there be three or four or more roads meeting at that point, the light from the arc shall penetrate down all the roads or streets. It is at such corners and junctions that the use of the arc is shown, since the number of gas lamps which one arc will displace will increase with the number of roads which the arc commands. Suppose one arc will illuminate as far as three gas lamps at a certain distance apart, then one arc will displace three gas lamps along a straight road, and at three cross roads will displace five gas lamps, and at four cross roads as many as seven.

In small country towns, very little traffic is in the streets after 10 p.m., and most of the inhabitants are indoors, and towards midnight scarcely a solitary person is about, so that at that time one-half of the arc lamps could easily be dispensed with and switched off. This would effect a considerable saving, for in addition to the decrease of the current, and the saving of electric energy, the consumption of carbons in the lamps is reduced probably to one-half, and the lamps will require less trimming, thereby saving the trimmers' time. The incandescent lamps could not very well be diminished, being small lights, they would all be required. In the United States, when a town enters into a contract with the electric company located there to light the place with arc lamps, the moon schedule is always brought in; this means that whenever there is a full moon visible and an unclouded sky, the arcs can be switched off, since the moon supplies ample light: for every night on which the moon lights the town instead of arcs so much is taken off the contract price. The same might be done in England, but at much greater risk, because there is no knowing how the weather may change.

Where the roads are wide and the traffic permits it, the best position for the arc posts is in the centre of the road: the light is then distributed equally on each side. In the majority of places, however, it will be found that they must be placed along the kerbstone, like gas lamps, and fixed alternately on the right and left side of the road. When arc lighting was first introduced into the streets, wooden poles with a slight taper and painted dark green were used, the height being about 30ft. Now that the lighting is a proved success, it is better to erect more substantial ones in the form of light steel tubular poles or cast-iron ornamental standards. The arc lamp can be fixed on the top of the standard, or it can be hung from a bracket arrangement; this latter way is useful when the lamp is at a street corner, since it can be projected over the roadway. Chelmsford, in Essex, was the second town in England to have its streets entirely lighted by electricity, arc lamps being used for the main thoroughfares, and 32-c.p. incandescent lamps for the rest. The main artery of the town is about a mile long, and takes a right-angled course; there are 20 arcs, and therefore 20 arcs to the mile. This gives an average distance apart of 88 yards, or 264ft. In the central portion of the route they are fixed 70 to 80 yards apart, further away the distances increase to 120 to 130 yards apart. The height of these arcs is 30ft.; the writer does not know their actual candle-power.

Until lately there was no arc lamp that would burn satisfactorily with alternating currents, and there are now very few in the market that are of any use, so that there is an unexplored field open for the adaption of arc lamps for alternating currents. Since an alternating current flows first in one direction and then in another, therefore the carbon tips both become somewhat pointed, and no crater is formed on either, consequently as much light is thrown upwards as is thrown downwards, a very different case to arc lamps run with continuous currents. These upward rays are therefore wasted in street-lighting, so that small

reflectors should be provided fixed over the arc, thus throwing the upward rays towards the ground.

There is very little reliable data concerning a comparison between an alternating current arc and a direct-current arc. Some say the former gives more light than the latter for the same amount of power. There is certainly a great future before a good alternating-current arc lamp, particularly one that is adapted for running in parallel across the secondary of a high-tension alternating-current system, such as is mostly used for distributing electricity over wide areas. One curious thing about these lamps is that they emit a humming sound when burning. The cause of this is not known. It may be due to the alternate rapid heating and cooling of the carbons, promoted by the continual change of polarity.

(To be continued.)

PROPOSED ELECTRIC UNDERGROUND RAILWAY FOR BRUSSELS.

More than one proposal has been made before now to give the Belgian capital a complete and satisfactory system of rapid transit; indeed, we might almost say that if all the suggestions that have been made could be carried into effect, the Bruxellois would have nothing to do but ride about the city all day long in an overwhelming variety of vehicles—underground, above ground, and even in the air!

Not the least important of these schemes, however, is that based upon the Greathead system of deep tunnels, 50ft. or so beneath the ground-level; and the very fact of Brussels being by nature a city of hills should give such a plan the more weight because of its entire independence of surface profile. An electric line of any kind on the ordinary ground-level, and even an elevated railway, would without doubt find serious obstacles in the heavy grades to be encountered; the tramcars now running, for instance, often require three and even four horses to deal at all adequately with the traffic, whilst the speed attained is trifling compared with what could be given by any good mechanical system.

In *La Nouvelliste* of Verviers, under date of July 23, appears a large illustrated supplement dealing with this proposal, and giving the details necessary for the general public to understand such technicalities as appear essential to the scheme.

This "Projet de Chemin de fer Electrique Souterrain" is due almost entirely to the initiative of Mons. Alph. Mullender, the United States Vice-Consul for the province of Liége, and a merchant in a large way of business at Verviers.

Mons. Mullender applied at the end of last year to the Minister of Public Works for a concession which will enable this line to be undertaken and built, and the scheme now submitted embodies not only a complete plan for Brussels, but also shows what has been done elsewhere in a similar direction—notably with regard to the City and South London Railway. Although, as already stated, Brussels is by no mean without means of transit, these are looked upon as insufficient for modern requirements; what the inhabitants now call for is a service at once more rapid, more regular, and more frequent than the street tramways can possibly give. Brussels, by the way, is not singular in this respect; but let that pass. The tramway company of Brussels already carries more than 16 million passengers per annum; but this does not, it is said, represent in the least the possibilities of passenger traffic, for the reasons given. Some details of the tramway system will be of interest in this connection. With a capital of 15 million francs, a length of line equal to about 35 kilometres, rolling-stock to the extent of 108 cars, worked by 696 horses, the total receipts for the first six months of the present year reached the sum of 1½ million francs. The proportion of expenses to receipts is, however, as high as 76 per cent., owing, very largely, to the steep grades and heavy cost of working them.

Mons. Mullender, in his proposed underground system, expects not so much to enter into competition with the surface tramways as to supplement their efforts by giving methods of transit quite out of their power, but which are urgently required by the public. According to the new scheme, 11 stations would be available on the circle first constructed. The entire plan, it should be said, comprises practically one complete circle of course, with double lines—a second circle branching out from the first, following afterwards as an extension.

The length of line proposed at the outset amounts to some 6,140 metres, or, say, four miles. As in the South London line, the tunnels would be quite distinct from one another, hence avoiding all danger of accidents or stoppage of traffic between line and line.

The minimum curve radius is about three chains. The tunnels, almost without exception, would run throughout the whole of their length below the public streets; and their depth would be sufficient to ensure reliable strata in which to work. For the greater part the subsoil appears to be clay, so that a use may be found for the excavated material.

It is proposed to build the generating station on a site outside the first circle, and therefore some distance from the extension; but, of course, in a crowded city the most convenient place for a supply station is not always the cheapest, either in first cost or in daily working. The power available would, however, serve to give a 2½-minute service each way from 6 a.m. to midnight, a double staff of men being employed on a nine hour shift. It is doubtless to be expected that as a counter-balancing disadvantage the wages to be paid for this work would be less than are current in this country; otherwise a rush of labour might take place towards Belgium pending an eight-hour day over here.

The second circle—or extension of that first proposed—has four stations only on its entire length of 3,430 metres, or, say, nearly two miles. That part of the city through which this line would run is by no means well provided with rapid transit, and it is therefore expected that no little increase of revenue would result from completion of the whole plan.

The total cost of the first circle is estimated to require a capital of 17½ million francs, or, say, £700,000—a sum which would, however, only build about three miles of line instead of four, taking as a standard the £200,000 per mile of the South London Railway. The working expenses per annum are estimated at 750,000f. (= £30,000); whilst a sinking fund equal to 886,000f. (£35,000) would bring this up to 1,636,000f. (£65,000). Fares over the whole line for any distance are to be 20 centimes—say, 2d.—second class, and 30 centimes (3d.) first class.

The appearance of the station buildings on the street-level closely resembles that of the ordinary tramway waiting rooms, a short staircase leading down to a large hall beneath the pavement, with ticket office, and entrances to the lifts working up and down to the platforms. The design of these lifts is of the usual type worked by water pressure, and made to contain 40 persons. Of course safety appliances are provided for.

It is hardly worth while going into the estimates of probable working cost and receipts on the proposed line; conclusive proof has been afforded by the South London Railway that an underground electric line can be made to pay if the traffic exists. The financial aspect, however, deserves separate treatment. F. B. L.

THE ACTION OF COMPOUND DYNAMOS WHEN RUN IN PARALLEL.*

BY WILLIAM L. PUFFER, S.B.

(Concluded from page 17.)

There is a very safe and simple method of throwing in a new dynamo, which does not, however, prevent a change in the switchboard voltage unless a special switch is used as shown in Fig. 6, constructed in such a way that the equalising connection is first made and then the outside end of the series coil gradually connected by a switch with a few

* From *Technology Quarterly*, vol. v., No. 4, December, 1892.

resistance points in it, while at the same time the magnetising effect of the shunt coil of the loaded dynamo is increased to make up for the loss in the series coil In this way the series coils can be put in parallel with no jump in the voltage. If, however, there are many similar dynamos in the plant, it might be that the change produced by throwing in a series coil without its armature would not produce a greater change than would be allowable; in such a case the safest way is to connect first the series coils, then rapidly adjust the armature voltage by the voltmeter, or, if in a great hurry, by the looks of the pilot lamps, and then close the armature switch, well knowing that the steep net falling characteristic of the armature circuit will prevent an overload.

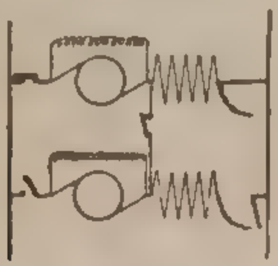

FIG. 6.

The common three-pole switch generally used can easily be changed so as to admit of working in this way by cutting through the top of the insulating bushing and putting a separate handle on the blade which closes the armature lead to the 'bus wire; then pulling the ordinary handle out will open all blades at once, but pushing it in will only connect the series coils, leaving the armature circuit open. If the wiring is so that the series coils are permanently connected and a new dynamo is thrown in by a single-pole switch, we have here a very wide range of voltages for the new dynamo, and pilot lamps may be used to judge the voltage. We have two 'bus bars with all the series coils joined between them; evidently, then, the total current flowing from bar to bar will simply divide between those coils inversely as their respective resistances, and we shall, in consequence, have the voltage of the armature 'bus bars rising and falling with the total current from the plant; and if the machines are similar all of the armature voltages will rise and fall together. If this is so, and it cannot be otherwise, these armatures are to be considered simply as net falling characteristic armatures working in parallel between the equalising bar and the third 'bus bar, and the division of the load between them will take place exactly as has been previously shown for common shunt dynamos, and therefore, inasmuch as we have a very decided net falling characteristic, there is but little danger of an overload on a new dynamo armature.

FIG. 7.

It is now clear that when we wish such dynamos to run together we must first adjust the resistances of all the series coils and connections, so that when a current is passing through them but not through the armatures, the armature voltages must be equally affected; and also see that the armature circuits are so arranged as to give the same net falling characteristics independent of the series coils. It is necessary for good compounding to have the brushes set once for all, and in all well designed dynamos it is possible to find a point where there will be no excessive sparking. An easier although not so good a way to adjust is to find the best point for the lead, and then alter the resistances of the series coils until all dynamos have the same net characteristics; but the rise of voltage due simply to the flow through all the series coils will in this case be different in different dynamos, and there will be a little more difficulty in adding a new dynamo, and a tendency to overload.

Nearly all of the compound dynamos in the market for the last few years are purposely built with too many turns in the series coil, and then a shunt of German silver is adjusted by trial at the factory until the voltage at the terminals show the wished-for "0 per cent. rise," or whatever it might be Now, for any one dynamo running under the conditions of the experimental trial this method is simple and perfectly correct; but when such dynamos are run together in multiple it is of no service, and has no effect on the relative actions of the series coils of the dynamos, because of the fact that all coils and all shunts become parallel conductors, and therefore traverse by currents inversely proportional to their resistances. These shunts then merely diminish the total flow of current through the series coils, but in no way do they serve to adjust the effect of the series coils relatively to each other. If it should happen that one dynamo was very much over-compounded and then shunted for the "0 per cent. rise," and another only very slightly over-compounded, and consequently only slightly shunted, it is plain that when the shunted series coils are in parallel the shunts will have only the effect of affording a path for a part of the total flow of current, and consequently could be wired up in any convenient place on the switchboard. These two above-mentioned dynamos would then be dissimilar over-compounded machines working in parallel, and in all probability an increasing load would be largely carried by the dynamo with most turns in the series coil, because an increase in total current flowing through the series coils would promote the voltage of this dynamo faster than that of the other. This will be the familiar condition we often see in power plants where the average load is equally divided, while an overload is taken quicker by the dynamo which takes the loss at light loads—that is, the one in which the series coils have greatest effect.

In order to make such dynamos work properly it is best to examine the lead and the wiring, and, if possible, give the armatures similar net falling characteristics, and then, by the use of copper or German-silver ribbon, slightly change the resistance of the series coils until all armatures are equally affected by the flow of current in the series coils, a single large shunt may be connected at any part of the bars to which the series coils are attached, or perhaps better, each machine may have a shunt across the series connections at the switchboard, on the dynamo side of the main three-pole switch, so that the total shunting capacity varies, as it ought, with the number of dynamos running.

After one of my lectures a few weeks ago two young men asked me for an explanation of what seemed to them a very strange phenomenon which always occurred when a large dynamo was cut out of service; and as it is a very good practical example of the use of multiple characteristics as I have shown them, I will give it. In a railroad power-house are about 16 100-h.p. "0 per cent. rise" dynamos, and one large 500-h.p. "0 per cent. rise" dynamo, all provided with shunts. Ordinarily the machines all do well enough, but as the load gets light at night and the big one is cut out the voltage rises instantly about 30 volts in some unexplained manner. May not this be the reason? The series coil and shunt of the large dynamo are of so low resistance that they carry a large part of the total current in all the series coils and shunts. Now, when the machine is to be cut out, the current in the armature is cut down by the rheostat in the shunt field circuit to as nearly as may be nothing; but this current is in this way slowly shifted to the other 16 armatures, causing a slight fall in voltage due to the net falling armature characteristics, which drop is not counteracted by the series coils because there has been no change in the distribution of the total current. This slight fall is probably not especially noticeable, but the sudden jump comes when the series coils and shunt ribbon of the 500 h.p. dynamo are cut out of circuit and the large current in them is instantly transferred to the series coils of the other smaller dynamos. If the switches were made to stand the arcing, I doubt if there would be much change noticed if the dynamos were simply disconnected without gradually diminishing the armature current.

It has been supposed in this paper that there is no such a thing as time required to change the strength of dynamo magnets, and that there is no difference between the

ascending and descending magnetising curve of iron. These time effects will not come in for ordinary fluctuations if the net armature characteristics are similar, and consequently the required changes in all the magnets would be of the same amounts, and would, therefore, take nearly the same time; for sudden changes like a short circuit it is not likely that the load would divide equally, but it would be very much nearer so than with the ordinary unadjusted dynamos, and a heavier short circuit could be burned out than with unadjusted dynamos, where some would rapidly overload and open their circuit breakers and thereby precipitate a general breakdown.

In large plants where more than one dynamo is driven by a single engine and there are several engines, it will be found of advantage to adjust each set of dynamos so that they will work well together, and then adjust each engine load for engine speed change. To do this, each dynamo on a single engine would have its series coil and shunt properly adjusted until, as far as that particular engine load is concerned, the load would be equally divided between the armatures; then the sets of series coils corresponding to the different engines would be connected through a small resistance to the station 'bus bar, and we should find that the total load could be evenly divided between the engines. The arrangement of these resistances is indicated in Fig 7, which shows three engines, each driving three dynamos by belts or any convenient way. The three series coils of each unit are adjusted so that a changing load will be equally shared by each dynamo, and then the three coils are shunted until the desired compounding is attained. It is now necessary to compensate for any difference there

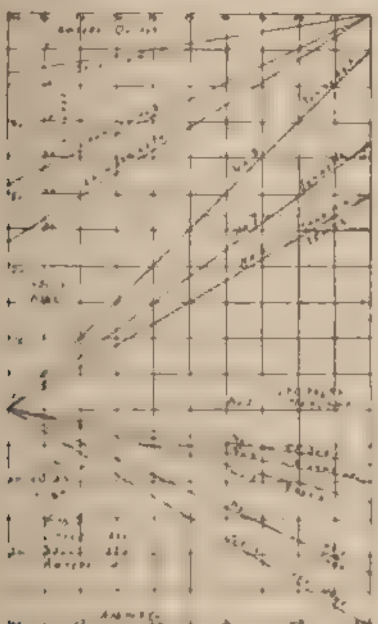

Fig. 8.

may be in the speed regulation of the engines or in the main belt slips by a slight change in the total resistance of the three sets of parallel series coils. There will be, of course, the usual precautions necessary when throwing in or cutting out a set of dynamos, and the most satisfactory way, if steady voltage is to be desired, will be to close the three large main switches at once by steam or other power acting upon heavy switches built to stand the arcing of such currents, thus connecting simultaneously the three 'bus bars to the station main bars; the same method should be used to disconnect when the time comes for stopping an engine.

In order to study the action of dynamos which were exactly similar in all respects, except the magnetising effects of their series coils, a number of turns of wire was wound upon the magnet spools of dynamo No. 2 and connected in series with the regular windings, and the resistance of the series coils of dynamo No. 1 was made equal to that of No. 2 by the addition of a length of copper wire. Each dynamo was then fitted with the usual German-silver shunt of such resistance that the net result was a constant potential at the terminals. The various curves of these dynamos are plotted in Fig. 8, and may be described as follows: Curve 3 gives the fall of potential or drop in volts due simply to the fall in speed as the load on the dynamo increases, and is the same for each separately driven dynamo. Curve 4 gives the drop in volts in the total armature circuit from equaliser wire, which will be considered as a 'bus bar to main 'bus bar, and does not include the drop in the series coils and connection to the 'bus bar which is given separately in curve 5.

Curve 0 is the sum of curves 3, 4, and 5, and represents the total drop in each dynamo when running independently, due to all reactions; while curve 1 is the sum of 3 and 4, or the total drop if we consider the series coil as a part of the external circuit. Curves 7 and 8 show respectively the rise in voltage due to the current in the series coils of each dynamo, and it will be seen that for the same current value dynamo No. 2 has a somewhat more powerful series coil. Curve 6, being the equal and opposite of curve 0, shows the rise in volts which each dynamo must have in order to maintain a constant potential at its terminals; and therefore a horizontal line cutting curve 6, as, for example, at the rated current of 45 amperes, will cut the curves 7 and 8 at points whose corresponding current values are those which will produce the required magnetising force, and the difference between these current values and the rated current must be carried by the shunts on the series coils.

The series coils of each dynamo were adjusted to a resistance of ·15 ohm, and the series coil shunt of dynamo No. 1 had a resistance of about ·60 ohm, and would carry at full load about nine amperes, leaving 36 amperes to produce the rise of 27 volts necessary to neutralise the total drop taken from curve 0. To produce the same rise in No. 2 dynamo required a shunt of about ·22 ohm carrying 18 amperes, leaving but 27 for the series coils.

These two dynamos are now in such a condition that according to the usual practice it would be perfectly proper to run them in parallel with the expectation that everything would work well; however, such is not the case, as may be seen from the curves, and as was proved by the actual effects obtained.

When the two series coils with their shunts are thrown in parallel the total flow of current through them will divide inversely as the resistances of the four circuits, which are, as we have just seen, two series coils each of ·15 ohm, one shunt of ·60 ohm, and one of ·22 ohm. If we call the total current 100, these four circuits will carry respectively about 33·7, 33·7, 8·4, and 24·1, and as the total output of the two armatures may safely be 100 amperes, the above figures give the strength of current in these circuits.

At the top of Fig. 8 is a scale reading from right to left up to 100 amperes, and near the left-hand side a scale reading downwards up to 30 amperes; the three inclined lines enable us to read at once the actual current in the two shunts and the two series coils for any output of the dynamos when running in parallel.

It has already been shown that each dynamo is individually capable of maintaining a constant potential at the 'bus bars independently of the current flowing, and it has been stated that the dynamos will not work well in parallel. Suppose that the dynamos are connected in parallel at 220 volts under no load, and that a current of 90 amperes, which is equal to the rated load of the two dynamos, is taken from the bus bars. To find the currents in the series coils we find under 90 amperes total output that each series coil will carry 30·4 amperes; the shunt on No. 1, 7 6 amperes; and the shunt on No. 3, 21·6 amperes.

No. 1.	No. 2.	
220	220	Volts at no load.
+ 22 5	+ 30 2	Rise from curves 7 and 8 at 30 4 amperes.
242 5	250·2	Total armature voltage.
	− 7 7	Fall of volts due to 17 amperes, curve 1. No. 2 can deliver current producing a fall of 250 2 − 242·5 before No 1 begins to act as a dynamo at all, and after that both armatures will divide the remainder, or 90 − 17 = 73, and the total drop is taken from curve 1 for one half the difference, or 36 5 amperes.
242·5	242 5	
− 16 5	− 16 5	Drop with 36 5 amperes, curve 1.
226 0	226·0	Armature 'bus bar voltage.
6 5	6 5	Drop in the series coil giving for the main 'bus bars 220 5 volts with an output of 36 5 amperes from dynamo No. 1, and 53 5 from No. 2.
220·5	220 5	

As an interesting example of the different degree of badness which may be produced when two individually well-adjusted dynamos are run in parallel, let us suppose that these two dynamos are placed in proper alignment, and one large driving pulley slipped over the ends of the shafts, as is very often done, thus making the armatures run at the same speed with the same per cent. belt slip, which will bring the resultant voltage about the same as in the previous example.

No. 1.	No. 2.	
220	220	Volts at no load.
22·5	+ 30·2	Rise from curves 7 and 8 as before.
242·5	250·2	Total armature voltage.
	- 7·7	Fall of volt due to 38 amperes. Curve 4.
242·5	242·5	Dynamo No. 2 must deliver a current producing a fall of volts equal to the difference of the armature voltages before No. 1 will deliver any current. The remaining current will divide equally, producing a fall found in curve 4.
- 5·2	- 5·2	Fall with 26 amperes. Curve 4.
237·3	237·3	
- 6·5	6·5	Drop in series coils. Curve 5.
230·8	230·8	
- 11·2	11·2	Belt slip. Curve 3.
219·6	219·6	Voltage on main 'bus bars with an output of 26 amperes from dynamo No. 1, and 64 from No. 2.

COMPARATIVE TABLE.

ON LIGHT AND OTHER HIGH-FREQUENCY PHENOMENA.*

BY NIKOLA TESLA.

(Continued from page 64.)

As regards the rise of potential through resonant action, of course, theoretically, it may amount to anything, since it depends on self induction and resistance, and since these may have any value. But in practice, one is limited in the selection of these values, and besides these, there are other limiting causes. One may start with, say, 1,000 volts, and raise the E M F to 50 times that value, but one cannot start with 100,000 and raise it to 10 times that value because of the losses in the media, which are great, especially if the frequency is high. It should be possible to start with, for instance, two volts from a high or low frequency circuit of a dynamo and raise the E.M.F. to many hundred times that value. Thus coils of the proper dimensions might be connected each with only one of its ends to the mains from a machine of low E.M F., and though the circuit of the machine would not be closed in the ordinary acceptance of the term, yet the machine might be burned out if a proper resonance effect would be obtained. I have not been able to produce, nor have I observed with currents from the dynamo machine, such great rises of potential. It is possible, if not probable, that with currents obtained from apparatus containing iron the disturbing influence of the latter is the cause that these theoretical possibilities cannot be realised; but if such is the case, I attribute it solely to the hysteresis and Foucault current losses in the core. Generally it was necessary to transform upward, when the E M F. was very low, and usually an ordinary form of induction coil was employed, but sometimes the arrangement illustrated in Fig 20 II. has been found to be convenient. In this case a coil, C, is made in a great many sections, a few of these being used as the primary. In this manner both primary and secondary are adjustable. One end of the coil is connected to the line, L_1, from the alternator, and the other line, L, is connected to the intermediate point of the coil. Such a coil with adjustable primary and secondary will be found also convenient in experiments with the disruptive discharge. When true resonance is obtained, the top of the wave must of course be on the free end of the coil, as for instance, at the terminal of the phosphorescence bulb, B. This is easily recognised by observing the potential of a point on the wire, w, nearer to the coil.

In connection with resonance effects and the problem of transmission of energy over a single conductor which was previously considered, I would say a few words on a subject which constantly fills my thoughts, and which concerns the welfare of all. I mean the transmission of intelligible signals, or perhaps even power to any distance without the use of wires. I am becoming daily more convinced of the practicability of the scheme; and though I know full well that the great majority of scientific men will not believe that such results can be practically and immediately realised, yet I think that all consider the developments in recent years by a number of workers to have been such as to encourage thought and experiment in this direction. My conviction has grown so strong that I no longer look upon this plan of energy or intelligence transmission as a mere theoretical possibility, but as a serious problem in electrical engineering, which must be carried out some day. The idea of transmitting intelligence without wires is the natural outcome of the most recent results of electrical investigations. Some enthusiasts have expressed their belief that telephony to any distance by induction through the air is possible. I cannot stretch my imagination so far, but I do firmly believe that it is practicable to disturb by means of powerful machines the electrostatic condition of the earth and thus transmit intelligible signals and perhaps power. In fact, what is there against the carrying out of such a scheme? We now know that electric vibration may be transmitted through a single conductor. Why then not try to avail ourselves of the earth for this purpose? We need not be frightened by the idea of distance. To the weary wanderer counting the mile-posts the earth may appear very large, but to that happiest of all men, the astronomer, who gazes at the heavens and by their standard judges the magnitude of our globe, it appears very small. And so I think it must seem to the electrician, for when he considers the speed with which an electric disturbance is propagated through the earth all his ideas of distance must completely vanish.

A point of great importance would be first to know what is the capacity of the earth? and what charge does it contain if electrified? Though we have no positive evidence of a charged body existing in space without other oppositely electrified bodies being near, there is a fair probability that the earth is such a body, for by whatever process it was separated from other bodies—and this is the accepted view of its origin—it must have retained a charge, as occurs in all processes of mechanical separation. If it be a charged body insulated in space its capacity should be extremely small—less than one-thousandth of a farad. But the upper strata of the air are conducting, and so, perhaps, is the medium in free space beyond the atmosphere, and these may contain an opposite charge. Then the capacity might be incomparably greater. In any case it is of the greatest importance to get an idea of what quantity of electricity the earth contains. It is difficult to say whether we shall ever acquire this necessary knowledge, but there is hope that we may, and that is, by means of electrical resonance. If ever we can ascertain at what period the earth's charge, when disturbed, oscillates with respect to an oppositely electrified system or known circuit, we shall know a fact possibly of the greatest importance to the welfare of the human race. I propose to seek for the period by means of an electrical oscillator, or a source of alternating electric currents. One of the terminals of the source would be connected to earth, as, for instance, to the city water-mains, the other to an insulated body of large surface. It is possible that the outer conducting air strata or free space contains an opposite charge and that, together with the earth, they form a condenser of very large capacity. In such case the period of vibration may be very low and an alternating dynamo machine might serve for the purpose of the experiment. I would then transform the current to a potential as high as it would be found possible and connect the ends of the high tension secondary to the ground and to the insulated body. By varying the frequency of the currents and carefully observing the potential of the insulated body and watching for the disturbance at various neighbouring points of the earth's surface resonance might be detected. Should, as the majority of scientific men in all probability believe, the period be extremely small, then a dynamo machine would not do and a proper electrical oscillator would have to be produced, and perhaps it might not be possible to obtain such rapid vibrations. But whether this be possible or not, and whether the earth contains a charge or not, and whatever may be its period of vibration, it certainly is possible—for of this we have daily evidence—to produce some electrical disturbance sufficiently powerful to be perceptible by suitable instruments at any point of the earth's surface.

Assume that a source of alternating currents, S, be connected, as in Fig 21, with one of its terminals to earth (conveniently to the water-mains) and with the other to a body of large surface, P. When the electric oscillation is set up there will be a movement of electricity in and out of P, and alternating currents will pass through the earth, converging to, or diverging from, the point, C, where the ground connection is made. In this manner neighbouring points on the earth's surface within a certain radius will be disturbed. But the disturbance will diminish with the distance, and the distance at which the effect will still be perceptible will depend on the quantity of electricity set in motion. Since the body, P, is insulated, in order to displace a considerable quantity the potential of the source must be excessive, since there would be limitations as to the surface of P. The conditions might be adjusted so that the generator or source, S, will set up the same electrical movement as though its circuit were closed. Thus it is certainly practicable to impress an electric vibration, at least of a certain low period upon the earth, by means of proper machinery. At what distance such a vibration might be made perceptible can only be conjectured. I have on another occasion considered the question how the earth might behave to electric disturbances. There is no doubt that since in such an experiment the electrical density at the surface could be but extremely small considering the size of the earth, the air would not act as a very disturbing factor, and there would be not much energy lost through the

* A lecture delivered before the Franklin Institute, at Philadelphia, February 24, 1893; and before the National Electric Light Association, at St. Louis, Mo., March 1, 1893.

action of the air, which would be the case if the density were great. Theoretically, then, it could not require a great amount of energy to produce a disturbance perceptible at a great distance, or even all over the surface of the globe. Now it is quite certain that at any point within a certain radius of the source, S, a properly-adjusted self-induction and capacity device can be set in action by resonance. But not only can this be done but another source, S_1 (Fig. 21) similar to S, or any number of such sources can be set to work in synchronism with the latter and the vibration thus intensified and spread over a large area, or a flow of electricity produced to or from the source S_1 if the same be of opposite phase to the source S. I think that beyond doubt it is possible to operate electrical devices in a city through the ground or pipe system by resonance from an electrical oscillator located at a central point. But the practical solution of this problem would be of incomparably smaller benefit to man than the realisation of the scheme of transmitting intelligence or perhaps power to any distance through the earth or environing medium. If this is at all possible, distance does not mean anything. Proper apparatus must first be produced by means of which the problem can be attacked, and I have devoted much thought to this subject. I am firmly convinced that it can be done, and hope that we shall live to see it done.

Fig. 21

Energy Transmission to Any Distance Without Wires.

On the Light Phenomena Produced by High-Frequency Currents of High Potential and General Remarks Relating to the Subject.

Returning now to the light effects which it has been the chief object to investigate, it is thought proper to divide these effects into four classes: (1) incandescence of a solid; (2) phosphorescence; (3) incandescence or phosphorescence of a rarefied gas; and (4) luminosity produced in a gas at ordinary pressure. The first question is, How are these luminous effects produced? In order to answer this question as satisfactorily as I am able to do in the light of accepted views, and with the experience acquired, and to add some interest to this demonstration, I shall dwell here upon a feature which I consider of great importance, inasmuch as it promises besides to throw a better light upon the nature of most of the phenomena produced by high frequency electric currents. I have on other occasions pointed out the great importance of the presence of the rarefied gas, or atomic medium in general, around the conductor through which alternate currents of high frequency are passed, as regards the heating of the conductor by the currents. My experiments described some time ago have shown that the higher the frequency and potential difference of the currents, the more important becomes the rarefied gas in which the conductor is immersed as a factor of the heating. The potential difference however, is, as I then pointed out, a more important element than the frequency. When both of these are sufficiently high, the heating may be almost entirely due to the presence of the rarefied gas. The experiments to follow will show the importance of the gas, or generally of gas at ordinary or other pressure as regards the incandescence or other luminous effects produced by currents of this kind.

I take two ordinary 50-volt 16 c.p. lamps which are in every respect alike, with the exception that one has been opened at the top and the air has filled the bulb, while the other is at the ordinary degree of exhaustion of commercial lamps. When I attach the lamp which is exhausted to the terminal of the secondary of the coil, which I have already used as in experiments illustrated in Fig. 15a, for instance, and turn on the current, the filament, as you have before seen, comes to high incandescence. When I attach the second lamp, which is filled with air, instead of the former, the filament still glows, but much less brightly. This experiment illustrates only in part the truth of the statements before made. The importance of the filaments being immersed in rarefied gas is plainly noticeable, but not to such a degree as might be desirable. The reason is that the secondary of this coil is wound for low tension, having only 150 turns, and the potential difference at the terminals of the lamps is therefore small. Were I to take another coil with many more turns in the secondary, the effect would be increased, since it depends partially on the potential difference, as before remarked. But since the effect likewise depends on the frequency, it may be properly stated that it depends on the time rate of the variation of the potential difference. The greater this variation, the more important becomes the gas as an element of heating. I can produce a much greater rate of variation in another way, which besides has the advantage of doing away with the objections which might be made in the experiment just shown, even if both the lamps were connected in series or multiple arc to the coil—namely, that in consequence of the reactions existing between the primary and secondary coil the conclusions are rendered uncertain. This result I secure by charging from an ordinary transformer, which is fed from the alternating current supply station, a battery of condensers, and discharging the latter directly through a circuit of small self-induction, as before illustrated in Figs. 19a, 19b, 19c.

In Figs. 22a, 22b, and 22c, the heavy copper bars, B B_1, are connected to the opposite coatings of a battery of condensers, or generally in such way that the high-frequency or sudden discharges are made to traverse them. I connect first an ordinary 50-volt incandescent lamp to the bars by means of the clamps, c c. The discharges being passed through the lamp, the filament is rendered incandescent, though the current through it is very small, and would not be nearly sufficient to produce a visible effect under the conditions of ordinary use of the lamp. Instead of this I now attach to the bars another lamp exactly like the first, but with the seal broken off, the bulb being therefore filled with air at ordinary pressure. When the discharges are directed through the filament, as before, it does not become incandescent. But the result might still be attributed to one of the many possible reactions. I therefore connect both the lamps in multiple arc, as illustrated in Fig. 22a. Passing the discharges through both the lamps, again the filament in the exhausted lamp, l, glows very brightly, while that in the non-exhausted lamp, l_1, remains dark, as previously. But it should not be thought that the latter lamp is taking only a small fraction of the energy supplied to both the lamps; on the contrary, it may consume a considerable portion of the energy, and it may become even hotter than the one which burns brightly. In this experiment the potential difference at the terminals of the lamps varies in sign theoretically three to four million times a second. The ends of the filaments are correspondingly electrified, and the gas in the bulbs is violently agitated, and a large portion of the supplied energy is thus converted into heat. In the non-exhausted bulb there being a few million times more gas molecules than in the exhausted one, the bombardment, which is most violent at the ends of the filament, in the neck of the bulb, consumes a large portion of the energy without producing any visible effect. The reason is that there being many molecules, the bombardment is quantitatively considerable, but the individual impacts are not very violent, as the speeds of the molecules are comparatively small owing to the small free path. In the exhausted bulb, on the contrary, the speeds are very great and the individual impacts are violent, and therefore better adapted to produce a visible effect. Besides, the convection of heat is greater in the former bulb. In both the bulbs the current traversing the filaments is very small, incomparably smaller than that which they require in an ordinary low frequency circuit. The potential difference, however, at the ends of the filaments is very great, and might be possibly 20,000 volts or more if the filaments were straight and their ends far apart. In the ordinary lamp a spark generally occurs between the ends of the filament or between the platinum wires outside, before such a difference of potential can be reached.

Showing the Effect of the Presence of a Gaseous Medium.

It might be objected in the experiment before shown that the lamps, being in multiple arc, the exhausted lamp might take a much larger current and that the effect observed might not be exactly attributable to the action of the gas in the bulbs. Such objections will lose much weight if I connect the lamp in series, with the same result. When this is done and the discharges are directed through the filaments it is again noted that the filament in the non-exhausted bulb, l_1, remains dark, while that in the exhausted one, l, glows even more intensely than under its normal conditions of working, Fig. 22b. According to general ideas the current through the filaments should now be the same, were it not modified by the presence of the gas around the filaments.

At this juncture I may point out another interesting feature, which illustrates the effect of the rate of change of potential of the currents. I will leave the two lamps connected in series to the bars, B B_1, as in the previous experiment, Fig. 22b, but will presently reduce considerably the frequency of the currents, which was excessive in the experiment just before shown. This I may do by inserting a self-induction coil in the path of the discharges, or by augmenting the capacity of the condensers. When I now pass these low frequency discharges through the lamps, the exhausted lamp, l, again is as bright as before, but it is noted also that the non-exhausted lamp, l_1, glows, though not quite as intensely as the other. Reducing the current through the lamps, I may bring the filament in the latter lamp to redness, and though the filament in the exhausted lamp, l, is bright, Fig. 22c, the degree of its incandescence is much smaller than in Fig. 22b, when the currents were of a much higher frequency.

'BUS LIGHTING.

Mr. Freund would perhaps have been wise if he had remained silent under our exceptionally mild criticism of his paper. His letter in another column compels us to further justify our previous remarks, and to show how utterly untrustworthy his estimates are. If, in the first instance, our readers will compare our remarks on page 3 of our issue of July 7 with his comments, they will see that his reply is very roundabout. Is it right to estimate for lamps at a lower figure than they can be obtained now without explaining why you put that lower figure? He tells us that the company he speaks for is ready to undertake work on this estimate now, and thereby on his own figures and knowledge either to incur a considerable loss or to use lamps not obtained from those who control the existing patents. Enough, however, as to the lamps. Our contention is that Mr. Freund's estimate is misleading, and this can be shown by examining figures open to all. We will now examine another item in his estimate, and ask Mr. Freund to justify it by appeal to the future or in any way he likes. We say it is misleading, and further, we contend that such statements do a vast amount of harm in the industry, and those who make them should be called to book. We are told that a five-candle lamp is used on an average six hours per night, and the cost of electric current for 200 of these lamps for one year is £50. We must assume that each 'bus runs 365 days in the year, though, if it is any pleasure to Mr. Freund, we would make it a score or two less. This, at six hours a day, gives 2,190 hours for each lamp. We may also assume that each lamp takes 18 watts—that is, each lamp uses about 39½ Board of Trade units in the year. But the quantity put into the batteries in order to supply this is at least 25 per cent. more; and you have to pay for what you put into the battery, not for what you usefully take out. Therefore we may take it that each lamp will cost the amount chargeable for 48 units. How do you obtain your electrical energy for charging? If, when a suitable central station exists, probably from the supply mains, at a cost of from 3d. per unit upwards. Take 3d. as the cost. Then the 48 units per lamp cost you 12s. a year, and the cost for 200 such lamps is £120. Mr. Freund says £50. How does he get his £50? We have shown how we make that item at least £120, and probably in the vast majority of cases it will be nearer £200. So far as we can see, Mr. Freund has, and can only have, one answer to this if he attempts to justify himself, and that is to point out that some central stations claim to generate their electrical energy at a much lower figure than 3d. One, indeed, claims to be able to generate a Board of Trade unit at a cost under 1d. But surely Mr. Freund does not expect his readers to understand that if they light their 'buses with his lamps and batteries they will get their energy at anything approaching these figures, even if they put up an installation of their own for 200 'buses? It is perfectly evident, however, that the estimate in the paper contemplates charging from supply mains,

as it includes a rent of £10 a year for a "charging" station. We will recapitulate our figures so as to obviate the chance of Mr. Freund not understanding them:

5-c.p. lamp require 18 watts.

Each lamp runs 2,190 hours.

And thus uses per year 2,190 × 18 watts, or about 39½ Board of Trade units.

39½ units + losses require charging energy = 48 units.

48 units at 3d. per unit cost 12s.

∴ 200 lamps cost at 12s. per lamp = £120.

Mr. Freund may have been most conscientious in getting his figures from actual results, but they are not conclusive, and the profession generally would like to know a little more about the methods by which the figures in his estimate have been obtained.

We have now commented upon two of Mr. Freund's items. The lamps, it is explained, will be obtainable at the price named some time hence. In this connection, however, there is something more to say. The lamp-hours as given in the paper amount to 2,190. Taking only four replacements in the year, that gives a lamp life as 518 hours, nearly. We do not wish to cavil at this, but should like to have proof that under the conditions of 'bus-lighting the life is so long. Admitting that the existing lamps have a life of over 500 hours, we can hardly expect that in the near future new manufacturers selling at a third or fourth the price will produce a lamp of equally long life. If Mr. Freund is ready, as he says he is, to charge batteries for £50 for the charging current to run 200 5-c.p. lamps for 2,190 hours, he must, we think, have discovered something in connection with electrical energy and accumulators not generally known, and which, if on these figures admitting an ordinary manufacturer's profit, should revolutionise all our ideas of electrical work. Put in another way, he offers to energise a 5-c.p. lamp for a week, six hours each day, for 1·17 pence—forty-two hours for 1·17 pence. We confess to an utter inability to understand the figures. If they have been conscientiously examined, how is it done? Mr. Preece has said the electric light is the poor man's light, or something to that effect, but here we have a presumably responsible business man offering to supply current to run a 5-c.p. lamp six hours a day for a week for 1·17 pence. Prodigious! Prodigious!!

OBITUARY.

THE LATE SAMUEL EDMUND PHILLIPS.

It is with deep regret we have to record the death of Mr. Samuel Edmund Phillips, which occurred somewhat suddenly at his residence at Shooter's Hill, Kent, on Saturday last. He had been in failing health for some years, and suffered greatly from an internal complaint which proved to be caused by an ulcer.

Mr. Phillips, when a boy, was brought into contact with telegraphy, his father being at that time engaged with Dr. Whitehouse in carrying out experimental work in connection with the first Atlantic cable. He subsequently accompanied his father in the first Malta and Alexandria cable expedition, and in 1863 he became a member of the staff which Colonel Patrick Stewart formed to go out with the Persian Gulf cable, remaining at Bushire as a junior clerk. At the end of three years' service he returned to England, and obtained an appointment on the electrical staff of Messrs. Latimer Clark, Forde, and Co., leaving these gentlemen to become electrician to Mr. W. T. Henley, in whose service he remained for 10 years. At Mr. Henley's works he was appointed manager of the cable department, and occasionally he accompanied cable expeditions as head of the electrical department. In 1875 he joined Mr. W. Claude Johnson in partnership, and a small works was established at Charlton. This formed the nucleus of the present extensive range of factories which are so well known to all connected with the electrical industry throughout the world.

As an inventor Mr Phillips has given us the oil insulator, which has not only been largely adopted for telegraph lines in India, Egypt, and other countries, but has proved of immense value for overhead lines for electric lighting and the transmission of power in all quarters of the globe.

Mr. Phillips took the keenest interest in scientific matters generally, and to his good judgment and sound common sense may be attributed in a great measure the success of his undertakings. His genial manner and generous nature made him a universal favourite, and his loss will be deplored by a very wide circle of friends and acquaintances. It is not customary even in deploring the loss of an old and valued friend to abstain from the impersonal, yet we cannot help saying that the late Mr. Phillips was one of those quiet, unobtrusive men to whom England owes so much. He, in common with his surviving partner, was imbued with the view that it is necessary for a firm's success to have a reputation for thoroughness, and together they built up a reputation for the firm's work that gives it a foremost place among our manufacturers.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ACCUMULATOR TRACTION.

SIR,—If this little controversy has done nothing else, it appears to have thoroughly roused Mr. Sellon's interest in accumulator traction, judging from his powerful thirst for information. Birmingham furnishes the first, and at present the only, instance where our accumulators are being used on tramways, but what of that? A beginning must needs be made somewhere, and we have begun in Birmingham, making a right satisfactory start, too, while we were about it, for Mr. Carruthers Wain, the managing director of the line, expressed himself about our cells at the recent meeting of the Tramways Institute that they leave nothing to be desired. With these two essential points, "efficiency" and "durability" of our accumulators, proved and vouched for (see our previous letters), the cost of application is readily arrived at. But, first of all, Mr. Sellon wonders why an accumulator-car service is more regular and reliable than that where either the overhead or the conduit system is used, and wants to know the reasons. To make this quite clear, we need only to consider and compare the possible causes of stoppages on the various systems.

Eliminating damage to the cars, motors, and gearings as possibilities common to all three varieties, we have to deal with the supply of current to the motors and the interruptions which may occur. On accumulator cars a substantial switch is between cells and motor, and no matter what be the movements of the car there is always a sound solid connection to the source of supply. Now, compare this with the jumpy nature of a trolley contact, which has to be fished back into its place so frequently that in America "your trolley's off" has become proverbial. This happens when current is obtainable, but stretches of cable and wire are between supply station and motor, and the wire is liable to and does snap, or in winter it is occasionally coated with ice or the rails are flooded, rendering contact very imperfect; again, the trolley pole may break (a case in point was recorded in the *Electrician* of June 14, 1893, page 279, when a man had to stand on the roof of the car and hold the trolley to the overhead wire). No one will say that such occurrences are conducive to regularity. In the conduit system the slot frequently becomes clogged

with sand and street refuse, when the passengers may vary the monotony of a ride by pushing the car beyond the obstruction. But, above all, with the trolley or conduit system a temporary breakdown of the machinery at the central station may cause a stoppage along the entire line, whereas on the accumulator system only the one car is affected in which the cells have come to an end of their charge, and this can be pushed on by the car following it. The daily returns at Birmingham fully corroborate our assertion, showing that the service on the Bristol-road line has been practically free from interruptions.

Now, as to the cost of motive power per car mile of cars fitted with our accumulators, this we give herewith, and are quite prepared to stand by our figures at any time:

Line: 3 miles, double track.
Cars: 12, each for 52 passengers.
Weight: 12 tons.
Service: 5 minutes.
Speed: 6 miles per hour, including stoppages.
Time: 15 hours per day = 90 car miles.

	Cost per week.				Pence per car mile.
Fuel, 70s. per day	£24	10	0	...	·778
Oil, waste, and sundries	4	0	0	...	·127
Brushes on motors, lubrication at 10s. per car week...	6	0	0	...	·190
Wages at charging station, at £2. 10s. per car week	30	0	0	...	·952
Depreciation on buildings, hydraulic and generating plant at charging station (£6,600)	12	0	0	...	·381
Maintenance of accumulators	47	5	0	...	1·500
	£123	15	0	...	3·928

Then it must be remembered that with accumulator traction the maintenance of the roads is much cheaper, there being no electrical equipment on the line, and the capital outlay for the complete installation considerably lower than that for the other two systems. In the matter of total efficiency, accumulators again hold a great advantage. According to measurements made by Dr. Louis Bell on several American electrical tramways, the efficiency of the entire overhead system—viz., the proportion of the brake horse-power on the car motor as compared with the indicated horse-power of the engines at the generating stations—averages about 30 per cent. in everyday practice, while with accumulators, notwithstanding the increased weight of the latter, we arrive at a corresponding efficiency of over 40 per cent. It stands to reason that this must be so, as the expenditure from the cells is in direct proportion to the brake horse-power developed by the motor, while with the other systems the generating stations must be capable of furnishing the maximum current at any given moment, the average current, however, falling far short of the maximum.

We know that Mr. Sellon has mentioned the balance sheet of the Birmingham Central Tramways Company before, and we told him all we had to say with regard to this in our last letter. No doubt a copy of this as soon as it is printed will be delivered to him quite as early as to us, and set his mind at rest about the actual expenditure on the Bristol-road section. What we are prepared to work this line for under existing circumstances, and with the present plant, we must ask leave to withhold until the Board of the Birmingham Central Tramways Company have arrived at a decision on our proposal, but at what cost it could be worked by us or anybody with an entirely free hand is easily deduced from the foregoing tabulation.—Yours, etc., L. BROEKMAN, Manager,

The Epstein Electric Accumulator Company, Limited.
July 25, 1893.

'BUS-LIGHTING.

SIR,—Owing to my absence from town I have only to-day seen the comment you made in your issue of the 7th inst. on the paper I wrote for the Tramways Institute of Great Britain and Ireland. Allow me to say that I fail to reconcile *your introductory* statement—viz., "that you have narrowly watched this experiment"—with the remark that rumours contradictory to my statements are abroad. Of such anonymous assailants I cannot take any notice.

With regard to the figures which you recommend to be taken with caution, I can only say that they were most conscientiously taken from the actual results with over 150 omnibuses which perform quite publicly from and to Victoria Station, Pimlico. Far from attemping to paint matters rosy, the estimate was made with a view of accepting any challenge that members of the meeting should think fit to make. Likewise the criticism you bestowed on the price which I put down for incandescent lamps is unjustified. The first supply of incandescent lamps is covered in the outfit of £3. 10s. per 'bus. At the time the first renewals may be expected on contracts not yet entered the Ediswan patents will have expired, and you are, no doubt, aware that contracts are being freely entered by the largest electrical furnishers to supply best lamps at 1s. 6d., and less, after that date.

However, the best proof for an estimate to be *bonâ fide* is the readiness to carry it out, and I am pleased to inform you that the Bristöl Electric Safety Lamp Works, of 63, Queen Victoria-street, E.C., are prepared to contract with omnibus proprietors and tramway companies on the basis of my estimate. This firm will also undertake, at the present moment, to maintain the incandescent lamps of any number of cars at 1s. 6d. a piece, or on the figures of my estimate.

Your statement that "Mr. Bristöl has not sold any lamps to omnibus proprietors" does not testify to the carefulness of the watch you have kept. Quite the opposite is the case. The Bristöl Electric Safety Lamp Works, who hold all of Mr. Bristöl's patents, have, as far back as August, 1892, had an order from the London General Omnibus Company for 140 lamps and batteries. Being determined to make omnibus lighting by electricity a success, they tested their system privately on a small scale before they started in the streets of London. They started to light these 140 omnibuses in November and have, as far as electrical matters are concerned, not had to make the slightest alteration. That the number of 'buses lighted has been increased to 180, 153 of which run now daily, does not seem to be an unfavourable sign. The only difficulties encountered were of an administrative character. The batteries were not only irregularly returned, but were upset, left in the 'buses for several days, or lost altogether. The charging of the batteries is done by contract, and so is the maintenance of batteries and lamps as far as electrical wear and tear goes. The results seem too good to be believed by you, and I am sure Mr. Bristöl must feel your criticism more as a compliment than anything else.

You will oblige me by favouring my reply with a similarly prominent place in your valuable paper as was allotted to the attack.—Yours, etc., EDWIN FREUND.

ELECTRIC LOCOMOTION.

The first electric locomotive of any considerable size in the United States, and the first practically operative high-speed electric locomotive in the world, adapted to the steam railroad, has recently been completed at the Lynn Works of the General Electric Company, America, and will shortly be exhibited at the World's Fair. Its completion marks a distinct advance in electrical development. It is a 30 ton locomotive, designed for a normal speed of 30 miles an hour, primarily intended for operation on elevated railways, and for passenger and light-freight traffic on less important steam roads. It is of compact construction, solidly and substantially built, and runs on four 44in. wheels. Its dimensions are 10ft. 6in. long, 11ft. 6in. high, 8ft. 4in. broad, having its drawbars 2ft. 6in. from top of rail—the Manhattan elevated railway standard height. The drawbar pull is calculated at 12,000lb.

The propelling power is furnished by two electric motors of especial design and construction, each axle being provided with one motor. The motors are gearless, and are supported on spiral springs resting on the side frames of the locomotive truck. This method of suspension leaves the

wheels free to adjust themselves to the irregularities of the road-bed, and consequently the wear to both tracks and motors is diminished. The motor fields consist of massive iron castings, to which the hollow field spools are bolted. The armatures are of the iron-clad type, having each separate winding embedded in a mica-lined slot cut into the curved surface of the laminated iron armature body. The axles of the locomotive pass through the hollow shafts on which the armatures are mounted. These shafts rest in bearings of the motor frame, and are connected to the axles by universal couplings, which allow of freedom of motion in all directions. The commutators are of massive construction, and there are four sets of brushes to each commutator. The motors are controlled by means of a series parallel controller set up in the interior of the cab. This device embodies all the latest improvements made in this type of apparatus by the General Electric Company. Under test it is found that the series-parallel controller allows of a more gradual and easier starting of the electric motor, and the speed can be more delicately and instantaneously controlled than in the case of the steam locomotive.

The truck, suspended from the journal-boxes, is constructed of heavy I beams, and forms the foundation for the locomotive cab, of sheet iron, of symmetrical design, and so curved off as to diminish the atmospheric resistance as far as possible. The interior is finished in hard wood. Two sliding doors are placed at each side of the cab, and the windows are so arranged as to permit of an unobstructed view in all directions. There is ample space in the cab for the motor-man's movements, and it affords him considerably better protection than that usually vouchsafed the steam-locomotive engineer.

Train with 30 ton Electric Locomotive

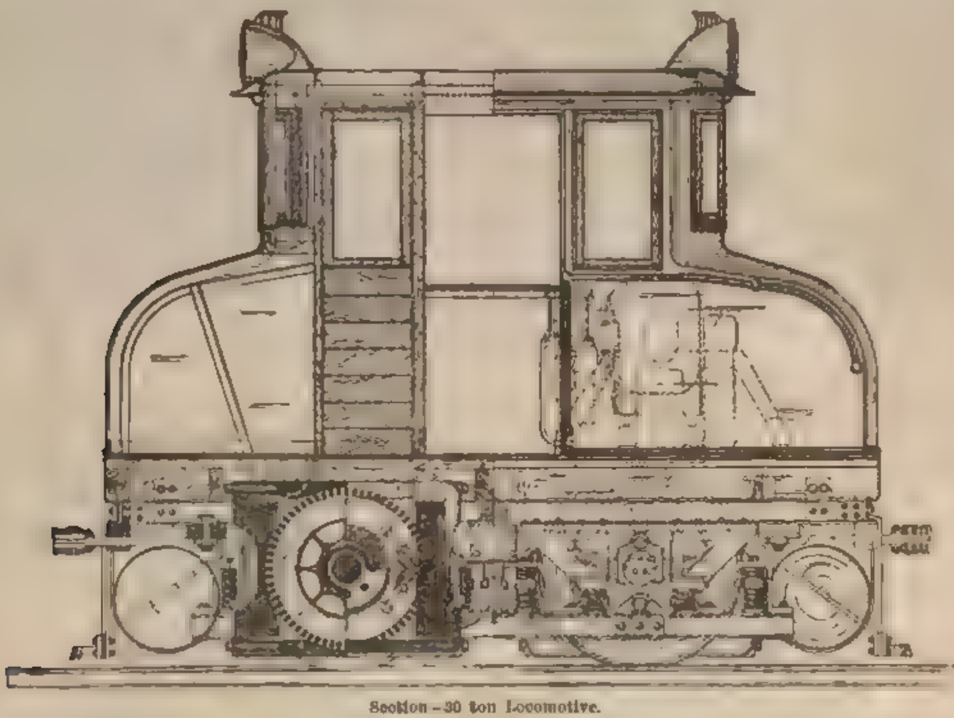
Truck—30 ton Locomotive.

The air for the brake is supplied by a special electrical air-compressor, which also operates the whistles. This air-pump has an oscillating cylinder of 6in. diameter, with a 6in. stroke, supplying 6,000 cubic inches of air per

minute at 70lb. pressure The motor is similar to the N.W.P. 2½ in general appearance, but is wound for a higher speed. The normal speed of the armature shaft is 675 revolutions, and of the crankshaft of the pump 110 revolutions. The dimensions of the air-compressor are: Length, 41in.; width, 16½in.; height, 25in. The pump motor is controlled by a special rheostat. This, by an intermediary device, is automatically regulated by the air pressure.

This locomotive has been designed for a normal speed exceeding 30 miles per hour. The use of these locomotives over very long distances is at present limited only by the cost of long lines of electric feeders, and until the problem offered by this condition is solved, restriction of its employment must necessarily exist. But for places comparatively near each other and where traffic is dense—the denser the better—the electric locomotive is peculiarly adapted, for here all the advantages of electric propulsion are available, unhampered by the extreme expense involved in long feeder lines.

The evolution of the use of the electric locomotive will probably follow along the lines dictated by expediency and favouring conditions. At first they will probably be used in elevated railroad service, and in New York, Brooklyn,



Section—30 ton Locomotive.

and Chicago alone, their advent will be hailed with a feeling of deep gratitude. They will then probably be adopted as feeders to the trunk lines, both for freight and passenger traffic, and to operate short suburban lines where a rapid efficient service is requisite. Their peculiar fitness for switching purposes will advance their use another step, and then slowly, as the different problems presented are overcome, they will invade the province of the trunk-line steam locomotive, and the millennium of railroad travel will be within the realities of life.

ON THE ELECTRIC LIGHT OF LIGHTHOUSES.*

EXPERIMENTS MADE BY THE LIGHTHOUSE DEPARTMENT OF FRANCE.

BY ANDRÉ BLONDEL.

Object of this Memoir.—The electric apparatus of lighthouses using the voltaic arc has undergone no modification for many years. The machine of De Meritens, adopted in 1881 at the lighthouse of Planier, is now in use in almost all French and foreign establishments, and gives excellent results; but of late years this machine has been severely criticised, because of its high price and antiquated type. From different quarters we have been urged to adopt more modern machines, and in particular continuous-current dynamos. With the object of improving, if possible, its installations, the Lighthouse Department of France has undertaken, on the initiative and under the direction of M. Bourdelles, inspector-general, since 1891, a series of systematic experiments which have had reference to the use of both continuous and alternate currents. The results have already been summarised in the notice on lighthouse apparatus presented by this department to the Chicago Exhibition. I propose here to explain in more detail the investigations that have been made with the two varieties of current at the lighthouse establishment, and at the same time the considerations that weigh in favour of each solution.

I shall point out first the general conditions that the machines and lamps should fulfil to ensure the safety and convenience of the service. Then I shall examine the manner in which continuous and alternate currents behave from the various points of view that have to be considered and the properties of the machines employed to produce them. Finally, I shall note the results of the comparisons made between the two systems.

This memoir will refer, then, only to the electric apparatus. The optical apparatus of electric lighthouses in France having been described in detail in the memoir above mentioned, we shall assume to be known.

General Observations on Machinery and Lamps.—The machines should be above all, of very strong construction. Their management should demand the least possible technical knowledge and the least possible attention. The speed of rotation should be moderate to reduce to the lowest point the causes of deterioration. We have decided in French lighthouses that it should not exceed 800 to 900 revolutions per minute, and for the machines of De Meritens, it has even been reduced to the half of this. Continuous lubrication must be provided. The motors may be steam, hot air, Dowson gas, petroleum, etc.*

I shall not undertake here the comparative study of these different apparatus. I shall only observe that the abandonment of the steam engine is only justified in exceptional cases, and that none of the motors suggested to replace it offer for lighthouses the same advantages of simplicity and safety. The use of the surface condenser or air condenser, which enables us to recover 75 per cent. of the water used, as also the experience obtained since 1891 in the lighthouse of Baleines, enables us to extend the application of steam even to lighthouses having a scanty supply of water.

Safety.—Besides the mechanical causes of deterioration, we have to take precautions against permanent or accidental causes arising from the current of the machine. With this object the intensity of the current must be reduced below that in ordinary use in industry, so that the rise of temperature of the windings may not exceed 20deg. C. in ordinary work, and 40deg. to 50deg.

* Paper read before the International Maritime Congress, London meeting, July, 1893.

* The hot air motor, although employed with success in certain French and other lighthouses, is only admissible in exceptional cases because of the numerous objections to which it is subject, such as irregularity of effort, lack of elasticity, etc.; and, above all, because of the excessive superintendence it requires from the attendant. The petroleum motor, which is still in use, is expensive in working, and not free from danger. Gas motors can only be used in towns having a gasworks. The solution proposed by Dr Hopkinson (Inst.C.E., December 7, 1886) has not yet been tried. The progress lately made in the employment of poor gases encourages us to believe that this method may one day be applied when the danger of intoxication by carbonic oxide has been overcome.

on short circuit. This result may be obtained without sensible diminution of the efficiency, while certainly prolonging the life of the dynamo. The deterioration of the commutators by sparks need only be feared in continuous current dynamos. The progress obtained in this direction relieves us now from any anxiety on this score. The accidental causes of deterioration to be guarded against all result from too sudden alterations in the current, consisting either in abrupt interruptions, or in short circuiting. In every case we ought to have at least a second generating unit in reserve ready for immediate use if the first has to be cut out of the circuit.

Gradation of Light, according to the Degree of Transparency of the Atmosphere.—In a certain number of old lighthouses two grades only are used, a simple and a double light—one, as the term implies, corresponding to double the intensity of current of the other. In French lighthouses of the old type these intensities are respectively 50 and 100 amperes. In the English lighthouse of St. Catherine they are 175 and 350 amperes. They are obtained by supplying the lamp either with one of De Meritens's machines, type G or L, or with two coupled in parallel circuit. But the gradation so obtained is imperfect, because the reduction of range due to atmospheric absorption varies in a much greater ratio than that of 2 to 1, when the weather changes from moderately clear to foggy. In average weather—that is to say, for about 20 per cent. of the year on the French coast of the Channel and the ocean—a current of 25 amperes is more than sufficient with bi-focal apparatus to enable the geographical range to be attained, and even surpassed. In the flashing apparatus, *feux éclairs*, an illumination is realised which reaches to 85 miles, whilst in foggy weather a double intensity corresponding to a current of 100 amperes only reaches 26 miles. In these conditions it is necessary that the intensity of the current should vary at least from 1 to 4, and that the weaker currents, which are the most used, should be obtained with suitable efficiency.

In French lighthouses the two extreme currents are 25 and 100 amperes. Many combinations may be made to obtain intermediate gradations.

1. Two machines, one supplying the minimum current, and the other, more powerful, supplying the maximum, each at their maximum efficiency. The only inconvenience of this method is that in case of breakdown of the large machine the small one does not constitute a sufficient reserve and that a third is necessary. Besides, the efficiency of the mechanical motor diminishes in general so quickly with the power that the advantage gained in electrical efficiency is rendered nugatory.

2. A single machine capable of furnishing, as desired, the various currents, and duplicated with a second similar unit as reserve. In this case the efficiency is necessarily much smaller with the smaller current.

3. A machine capable of supplying the mean current, combined with a secondary battery which, charged during the day, may be discharged at night alone during clear weather, and in parallel with the machine during foggy weather. This solution, suggested by different engineers,* seems to render possible a reduction of the staff, seeing that the maximum power is necessary during only two months of the year at most. But it is not so, and in any case the advantage so gained would be neutralised by the additional cost of the establishment and maintenance of a set of accumulators called on to act as much as 16 hours at a stretch, with a current of 15 amperes. The battery would be more cumbersome than a dynamo, and would require attention that can scarcely be expected from ordinary lighthouse attendants. Lastly, the efficiency would be more reduced owing to the absolute necessity in which we are placed of interpolating a considerable resistance, as we shall see latter, in a continuous-current arc circuit fed by a battery. Accumulators are not then applicable to the supply of an electric arc light for lighthouses with the arrangements in use at the present time. It by no means follows that they may not some day be utilised in a different manner.

4. Two machines, each having currents of 25 to 50 amperes, and arranged so as to be coupled in parallel in order to provide a current of 100 amperes.

This solution, which has been adopted for the service of French lighthouses, appears the simplest, the most favourable to symmetry in the installation, and the most economical from every point of view. It enables us to obtain a satisfactory efficiency with the 25 amperes current, and ensures a sufficient reserve in case of accident.

Arc Lamps.—These lamps, as we know, have their mechanism in the lower part, and rest directly on the platform, Fig. 9, of the optical apparatus. Its principal function is to constantly bring together the carbons as they are consumed. Some of them have a striking arrangement which automatically separates the carbons to start the arc. But none of them in ordinary working can increase the distance of the carbons if they have accidentally come too close to each other. In that respect an improvement might perhaps be introduced, but we can avoid the cause of too near an approach by suppressing, as we shall see later, the variations of the current.

The lamps for alternate currents, Fig. 9, almost the only ones at present used, all belong to the original Serrin type, or to that type modified in certain points of detail by MM. Berjot, Le Baron, Cholina, etc. The movement of approach, which is made under the action of the weight of the upper carbon holder, is governed by clockwork, with an escapement put in play by an electromagnet when the distance becomes too great.

The necessity of reducing the heating effect on the magnet and the change of attractive force that arises with the change of current has led for some time to the abandonment of the practice of putting the electromagnet in series with the principal current. In the new French lighthouses, we send, whatever the main current may be, the current of half of one of the machines of De Meritens through the electromagnet; the remainder goes directly to the lower carbon by another cable. This method, which requires three cables complicates the installation and the construction of the switchboard, although care may be taken to connect all the commutators of this board so as to enable the change of current to be made by one operation. It is more natural to employ, as in the lamps of Le Baron, an electromagnet placed in a shunt and wound with fine wire. The number of conductors is reduced to two, and there is no further need to split up the machine circuit.

The same type of regulator might also well be applied to continuous currents. Messrs. Sautter and Harlé have preferred to adopt for the experimental lamps of the lighthouse of La Hève a type analogous to that of the projectors, Fig. 2, in which the approach of the carbons is produced by a screw passing through the two carbon holders, and operated by an electromotor through a ratchet. The latter receives a shunt from the principal current through a relay controlled by a small electromagnet placed in shunt across the terminals of the lamp. Each movement of the screw is accompanied by a similar improvement of rotation of the socket of the lower carbon holder so as to regulate the shape of the carbons. But this movement is too slow to produce a favourable result. The principal advantage of this lamp consists in the employment of the solenoid, S, placed around the lower carbon, of which the purpose will be later explained. With the present lamp the regulation of the arc so that it may occupy the focus of the apparatus is effected, as is well known, by the aid of a screw that raises or lowers the two carbons simultaneously. The attendant constantly moves the screw so as to bring the image of the arc or of one of the carbons to a mark traced on the table. There would evidently be an advantage in producing this movement automatically, but the attempts made in this direction have not been sufficiently satisfactory to lead us to pursue them further. An automatic system would also have the disadvantage of not requiring the attention of the attendant, which it is as well to stimulate.

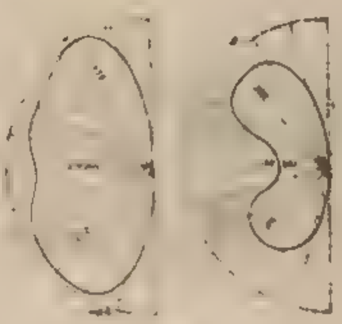


FIG. 8.

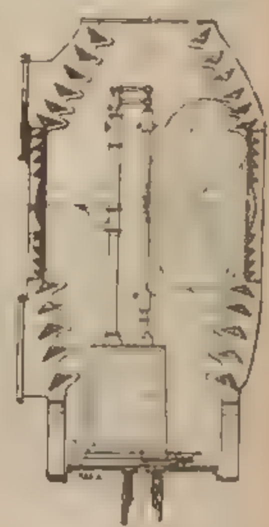

FIG. 9.

Influence of the Properties of the Dynamo on the Sensitiveness of Regulation of the Lamp.—The lamp consuming the whole of the current, the manner in which the pressure varies as a function of the current depends only on the construction of the machine, and the characteristic curve of supply at the lamp terminals only differs from the external characteristic of the dynamo by the small quantity representing the loss of pressure in the conductors. The method of regulation of the lamps (whether in series or in shunt) must therefore be chosen according to the form of the characteristic. If the latter has little slope (we shall see later that it is necessary for it to descend in the direction corresponding to a rising current) the amperes will vary more quickly, comparatively, than the volts for a given variation of distance between the carbons. The most sensitive mode of regulation will be then that in series; on the contrary, if the curve has a considerable slope regulation by a shunt should be preferred. Finally, if the characteristic is inclined at 45deg., which we shall see is practically the case with the dynamos of De Meritens, the two modes of regulation are equivalent, and, consequently, we ought to adopt the simplest—that is to say, regulation by a shunt.*

Reactions Produced on the Dynamo and the Motor by Variations in the Resistance of the Arc.—The electric arc being the only apparatus utilising the current, every variation of its resistance, and thus of the energy that it consumes, will be felt by the dynamo and the motor in the form of variation of speed, which, again, will modify the *régime* of the arc. These reciprocal reactions cause an oscillatory condition, resulting in periodical

* Inst.C.E., December 7, 1886.

* Differential regulation would give double the sensibility, but the complication it would involve in the distribution of the circuits renders it undesirable.

vibrations of the light that may end in its extinction or in a breakdown of the mechanism.

To avoid these difficulties, it is necessary to furnish the motors with a sufficiently sensitive governor, and to get rid of the oscillations by choosing the constants of the dynamos so that at about the usual current the demand it makes on the motor for power increases with the intensity,* or better, passes through a maximum,† an arrangement which is easily attainable for alternators.

EMPLOYMENT OF CONTINUOUS CURRENTS.

Section I. —Properties and Useful Effect of the Arc with Continuous Currents.

Constitution and Intrinsic Brightness.—It appears to be established that the arc consists of a current of carbon reduced to a state of vapour at the surface of the positive pole, which assumes

FIG. 2.

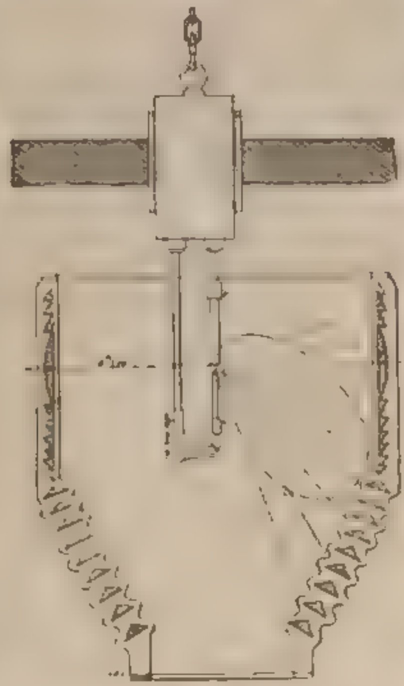

FIG. 3.

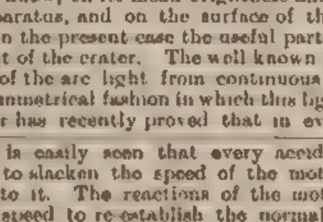
the form of a crater; owing to this circumstance, the positive pole constitutes the most brilliant part of the electric arc. It is estimated that it furnishes more than 85 per cent. of the light produced, while the negative carbon gives less than 10 per cent., and the arc properly so called less than 5 per cent. The temperature of volatilisation of carbon being a physical constant, the temperature of the crater must be invariable for a given carbon, and consequently also its intrinsic brightness—that is to say, per unit of surface. The experiments of Messrs. Abney, Rosetti, and Violle, etc., have shown that this is correct. But this law is only applicable to the maximum brightness; in fact, this maximum is only produced on a variable portion of the crater, and the mean brightness of the crater may vary within wide limits‡—that is to say, the total light that it emits divided by its total surface.



Distribution of the Light.—The power of a pencil of light produced by a luminous source placed in a given apparatus only depends, as we know, on its mean brightness and the geometrical form of the apparatus, and on the surface of the latter usefully illuminated. In the present case the useful parts are those which receive the light of the crater. The well known form of the curve of distribution of the arc light from continuous currents, Fig 8, shows the unsymmetrical fashion in which this light is distributed; and Mr. Trotter has recently proved that in every direction the quantity received is nearly proportional to the portion of the visible surface of the crater. It thus appears that above the horizontal plane through the edges of the crater the electric arc is of no great service.

Arrangement of the Carbons.—In placing in our present apparatus the positive carbon above the negative, as was done in the first applications, notably at the Lizard (England), the most important part of the apparatus was not made use of. Sir James Douglass proposed, in order to overcome this difficulty, to place one of the carbons eccentrically, so as to produce an oblique crater similar to that of projectors. But this arrangement, which only illuminates the apparatus over a very limited part, is unsuitable for lighthouses in the generality of cases.* It has then been attempted to place the positive carbon below and the negative above; but a further difficulty is then met with. The arc which with the crater above finds itself, so to speak, kept in place by the latter, now begins to travel round the edges, is uncertain, and is easily extinguished. This difficulty, not important with small lamps, becomes so serious with currents of more than 50 amperes, that it has hitherto completely hindered the employment of continuous currents. An attempt made in this direction at May Island (Scotland) in 1886 proved disappointing.

Messrs. Sautter, Harlé, and Co. have recently overcome the difficulty by a very ingenious application of electro-dynamic action; for this purpose they arranged concentrically to the lower carbon, Fig. 2, and as near as possible to the arc a solenoid formed of several turns of thick copper wire traversed by a shunt from the current of the lamp and protected by a refractory plate; the arc behaving like a fluid conducting body begins to turn around its own axis with a very rapid movement, as was shown by an instantaneous photographic record,† and immediately obtains, in virtue of its gyration, a great stability. The regularity in the shape of the carbons is favoured in some measure by the slow movement of rotation given as described above to the lower carbon. It is with a Sautter Harlé lamp of this system that the experiments have been made at the lighthouse establishment, and will be pursued at the lighthouse of La Heve. It might be well to adopt it for continuous currents, if we had to preserve the present forms of lamps and apparatus. In this case all the part of the optical apparatus below the focal plane not seeing the crater ought to have as its focus the point of the negative carbon. It would even be better to suppress it completely, and give to the cupola a larger development in diameter and in height, as was done for the apparatus of the Isle of May where the only mistake was in replacing by catadioptric rings the upper half of the dioptric drum.‡

Useful Effect obtained with Different Currents.—With arcs which are geometrically similar—that is to say, in which the proportion between the distance apart of the carbons, the diameter of the carbons, and the square root of the intensity remains the same—the occultations of the crater by the negative carbon have the same relative value. We must, then, always obtain the same optical effect at a great distance, and there would be no advantage in employing arcs of great intensity. In practice, this somewhat hasty conclusion is contradicted by experience, as is shown by the following table, in which are collected results obtained from experiments made with similar continuous current arcs.

Apparatus.	Diameter of carbons. Upper	Diameter of carbons. Lower	Intensity of current in amperes.	Pressure at the terminus in volts.	Power expended in watts.	Mean minimum power in carcels.	Luminous efficiency per watt in carcels.
	mms.	mms.					
Bi focal (type 1888) ...	10	13	25	50	1 250	411,000	329
,,	18	22	75	53	3,975	661 800	167
,,	18	25	90	52	4,680	900,000	192
Feu-éclair bi focal apparatus of La Heve ...	13	13	25	53	1 325	637,000	481
,,	18	21	47	55	2 585	916,000	354
,,	21	23	98	50	4 900	1,300,000	265
,,	18	23	94	57	5,358	1,781,000	332

This apparent contradiction might be explained by the small extent of the luminous surface compared to the inevitable aberra-

* In fact, it is easily seen that every accidental increase of intensity tends to slacken the speed of the motor, every diminution to accelerate it. The reactions of the motor tend, then, in any change of speed to re-establish the normal *regime*. On the contrary, if the power decrease, the variations of speed of the motor would reinforce the departures from the normal condition which gives rise to them.

† In this case the variations of power produced by a departure from the ordinary state are insensible.

‡ In the experiments made in 1878 at Chatham by R.E. officers, it was found that the mean brightness may vary from 26,000 to 76,000 candles per square inch. I have also observed similar variations.

* Except, of course, in cases where a projector might actually be used.

† *Lumiere Electrique*, vol. xlii., p. 60.

‡ Under these circumstances it might perhaps be advantageous in certain respects to turn round the half apparatus, giving it the arrangement shown by Fig 3. We might then replace the ordinary lamp by a lamp suspended to the upper part and analogous, save as regards power, to those employed in public lighting, in adopting for carrying the lower carbon a single rod placed on the land side, the lamp might be put in a case fixed to a small footbridge accessible to the attendant, and its replacing could be effected almost instantaneously, without any need of stopping the apparatus of rotation. Thanks to the employment of a positive carbon above, we should obtain a suitable condition of the arc more easily than now. Lastly, in giving to the apparatus a diameter of one millimetre in place of 0 60 millimetre, for example, we should amply compensate for the loss of useful surface due to the suppression of a part of the drum and of the ring, and should restore the horizontal divergence to a value nearly that which it has at present.

tions.* Further, we must not forget that when the maximum brightness is constant, the mean brightness of the useful incandescent part may be variable within certain limits, as was said above.

Influence of the Diameter of the Carbons.—Even admitting the constancy of the brightness, there is an advantage with regard to occultations in fixing the diameter as much as possible. We are limited only by the heating of the carbons, which increases their combustion and loss of energy, and may injure the sockets. The current given in the last line of the preceding table is for this reason inadmissible. If we calculate from the experiments of the table dimensions applicable to different currents, taking into account the laws of similarity, the following figures will be arrived at as maxima in the case of bare carbons:

Intensity of the current in amperes.	Upper carbon. Diameter in mms.	Upper carbon. Section in sq. mms.	Upper carbon. Intensity of current per sq. mm.	Lower carbon. Diameter in sq. mms.	Lower carbon. Section in sq. mms.	Lower carbon. Intensity of current in sq. mms.	Distance between carbons to be adopted in mms.
25	11 5	104	0·23	13	133	0·19	4 to 5
50	16	201	0·25	18	254	0·20	6
100	21	346	0·29	23	449	0·22	8

Separation of the Carbons.—The minimum distance apart which enables us to obtain from arcs of 25 amperes and upwards a light free from hissing is from 4mm. to 5mm., corresponding to a pressure of 45 volts at the arc and about 50 volts at the lamp terminals. There is an advantage with regard to optical efficiency in increasing the distance a little until the crater is completely free without passing the limit at which the arc becomes unstable and produces too much flame.

The preceding table indicates the data which seem to me the most favourable according to experiments and to the geometrical form of the arc.

Nature of the Carbons.—When the carbons are properly purified, as is generally the case for those in use in industry, which do not contain more than 2 to 3 per cent. of ash, the maximum intrinsic brightness remains practically constant, whatever is the nature of the carbons. That, at least, is the result I have obtained from a great number of comparisons made with the pyrophotometer.† But there is an advantage with regard to the occultations in reducing the diameter by employing the hardest possible carbons, which, owing to their great conductivity, can carry the most intense current without heating. The carbons of M. Carre, saturated with carbon by being many times successively soaked in syrup and baked, are successfully employed. They carry very well the current of 0·02 to 0·03 amperes per square millimetre given in the preceding table. To give to the arc a suitable stability we should add a core, but it should not be made too good a conductor, as otherwise the mean brightness might be diminished.‡

Conditions of Stability of the Arc.—The steadiness, independently of all conditions above treated relating to the mechanism of the lamps demands a special condition well known to electricians. It is necessary that the characteristic curve of supply at the terminals of the lamp, such as the curve M N, Fig. 4, for example, should be a falling curve, and have a sufficient slope.*

The engineers of the French navy have fixed the following slopes as necessary to the steadiness of a projector are regulated by hand†:

Arc of 45 amperes	43 volts.	
„ 65 „	45 „	Slope of 0·50 to 0·60
„ 75 „	48 „	„ 0·45 „ 0·55
„ 95 „	50 „	„ 0·35 „ 0·45

With automatic lamps in lighthouses, lower values may be adopted. It seems to be enough to have an E.M.F. of about 70 volts for one machine of constant potential, which corresponds to the following slopes:

Arc of 25 amperes.	V. at terminals = 50	V. at arc = 45	Slope = 1
„ 50 „	„ = 52	„ = 47	„ = 0·46
„ 100 „	„ = 55	„ = 50	„ = 0·40

This slope may be obtained either by the actual form of the external characteristic, or by the aid of an interpolated resistance. The wires which connect the machine to the lamp contribute to this effect; in a lighthouse 60m. high, with a connection of 20m. for example, a cable of 37 square millimetres in section, capable of transmitting 100 amperes, represents a resistance of about of 0·08 ohm, and absorbs nearly eight volts (without counting the resistance of the joints) with this current of 100 amperes.

(*To be continued.*)

* In consequence, in fact, of defects of construction in the refracting surface, the rays which are called "focal"—that is to say those which after refraction form the useful part of the pencil—do not all pass strictly through the geometrical focus of the apparatus. Those only are utilised which meet the incandescent part of the crater, and the number of them must evidently increase with the dimensions of the latter, until it becomes so great as to enclose all the focal rays. This view is justified by the important difference noticed between the actual divergence of the apparatus and the theoretical divergence calculated. For example, the apparatus of La Hève has furnished the following results with alternate currents:

Diameter of carbons.	Intensity.	Distance apart.	Divergence. Calculated.	Divergence. Measured.
10mm.	25 amp.	5mm.	0° 52′	1° 2′
23 „	95 „	5 „	1° 45	2° 15′

† V. *Bulletin de la Société Internationale des Electriciens*, March, 1893.

‡ The part played by the core may be considerable in respect of the pressure and the brightness, the same carbons at the same distance apart requiring differences of potential of 40 to 50 volts, according as the central part is composed of material more or less friable, conducting, and plentiful. This difference arises from the artificial increase of conductivity produced by the continued transference of these matters in the arc. This conductivity permits a part of the current to pass from one pole to the other without volatilising a corresponding quantity of carbon. In consequence of this action, although the maximum of brightness of the crater remains constant, the surface raised to this degree of incandescence may be found seriously reduced. This may be easily ascertained by considering a projection of the crater. We may thus understand how it is that soft core carbons tend to give a mean brightness inferior to that of homogeneous carbons or those with a hard core, and have always given inferior results in efficiency in lighthouse apparatus.

* The explanation of this condition has not been agreed upon. I have given one founded on a consideration of the characteristic of the arc which seems to me the most natural (*Lumière Electrique*, vol. xlii., p. 62).

† "Memoir on the Installations of Electric Lighting on Board Ships of War," by M. Dollard, naval engineer, 1889.

COMPANIES' REPORTS.

CITY AND SOUTH LONDON RAILWAY COMPANY.

Directors: Charles Grey Mott, Esq. (chairman), Harrow Weald Lodge, Stanmore; Charles Seymour Grenfell, Esq., Elibank, Taplow; Sampson Hanbury, Esq., Wyvenhoe Park, near Colchester; S. Barclay Heward, Esq., 96, Ashley-gardens, Westminster; Edwin Tate, Esq., 21, Mincing-lane, London, E.C.

Report of the Directors for the half year ending June 30, 1893, to be submitted to the half yearly ordinary general meeting of the Company to be held at Winchester House, Old Broad-street, on Tuesday, August 1, 1893, at 12 noon.

The receipts from all sources for the past half year have amounted to £23,159 6s. 3d., and the cost of working has been £14,964 0s. 6d., leaving a profit of £8,195 5s. 9d. Inclusive of the balance brought forward from December 31 last, the net revenue account shows an aggregate total of £9,073 12s. 10d. After making provision for the debenture and debenture stock interest, amounting to £4,110. 13s. 10d., a balance remains available for dividend of £4,962 19s. Out of this sum your Directors recommend the full dividend of 5 per cent. per annum be paid on the preference shares, and that a dividend at the rate of ¾ per cent. per annum be paid upon the consolidated ordinary stock, leaving a balance of £898 to be carried forward to the next account. The number of passengers conveyed during the six month ended June 30, 1893, exclusive of season-ticket holders, was 3,146,656, showing an increase over the corresponding period of the previous year of 333,494. This increased traffic has been carried with immunity from any accident whatever, and the train service has been worked with unfailing regularity. Your Directors regret that the amount paid for local rates and taxes continues to show an increase. The following table shows the number of passengers, exclusive of season ticket holders, carried since the opening of the railway in each half year:

Half year ended	Number of passengers.	Receipts (including season tickets).
Dec. 31, 1890 11 days about	165,000	£1,568 3 9
June 30, 1891	2,412,342	19,403 6 9
Dec. 31, 1891	2,719,055	19,798 16 6
June 30, 1892	2,813,162	20,931 4 2
Dec. 31, 1892	3,217,602	22,002 17 5
June 30, 1893	3,146,656	22,458 6 9
Total since opening of line	14,503,818	£106,162 15 4

The engineer certifies that the locomotives, rolling stock, generating plant, permanent way, and station buildings have been efficiently maintained in good working condition. The new sidings at the Stockwell terminus are nearly completed, and will shortly be brought into use. The working of the traffic will be greatly facilitated by this much needed accommodation. To meet the requirements of the increasing traffic, some additional rolling stock is now in course of construction. The Bill for the extension to Islington and other purposes has passed the House of Commons and now awaits the committee of the House of Lords, where it is unopposed. This Bill includes also the extension of time for the purchase of lands and construction of works under the Act of 1890 (Clapham Extension). During the half year £3,800 of terminable 5 per cent. debenture mortgage bonds have been paid off and replaced by 4 per cent. perpetual debenture stock. In order to provide at once some additional accommodation for passengers at the entrance to the King William-street Station, the lease of the adjoining premises in Arthur-street East has been acquired on favourable terms, and the requisite alterations will shortly be commenced.

CHILI TELEPHONE COMPANY, LIMITED.

Directors: Colonel R. Raynsford Jackson, 31, Harrington gardens South Kensington S W (chairman; Thomas Greenwood, Esq, Forest Lodge, Keston, Kent (vice chairman); Hon F. Ernest Allsopp, Hadsor, Droitwich; Frank W Jones, Esq, Morravale, Hampton Wick, Middlesex

Report of the Directors to be presented to the shareholders at the ordinary general meeting to be held at Winchester House Old Broad street, E C, on Wednesday, August 2, at 12 30 p.m

The business of the Company during the past year has shown a satisfactory improvement in dollars, but has been less profitable in sterling than that of previous years. This result is due to the depreciation in the sterling value of the dollar, which has fallen from 19d. on March 31, 1892, to 15d. on the same day this year.

The income in dollars from subscribers and other sources for the year 1892 93 was	$448,661
For the previous year	378,830
Showing an increase of	$69,831
The maintenance operating, and general expenses in Chili were, in 1891 92	$271,180
„ 1892 93	263,988
A reduction of	$7,192
The increase of income having been	$69,831
And the diminution of expenses	7,192
The total result was more favourable than in 1891 92 by	$77 023

The outgoings in 1891 92 were 71 6 per cent upon the gross revenue, but in 1892 93 they fell to 58 8 per cent, a reduction of nearly 13 per cent This satisfactory rate of profit was in dollars only; the unfavourable rates of exchange reduced the available income in sterling very considerably. The net profit on working was—

In 1892 3, at 18d. the $	£13,850
In 1891 2, at 19½d. the $	8,746
Increase, notwithstanding the fall of 1½ in the average value of the dollar	£5,104
But the loss on the sterling value of the liquid assets on March 31, comparing the same two years, was 4d. per $, and amounted to	4,750
Therefore the net increase in sterling was only	£354

The increase in the outgoings in England—including the interest on debentures—was £1,027, so that the net available sum for the year is less by £673 than in the previous year The profits having been used for capital purposes cannot be divided, and consequently the balance has been carried to a reserve account. As the tariff rates are paid in the paper dollar—now so seriously depreciated—the Board has found it imperative to increase those rates This has been done in some centres, and will be done in others A reduction in the number of subscribers may therefore be expected but the income will doubtless be maintained throughout, and probably considerably augmented when the irritation generally created by changes of this kind may exhaust itself. It will be observed that the capital outlay for the past year is £16,701 being £2 000 less than the previous year. This sum has been expended on the completion of the construction of the new trunk lines, and the usual preparation for connecting additional subscribers with the exchanges; the latter is now the only kind of expenditure on capital account. The 4,000 shares offered to the proprietors were all taken by them, and have all been paid for in full In accordance with the articles of association, Messrs. Allsopp and Greenwood retire from the Board of Directors, and being eligible offer themselves for re-election. The auditor Mr. Thomas A. Welton, also retires, and offers himself for re-election.

CROMPTON AND CO., LIMITED.

Directors: Viscount Emlyn (chairman); Rookes Evelyn Bell Crompton, Esq., and John Francis Albright, Esq (managing directors); H. H. J. W. Drummond, Esq.; Bernard Gibson, Esq; Carleton F. Tufnell, Esq.

Fifth report of the Directors, to be presented at the annual general meeting of the shareholders at the City Terminus Hotel Cannon street, in the city of London, on Monday, July 31, 1893, at 3 p.m.

The Directors herewith present to the shareholders the fifth annual statement of accounts made up to the 31st March last. From this it will be seen that although the gross profits show an increase upon the figures of the preceding year, the net results have been adversely affected by unusual and unforeseen expenditure In January last the boilers at the Chelmsford works suddenly gave out, and had to be replaced by others, and the year's working has had to bear a large share of the cost of this renewal and of the temporary arrangements necessitated thereby. It is highly improbable that any similar abnormal expenditure will recur in future years, but the Directors feel confident the shareholders will agree with them that it is right it should be charged to the year's account, even at the cost of a reduced dividend The orders in hand continue good, and negotiations for several important contracts are approaching completion. The net profits for the year amount to £11,953. 7s. 4d., and after providing for debenture interest and payments set out in the revenue accounts, and, deducting the interim dividends paid, there remains, with the £98. 10s. 2d. brought forward from last year, a balance available for dividend of £3,019. 12s. 8d. The Directors propose, after setting aside £750 as a provision for doubtful debts and contingencies, to declare a preference dividend of 2s 6d per share, making with the interim dividend already paid 6 per cent. per annum on the preference shares, to provide which the sum of £800 will be taken from the reserve fund. In accordance with the articles of association Mr. H H J. W. Drummond retires from the board of directors by rotation, but offers himself for re election. The auditors, Messrs. J. H Duncan and Co., also offer themselves for re-election.

Statement of Liabilities and Assets at March 31.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED.

Directors: James Staats Forbes, Esq (chairman); Major Samuel Flood Page (deputy chairman), the Earl of Lichfield; Shelford Bidwell, Esq., F R S; Ernest Villiers, Esq.

Tenth annual report of the Directors to be presented to the shareholders at the annual meeting to be held at the Cannon-street Hotel, E.C, on Friday, July 28 at 1 p m.

The business of the Company has resulted in a credit balance of £86,642. 5s. 1d. Of this, £20,632. 19s. 5d was distributed on March 14 last as an interim payment on the A shares. The Directors recommend a further distribution of £22,976. 1s. 5d. on the A shares; and the whole of the cumulative preference on

the A shares having now been paid, of £3,534 12s. on the B shares, the whole to be distributed in accordance with the provisions of Clause 87 of the articles of association. This will absorb £47 143 12s. 10d., leaving £39,498 12s. 3d., which the Directors have carried to the reserve fund, in accordance with Clause 89 of the articles of association. This will make the present distribution:

	Per share.
On the ordinary A shares	4s. 1d.
On the fully paid A shares allotted to the Swan United Company	5s. 1d.
On the fully-paid A shares allotted to the Edison Company	6s. 8½d.
On the B shares (fully paid)	3s. 0d.

All free of income tax.

The Directors are developing the manufacturing branch of the business, and are making and supplying electrical instruments, fittings, and electrical appliances. They have reopened the factory at Newcastle, and have opened depots for the sale of lamps and fittings in the principal towns in the provinces. Major Flood Page and Mr. Bidwell, F.R.S., retire by rotation from the Board, and offer themselves for re-election. Messrs. Welton, Jones, and Co., the auditors, offer themselves for re-election.

BUSINESS NOTES.

Brindisi.—The electric lighting of this town is to be extended.

Dieppe.—It is proposed to establish an electric tramway between Dieppe and Arques.

Canada.—Transmission of power plants are being rapidly extended in Canada.

Waterloo and City Railway Bill.—In the House of Commons on Tuesday, the Lords' amendments to this Bill were considered.

Lighting in Bolton.—The Gas Committee of the Corporation have decided to commence the laying of electric mains in the various streets.

Electric Construction Corporation.—The registered address of this Company is now Queen street-chambers, Queen street, Cheapside, London, E.C.

Edinburgh Electric Supply Company.—According to the resolution of June 28, and its confirmation on July 18, this Company will be wound up voluntarily.

Chiswick.—The Chiswick Local Board have affixed their seal to the deed of transfer and lease to the Bourne and Grant Electricity Supply Company, Limited, as to the provision of electric lighting in Chiswick.

Interest on Stock.—The interest on the 4 per cent. mortgage debenture stock of the Eastern Extension, Australasia and China Telegraph Company for the half year ended 31st July inst. will be paid by warrant on 1st August next.

Leeds.—The following tenders have been accepted for the extension works at Leeds for the Yorkshire House to House Electricity Company: Builders' works, W. Nicholson and Son, Hunslet; engines, dynamos, etc., J. Fowler and Co.

City Hall Lighting.—Among the many contracts obtained by Messrs. Drake and Gorham, within the last few days may be mentioned the rewiring and fitting of the hall and offices of the Company of Leather Sellers, in St. Helen's place.

Contracts Open.—As will be seen by our advertisement columns (p. xvi.), the St. Pancras Vestry invite tenders for building a chimney shaft and making a subway, and for supply of batteries, cables, copper strip, iron pipes, boilers, engines, and dynamos.

Bournemouth.—The Town Council have received a letter from the Bournemouth, etc., Electric Supply Company, in reply to the complaint as to the mode in which their works were carried out, stating that in all cases every care was taken in carrying out their works.

Crompton and Co.—The balance sheet of this Company shows a gross profit of £40 443 0s. 5d., and a net profit of £11,953. 7s. 4d. Last year the gross profit was £36,675. 6s. 7d., and the net profit £16,068. 16s. 11d., as will be seen from the balance sheet given in our issue of July 29, 1892.

Boy Messengers.—The District Messenger Company of Paris, Limited, is being formed with a capital of £200,000, divided into 112,000 7 per cent. preference shares of £1 each, taking precedence as to revenue and capital, 80,000 ordinary shares of £1 each, and 400 founders' shares of £20 each.

City and South London Railway Company.—The receipts for the week ending July 23 were £761, against £788 for the same period last year, or a decrease of £27. The total receipts for the second half year of 1893 show an increase of £317 over those for the corresponding period of 1892.

Guildford.—At the last meeting of the Rural Sanitary Authority it was mentioned that the Holloway Electricity Supply Company, Limited, had written that they intended making application for a provisional order to include the lighting of the two extra municipal portions of Guildford.

Direct Spanish Telegraph Company.—The Board have decided, subject to audit, to recommend the payment of the dividend at the rate of 10 per cent. per annum on the preference shares, and a dividend at the rate of 4 per cent. per annum, free of income tax, on the ordinary shares, both for the half year ended June 30 last.

Notice of Dividend.—We have received notice that the directors of the Westminster Electric Supply Corporation, Limited, have declared an interim dividend for the half year ending June 30 last at the rate of 3 per cent. per annum, payable on September 18 next to all shareholders whose names are on the register on July 26.

Charing Cross and Strand Corporation.—The Directors of the Charing Cross and Strand Electricity Supply Corporation, Limited, at a Board meeting held on Thursday, July 20, decided to declare an interim dividend at the rate of 5 per cent. per annum on the ordinary shares (30,000 of £5 each). This will be paid on August 15, 1893.

Lighting of the Western Coast.—A movement is about to be set on foot for furthering the proposal made at a meeting of the Cardiff Chamber of Commerce by Captain Pomeroy with respect to the improved lighting of the coasts from Pembrokeshire, on the one hand, and Devonshire on the other, up to the mouth of the Severn.

Wrexham.—At the monthly meeting of the Town Council it was resolved to negotiate terms for taking over the provisional order of the Wrexham and District Electric Supply Company, Limited, but not to include the adoption or taking over of a provisional contract for works of supply either with the Brush Electric or any other company.

Doulton Electric Conduits.—Messrs. Doulton and Co., of Lambeth, request us to announce that their patent conduit for underground electric mains, together with a selection of pottery

for electrical purposes, which has been exhibited at their Lambeth showrooms during this week, will remain on view to engineers, on presentation of card, until August 5.

Manchester.—On Wednesday, at a meeting of the General Purposes Committee of the Manchester City Council, the question of telephones and traction was discussed. It was decided that in view of the decision of the Joint Committee, the municipal corporations must consider what action to take in regard to any Bills promoted to further electric traction.

Swansea.—The Property and General Purposes Committee of the Swansea County Council, at a meeting last week, reported that letters, which were read, had been received from the solicitors of Messrs. Crompton and Co., Limited and Messrs. Hannford and Wills, respecting electric lighting in the borough of Swansea. The letters were referred for report to a sub committee.

City Authorities and the Telephone.—The City Commission of Sewers decided on Tuesday, in view of the concessions asked for by the City of London Electric Lighting Company to lay telephone wires in the electric light mains, to grant the request on condition that telephones with double wires be supplied to the citizens at a cost of not more than £8 per annum. The charge at present is £20.

Oriental Telephone Company.—The directors of this Company have resolved to recommend to the shareholders, subject to final audit of the accounts, a dividend for the year ending 31st December last at the rate of 2½ per cent. on the entire paid up capital of the Company. The dividend being payable only to holders of the ordinary shares is equivalent to £3 12s 2d per cent. on each share of 11s. paid—the same rate as paid for the previous year.

Derby.—The Derby Corporation are laying down cables in the principal thoroughfares for lighting them by electricity. The generating station is erected on the site of Lombe's silk mill. At the present moment it has been arranged to erect 46 pillars and arc lamps in the town, and already the mains have been laid a considerable distance from the works. Messrs. Bramwell and Harris are the engineers, and Mr Vernon, of Derby, the contractor.

Edinburgh Tramways.—At the last meeting of the Lord Provost's Committee of Edinburgh Town Council, a letter was submitted from the Caledonian Electric Supply Company, intimating their intention to apply to Parliament for powers to construct electric apparatus to run electric cars between Coltbridge and Corstorphine. The committee agreed to recommend the magistrates and Council to refuse to give their consent to any such scheme.

Johnson and Phillips.—Messrs. Johnson and Phillips, with deep regret, announce the death of Mr. Samuel E. Phillips, which took place on the 22nd inst. As is well known to most of their friends Mr. Phillips had been in failing health for some years, and had of late taken no active part in the business of the firm. Mr. W. Claude Johnson henceforth becomes sole proprietor of the works and business, which will be carried on upon exactly the same lines as heretofore.

Windsor.—At the monthly meeting last week of the Town Council, some letters were read from the Board of Trade with reference to the Windsor Electric Lighting Company, to the effect that the company had failed to satisfy the Board of Trade that they were in a position to carry out the provisions of the order granted in 1890. The Council decided to appoint a committee from the authority of gentlemen not interested in the gas or electric lighting companies to consider the matter.

Aberdeen.—The Town Council, by virtue of its provisional order, is now busily engaged in carrying out its provisions. The total cost, exclusive of land, but including buildings, was estimated by the engineer to be £21,400; but the actual cost, now that the tenders have been received, has been found to work out very considerably less than this figure. There is good hope that the work will be completed by the end of the year. It is proposed to charge 7d. per Board of Trade unit for current.

Ipswich.—At a meeting of the Town Council last week, Mr. Pratt said the sub-committee on electric lighting had had a meeting, and that Mr. Catchpole and he were deputed to look for a site for the depôt, and he asked Mr Goddard, as chairman of the Waterworks Committee if they might visit the waterworks, for if room could be found there it would be a saving to the ratepayers of some £2,000. Mr Goddard said there could be no objection to the sub committee going to the waterworks.

Glasgow Telephones.—The report by Councillor Starke on the municipalisation of telephones in Glasgow has been discussed at a meeting of the Finance Committee of Glasgow Town Council. It was decided to recommend the Town Council to adopt the proposal contained in the report, and apply to the Postmaster General for a licence to lay down a telephone system throughout the city. In the report the necessary capital is estimated at £50,000, and with 4,000 subscribers the rent per annum for each instrument is put down at £4.

Electric and Automatic Engineering Company, Limited.—This Company has been registered by A. Aylard, Portsea Villa, Manor Park, Essex, with a capital of £10,000 in £1 shares. Object: to acquire, develop, and turn to account certain patents connected with automatic boxes worked by electrical, mechanical, or other power. The first directors—to be not less than three nor more than seven—are to be elected by the signatories to the memorandum of association. Qualification, £100; remuneration, £75 per annum; chairman, £25 extra.

Reading Tramways.—The tramways in Reading are the property of the Imperial Tramways Company, which has tramways in Bristol, Dublin, and other places. The company has just obtained electrical powers for working tramways, and it is suggested that if the Caversham to Whitley line could be arranged electric power would no doubt have to be applied to work it. The question of a new depôt has engaged the attention of the directors, and a new and more advantageous site has been selected near the Barracks terminus, Grovelands road East.

Lighting at Sevenoaks.—At a meeting last week of the Local Board, the Lighting Committee reported that they had before them the letter from Mr W. Hemmant, of Bulimba, Sevenoaks, proposing to form a company for the purpose of lighting Sevenoaks by electricity, and enquiring whether the Board would support an application for a provisional order; and the committee recommended that subject to the provisional order, as suggested in Mr Hemmant's letter, being satisfactory in detail, the Board do not oppose the proposal, but give the proposed company the usual permission in such cases.

Agency for Scotland.—Mr. W. C. Martin has ceased his connection with Messrs. Paterson and Cooper as agent for Scotland. They have appointed Mr. E. George Tidd to take his place. Mr. Tidd has for many years been connected with the firm and has personally superintended many of the most important electric light installations carried out by them in England. Mr Tidd has a thoroughly practical knowledge of electrical engineering, and is well known to electrical engineers in London. He is an associate member of the Institution of Civil Engineers and an associate of the Institution of Electrical Engineers.

Worcester.—A meeting of the Worcester Watch Committee was held last week, Alderman Hill presiding. Mr. Purches, city surveyor, reported strongly in favour of the generating station for electric lighting being at Powick Mills, on the River Teme, and pointing out that the extra power not required for lighting could be used for pumping at the waterworks, and for treating sewage at the contemplated sewage works. Mr. Preece confirmed Mr. Purches's conclusions. On the recommendation of the sub committee, the tender of Mr. T. Rowbotham, of Coventry road, Birmingham, for the erection of the generating station at Powick for £14,797 was accepted.

Madras Tramways.—The *Bombay Gazette* is informed by the secretary of the Madras Tramway Company that it is not true, as stated in one of the Madras papers, that the concession has been voided and that the deposit of 10,000 rupees paid into the municipal treasury has been forfeited. Nothing of the kind has happened. The final orders of the Local Government have not yet been issued. A special meeting of the Municipal Commissioners will be held to ask the Government to reconsider the question of the extension of the period for beginning the work. A public meeting will also be held to express the opinion of the Madras citizens, who feel very strongly on the subject.

Lighting at Weybridge.—At a meeting of the Chertsey Local Board, Mr. Yool moved that a communication be addressed to the Weybridge Electric Light Supply Company, drawing their attention to the section of the order which limited the time for removing the electric line placed above ground, and stating that the Authority did not consent to any line remaining above ground in contravention of the order. It was very important that they should proceed with the matter, because the contract with the lighting inspectors had only 14 months to run, and if the company failed to conform with the terms of the order it would be necessary for the parish to make some other arrangement with regard to lighting. Of course some time would be required to do that, and they did not want the village to be in darkness. The resolution was adopted.

Electric Traction in Liverpool.—At the half-yearly meeting of the Liverpool United Tramways and Omnibus Company, held at the offices, Pudsey street, Liverpool, last week, Mr. David Radcliffe, who presided, pointed out that during the 10 years of his chairmanship the shareholders had received dividends equal to 5 per cent., and in addition a very large sum had been put to reserve. The present lease with the Corporation of Liverpool had 11½ years to run, and it was intended to make another attempt to apply electric power as a means of haulage of tramway cars. They should first seek an extension of their lease as the capital outlay consequent upon new cars and equipment would be very costly, and one that could not be fixed on a lease of only 11½ years duration. Extensions were also required for residents near the city boundaries and outside, and when these were made the directors thought they could work useless and unused lines for which they had paid £54,810 rental in the past and were continuing to do so. Something should be done by the Corporation. They had carried in the half year just closed about 7,000,000 passengers, and their cars and omnibuses had travelled nearly 3,000,000 miles.

St. Pancras.—In the report of the Finance Committee of the London County Council on Tuesday, it was proposed that the Council should lend the Vestry of St. Pancras £15,400 towards the cost of its electric lighting works on condition that the sum was repaid in 42 years. A principle held dear by the Council is that no loan should be granted for a period longer than the probable duration of the works whose cost it is intended to defray, and in the light of this principle a diversity of opinion revealed itself as to the fitness of the conditions on which it was proposed that this particular loan should be granted. Several speakers thought the electric lighting works could not be expected to exist for 42 years, and more than one expressed a fear that the transaction proposed to be entered into would consequently be attended with financial risk. This prompted Mr. Westacott to the indignant enquiry whether any better security could be desired than the rates of St. Pancras. The debate was principally notable for the speech of Mr. Fletcher Moulton, Q.C., which reached a high oratorical level. Mr. Moulton held that 21 years was a

sufficiently long period of repayment for electric lighting works, though he was anxious to make an exception in the case of St. Pancras by reason of its being the pioneer parish in this important sphere of municipal enterprise. When it came to the vote, hostile amendments found but scanty support, and the recommendation of the committee was approved.

Electric Construction Company, Limited.—This Company has been registered by Linklater and Co., 2, Bond court, Walbrook, E.C. The capital is £400 000, divided into 150,000 ordinary and 50,000 preference shares of £2 each. The objects are to acquire the undertaking, business, and assets of the Electric Construction Corporation, Limited, upon such terms as the Board think fit, to undertake all or any of the liabilities of the said corporation, to carry on the business of electrical and mechanical engineers electricians, etc. The signatories with one share each are: Daniel Cooper, Bart., 6, De Vere gardens, S.W.; David Plunket, Q.C., M.P., 12, Mandeville place, W.; E. Garcke, Queen street chambers, E.C.; Henry C. Mance, K.B., C.I.E., Manora, Bedford; T. Parker, M.I.C.E., Newbridge, Wolverhampton; Philip E. Beachcroft, 112, Portsdown road, Maida Vale, W.; James W. Barclay, 5, Clarendon place, Hyde Park gardens, W. There shall not be less than three nor more than 10 directors exclusive of the managing director). The first are Sir Daniel Cooper, Bart., G.C.M.G.; Sir Henry Mance, C.I.E.; Right Hon. David Plunket, Q.C., M.P.; James W. Barclay, Philip E. Beachcroft, J. Irving Courtenay, James Pender, and Emile Garcke. Qualification: ordinary or preferred shares of £400. Remuneration: £1,500 per annum, and an additional sum equal to 10 per cent. of the net profits of any year in excess of the amount required to pay 6 per cent. on the ordinary paid up capital.

Liverpool Overhead Railway.—The report of the Directors of this Company for the half year ended the 30th ult. states that the railway was formally opened by the Marquis of Salisbury on the 4th February, and for public traffic on the 6th March. Owing to the delay in completing the electric signalling, only a 10 minutes' service could be worked until the 22nd May, since which date a five minutes' service has been established. The main structure of the line has been completed, and the electrical equipment has been working satisfactorily, the traffic being conducted with great regularity. The total number of passengers carried was 1,370,742, of which number 235,487 were first class, 956,922 second class, and 178,333 travelled with the cheap workmen's return tickets which the Company have recently issued. A contract has been entered into with Messrs. Holme and King, of Liverpool, for the extension of the railway to Crosby road, Seaforth, from which considerable additional traffic is expected. The Directors have decided to ask the shareholders for authority to issue the remaining preference capital of £45,000, but they do not anticipate that more than one-half will be required to provide funds for completion of the northern extension and for working capital. The accounts for the period during which the railway has been at work show that the gross receipts have been £12,352, and the working expenses, £6,990, leaving a balance carried to net revenue account of £5,361. After providing £1,623 for interest on mortgage debentures from March 6, and £122 for interest on calls paid in advance, etc., the balance available for dividend amounts to £3,644, out of which the directors recommend a dividend of 5 per cent. per annum upon the preference shares, which will absorb £351, leaving a balance of £3,293 to carry forward.

Hobart Electric Tramway.—A definite stage has been reached in the construction of the Hobart electric tramway system. The machinery at the generating station is now completely erected, and has been tested. There are four boilers of Marshall's multitubular 60 h.p. type, designed to give steam at a working pressure of 100lb. to the square inch. For the purpose of having a liberal tepid supply on hand, a huge water tank has been erected and connected with a Worthington steam pump, which forces the water through two of Marshall's 100 h.p. water heaters into the capacious reservoirs of the boilers. The necessary heat is supplied by the exhaust steam. There are three dynamos and engines. The latter are Willans's patent central valve high speed compound engines connected direct with Siemens H.B. 36-21 compound wound dynamos. They run at a speed of 350 revolutions per minute, giving off 500 volts and 250 amperes. The system adopted is the overhead type, and small galvanised steel wires have been used. These are stretched tight, and unsightliness from slack is avoided. But they lose power as the extremities of the circuits are approached, and to make up for this loss heavy feed wires are carried direct along each route on the poles. This makes the current of somewhere about equal strength over the whole line. The electricity passes down from the central overhead wire by a rubbing contact arrangement, which projects prominently aloft from the roof of each car. An insulated wire conveys it through a hollow standard to the terminal of the motors, fixed to the car carriage. From these wires the incandescent lamps for illuminating the cars are also fed. The cars were built for Siemens Bros. by the Lancaster Waggon Company, and will seat 48 passengers, divided equally between the lower and upper decks. Attached to each car are two of Siemens's electric motors of 15 h.p. each, so that the motive power on a car is equal to that of 30 horses. The plant will be strong enough, with the addition of another dynamo, to light the Tasmanian International Exhibition, and there is no little probability of this being carried out. The company's Act of Parliament empowers them to light the streets if required, but of course nothing is at present contemplated in this direction. The work of laying down the system has been done under the superintendence of Mr. C. A. Parker, who was assisted by Messrs. J. Wilkinson and T. Henwood. Mr. Lee L. Murray represents Messrs. Siemens Bros. in the colonies.

Lighting of Birmingham.—The question of electric lighting came up for consideration on Tuesday at a meeting of the City Council. The Mayor (Mr. Lawley Parker) moved, in accordance with the recommendation of the committee, that the notice of the Birmingham Electric Supply Company to apply for a provisional order extending their area of supply should be referred to the General Purposes Committee with power to take such action in relation thereto as they may think desirable for protecting the interests of the consumers and the Corporation. He said the committee had devoted much time to the consideration of this subject. A year ago they recommended that the matter should be delayed for 12 months, in order that further information might be obtained as to the success of the electric light from a commercial point of view, both in Birmingham and elsewhere; but they were agreed that, such information being obtained, they would then be bound to come to a conclusion one way or another, whether they should apply for a provisional order themselves, or whether they should grant on fair and proper terms power to the present or to some other company to extend electric lighting in the city. The Birmingham Electric Supply Company were seeking to obtain power to supply the electric light in Edgbaston and the jewellery district, and in due course they would have the details of the proposed order to deal with. It appeared to the committee that there were two ground which might justify the Council seeking for powers themselves. The first ground was a reasonable anticipation that the profits to be derived would be large, and the second was that it was necessary in order to safeguard the interests of the consumers and the public generally. In case the Corporation should decide on seeking a provisional order to supply the electric light in any part of the city, and especially the Edgbaston district and the jewellery quarter, they would have to acquire the present company's undertaking in order to make it succeed. They would have to acquire it by agreement, and he thought it was not unlikely that the company might require a considerable premium in anticipation of the future which they believed to be before them. Then they had to consider this aspect of the case, that while electric lighting was a success in some directions, they did not know that they had reached a point at which they could say, so far as the supply was concerned, that one or another was the right system, and that it might not be superseded by a better system in the future; and if they acquired the present plant, and laid down mains and so on for a new district, they might find there was a considerable deterioration in consequence of the discovery of some new system. This was a risk that ought to be taken into account before they came to a conclusion. Then they had to remember that electric lighting was a very technical matter, that they would be largely in the hands of engineers, and that the cost of working expenses would not be less, but probably greater, under the Corporation than they would be under a company. The General Purposes Committee, therefore, saw no encouragement to embark upon the enterprise so far as profit was concerned. Then with regard to the second point—the safeguarding of the interests of the public and the consumers—the Corporation had power to apply to the Board of Trade to revise the prices charged every seven years, and the period of appeal was now only three years distant. Besides this, there was no monopoly of supply; and the best safeguard was competition. The Corporation might at any time grant a concession to another company or undertake to supply the light themselves. Large consumers could also lay down their own installations, so that altogether ample safeguards already existed. On the whole the committee came to the conclusion that it would be better, for the present at least, that they should not become suppliers of the electric light and power themselves; and, therefore, that they should not oppose the application of the company for a further provisional order, except upon clauses; and here from past experience he believed they would not find the company unreasonable in negotiation with the Corporation. Mr. Reynolds seconded the resolution, which was carried.

Lighting of Chester.—Another report, this time by Mr. Preece, has been placed in the hands of the Watch Committee of the Chester Town Council, and was referred to last week at a meeting of this body. Alderman Gilbert, in view of the valuable information contained in the report, moved that it be printed and circulated among the members of the Council. Mr. J. J. Cunnah seconded. The Town Clerk (Mr. Saml. Smith) read the minutes of the Watch Committee meeting held on the 11th July, at which a notice was submitted to the effect that application was intended to be made on or before the 21st December next by memorial to the Board of Trade for a provisional order to be confirmed in Parliament in the ensuing session, authorising the Holloway Electricity Supply Company, London, to supply electricity for any public or private purpose within the area of the city of Chester. Letters were also read from Mr. Preece, in one of which he described Dr. Hopkinson as "the best man in Europe"; also his report on the prospects of electric lighting in the borough. After referring at some length on the advantages of the electric light and urging the Corporation to take the matter up in a bold spirit, Mr. Preece said in no case where the electric light had been adopted had the Corporation found it necessary to fall back upon the rates, and in no case had the introduction of the electric light injuriously affected the gas interest; indeed, it had generally the reverse effect. In Chester, with coal cheap and with water for condensing, there was no reason why the charge should be more than 6d. per supply unit, and as the gas was 3s. 4d. per thousand cubic feet, they would be able to compete with gas successfully as

regarded price. As to the installation station, the site by the market would be certainly central, but a high chimney placed there would be a nuisance and an eyesore and on the whole he considered it unsuitable. The wharf site was good for cheap carriage and water, but unless the buildings at the back, including the jam factory, could be obtained, the land would be of little use. That at present available would cost a large sum of money. The Hop-pole Paddock made a very suitable site as regarded size. Also it was near the canal, so that the water might be obtained for condensing and coal delivered cheaply. But owing to its proximity to their beautiful cathedral, it would, in his mind, be a pity to place the electric light station there if a more convenient site could be found elsewhere. Failing an outside site somewhere near the canal and railways, where land ought to be cheap, this site would, however, be the best. Assuming, therefore, that they decided upon the Hop-pole Paddock he should recommend them to use a low-pressure system, and if a demand arose in the suburbs and outlying districts too far to be reached by the low-pressure system, it would be easy to put up a small high-pressure alternating current plant, with sub-stations. If, however, they wanted to provide for the whole borough, and selected the wharf or obtained a site still further out of the town, then they must necessarily use a high-pressure system. As to the demand, Chester had a population of 37,000, and there were probably at the present moment about 40,000 gas burners fixed. It was fair to assume that about one-third of these lamps would be ultimately replaced by the electric light. The ultimate demand, allowing for the growth of population, would probably be about 20,000 35-watt lamps—i.e., there would be about 10,000 lamps burning at one time, for experience showed that the maximum number alight at one time never exceeded 50 per cent. of those fixed. He thought the Corporation would be justified in providing at present plant for only 5,000 35-watt lamps fixed. The estimated expenditure would be: buildings, £3,000; machinery, £6,500; battery, £1,000; mains, £4,000; contingencies and working capital, £500—total, £15,000. The ultimate expenditure for a plant to serve 20,000 lamps would be: buildings, £6,000; machinery, £20,500; batteries, £2,000; mains and distribution, £20,000; contingencies, £1,500—total, £50,000. At Chester the probable revenue and expenditure with 5,000 35-watt lamps fixed would be (assuming the charge to be 6d. per supply unit)—Expenses: working expenses and maintenance at 3.5d. per unit, £1,470; interest and sinking fund, £815—total, £2,285. Revenue: 5,000 lamps at 16s. per annum, £2,500, leaving a net profit after interest and sinking fund of £215. In conclusion, Mr. Preece remarked that an expenditure of £15,000 would be ample to commence with, but the buildings and equipment should be so designed as to be elastic and capable of extension with the growth of the business. It was moved by Mr. Deeley (the minutes continued), and seconded by Mr. Churton, that Dr. Hopkinson be appointed chief engineer, and be instructed to prepare a scheme, to advise on tenders, and to superintend the installation. An amendment was moved by Alderman Gilbert and seconded by Mr. Connah, that Mr. Gisbert Kapp be appointed engineer. The amendment was lost, and the original motion carried.

PROVISIONAL PATENTS, 1893.

JULY 17.

13858. **A galvanic element.** Albrecht Heil, 53, Chancery-lane, London. (Complete specification.)

JULY 18.

13888. **Improvements in electric current and current generator governors.** Charles Wiese, P. O. Box 1,071, Ottawa, Canada. (Complete specification.)

13889. **An electrical self-winding block.** John Shell Bolton and Thomas John Murday, 5, Elswick-place, Newcastle-on-Tyne.

13900. **Improvements in electric heating.** Richard George Bennett, 9, Kelmscott-road, Wandsworth Common, London.

13911. **An improved method of and apparatus for heating welding, or working metals electrically.** William Phillips Thompson, 6, Lord-street, Liverpool. (Charles Lewis Coffin, United States.) (Complete specification.)

JULY 19.

13976. **Improvements in dynamo brushes.** The London Electric Wire Company, Limited, and Henry Capel, Anchor Works, Playhouse-yard, Golden-lane, London.

13995. **Improvements in apparatus for the manufacture electrolytically of tubes and other articles of circular section.** Francis Edward Elmore, 28, Southampton-buildings, Chancery-lane, London.

13996. **Improvements in vehicles and electric locomotives for single-line elevated railways.** Fritz Bernhard Behr, 28, Southampton-buildings, Chancery-lane, London.

14000. **Improvements in and relating to electricity meters.** Sebastian Ziani de Ferranti, 24, Southampton-buildings, Chancery-lane, London.

14003. **Improvements in or connected with electric-circuit closing devices for series circuits.** Albert Augustus Goldston, 4, South-street, Finsbury, London.

14012. **Improvements in electric batteries.** Henry Bonner, 11, Furnival-street, Holborn, London.

JULY 20.

14030. **Improvements in apparatus for the suspension of electric light fittings.** Bertram Thomas, 1, Springbank, Langham-road, Bowdon, Cheshire.

14056. **Improvements in electrolytes for primary batteries.** William Heaton Longsdorf, 73, Cheapside, London.

14076. **Improvements in electric measuring instruments.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Arakelyan Harry Armen, United States.) (Complete specification.)

14087. **Improvements relating to incandescence lamps.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (The General Electric Company, United States.)

14089. **Improvements relating to the manufacture of Paris blue or Berlin blue and of Berlin green by electrolysis, and to apparatus chiefly designed for use in such manufacture.** Hugo Goebel, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

JULY 21.

14091. **Improvements relating to electric fuses.** Francis William Thomas Brain, 20, High Holborn, London.

14105. **Illumination in connection with electric gas lighters.** August Eckstein and Herbert John Coates, 45, Chapel-street, Salford, Manchester.

13130. **Improvements in the electrolysis of iodides, bromides, nitrates and other salts.** James Hargreaves and Thomas Bird, 191, Fleet-street, London.

14131. **Improvements in the electrolysis of chlorides, iodides, bromides, nitrates, and other salts, and in apparatus therefor.** James Hargreaves and Thomas Bird, 191, Fleet-street, London.

14155. **Improvements in and connected with break-feed appliances for electric arc lamps.** Frederick John Beaumont, 166, Fleet-street, London.

14157. **Improvements in or relating to electricity motors.** Harry William Charles Cox, 51, Cricketfield-road, Lower Clapton, London.

14158. **A new or improved electric lifeboat messenger and tender.** Alexander Browne, 9, Warwick-court, Gray's Inn, London. (John Archibald Cox and Arthur W. Read, India.)

JULY 22.

14202. **Improvements in multipolar dynamo-electric generators and motors.** Lazarus Pyke and Edward Stephen Harris, 53, Chancery-lane, London.

14210. **An improvement in tubular posts for telegraphic or other purposes.** Siemens Bros. and Co., Limited, and Carl Ernst Julius May, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

SPECIFICATIONS PUBLISHED

1883.

5978. **Carbons for electric lamps.** Swan. (Second edition.)

1891.

536. **Dynamo-electric generators.** Atkinson. (Second edition.)

1892.

12665. **Secondary batteries.** Garassino.

13207. **Incandescent electric lamps.** Stern.

13358. **Alternate current circuits.** Mordey.

13507. **Electric conduits.** Scott.

NOTES.

Aniline.—A process of manufacturing aniline by electrolysis has been devised.

Telephone Wires.—It has been decided to permit the telephone wires in Manchester to be placed underground.

New Engine.—A new petroleum engine has been brought out by Messrs. Stephenson, of Newcastle-on-Tyne.

Liverpool Electric Railway.—It is suggested that it would be advantageous for the company to introduce season tickets.

St. Pancras.—It is suggested that arc lighting should be introduced in Gray's-inn-road and in the neighbourhood of King's Cross.

Traction in Westphalia.—It is said that Messrs. Siemens and Halske are to lay down a series of electric tramways in Rhenish Westphalia.

Lemberg.—Two lines of tramway are to be constructed and electrically equipped by Messrs. Siemens and Halske, and are to be ready for an exhibition next May.

Junior Engineering Society.—The summer excursion this year to Wilts., Devon, and Cornwall, is to commence on Friday, the 11th inst. Copy of programme may be obtained of the secretary.

Remscheid.—The electric tramway started last month has become so popular that the cars and plant are unable to deal with the traffic; hence the number of cars is to be increased from 11 to 20, and additions made to the generating plant.

Perseverance.—The result of perseverance is shown by the public statement made the other evening by a well-known electrical engineer that 15 years ago he was trying to eke out a living by teaching elementary science, whereas now he is an inventor and a prosperous man.

Accumulator Plates.—In a new composition M. Worms takes 945 parts of lead, 22 of antimony, and 13 of mercury. The lead is first melted, then the antimony is added, and finally the mercury is poured in only at the moment of running the composition in the mould.

Siam.—To keep up with one of the leading questions of the moment, a news agency telegraphed from Washington on Wednesday that an electric tramway, three miles long, has been put in operation at Bangkok by American capitalists. We believe the tramway was started some months ago.

The Institution.—Among the papers to be read during the next session will be one on "The Electrical Transmission and Distribution of Power at Niagara Falls," by Prof. George Forbes, F.R.S., member. A paper upon "The Electric Lighting of the City of London" has also been promised by Sir David Salomons, Bart., vice-president.

Owen's College, Manchester.—We are informed that the prize for the best essay on the technical applications of electricity has been awarded to Mr. J. R. Ashworth. This prize, of the value of £10, was given in the present year by Dr. Edward Hopkinson, the subject of the essay being "The Testing of the Efficiency of Dynamos and Motors."

Railway Station Lighting.—The Northern Railway Company of France—in accordance with its practice as already carried out on many of the stations along its lines—intends shortly to arrange for the electric lighting of the station at Montreuil-sur-Mer by means of accumulators, the necessary power being supplied by an engine used at the present time for pumping water.

Lighting of Balloons.—The "Phœnix," a German balloon, with which scientific investigations are being conducted at night, is lighted by four incandescent lamps, energised from a small battery arranged on the car. A captive "aerial castle," proposed to be used at the projected exhibition in Antwerp next year, is to be illuminated at night by many thousands of electric lights.

Traction in Leeds.—The majority of the Corporation, as the mayor recently mentioned, is in favour of electric traction, and probably, when the town acquires the tramways, electric traction on one system or another will be adopted. In this connection it may be well to record the fact that arbitration proceedings in the direction of purchasing the lines have taken place, and the decision of Sir Douglas Galton on the matter is expected in a month.

Chicago Electrical Congress.—The Royal Commission for the Chicago Exhibition has appointed Major-General C. E. Webber as one of the delegates to the electrical congress to be held at the exhibition. We understand that General Webber's name has been forwarded to the Secretary of State for Foreign Affairs for transmission to Chicago through the American Ambassador, and that Sir Henry Woods, secretary to the Royal Commission, who is now at Chicago, has been informed of the appointment.

Lighting in Manchester.—The generating station of the Corporation is now being set to work. It is situated in Dickinson-street, and on Monday the Free Trade Hall was lighted for the first time. On Tuesday arrangements were completed for the turning on of the light at the Bank of England, and other buildings within the area of supply will be connected to the mains as expeditiously as possible. It is expected that so far as the orders already received are concerned, the work will be completed by the end of this month.

South London Railway.—It is noteworthy that the percentage of working expenses to gross receipts is gradually diminishing. The first half-year the line was worked the expenses were 79 per cent. of the receipts, the second half-year 76 per cent, the third half-year 70 per cent., the fourth 67·0 per cent., and the fifth and last 64·6 per cent. These figures included the lifts, and if these were deducted the expenses would only be about 56½ per cent., which is very nearly the same as on ordinary railways.

Koenigsberg.—Those interested in central-station work will find a full illustrated description of the municipal lighting of Koenigsberg, Prussia, by F. Uppenborn, in the *Electrotechnische Zeitschrift* for July 21. The installation was carried out by Naglo Bros., of Berlin. Vertical engines driving the dynamos direct are used. Diagrams of connections are given. Not the least interesting parts of this installation are the switchboard, worked by handle and gear, and the ventilation of the junction-boxes in the streets by air-shafts.

Traction in Vienna.—A commission of the Municipal Council has, in consequence of the proposals of the Vienna Tramway Company for improving the facilities for transit, been considering the subject. The commission regard the introduction of electricity as the motive power on tramways as a suitable method for removing the many difficulties encountered in the working of the lines, for facilitating the continuation of separate lines through the inner town, and for increasing the speed and carrying capacity of the tramways. A change in this direction was, however, not to be entirely carried out as proposed by the tramway company, but the system must be extended in all parts of the city

where there was plenty of traffic. The recommendations of the commission have been adopted by the Municipal Council.

City and Guilds of London Institute.—The council, on the 31st ult., awarded the diploma of associate of the City and Guilds Institute to the following third-year students of the Institution: Civil and mechanical engineering—K. W. Digby, G. A. Fry, G. H. Heelas, R. F. Krall, H. F. Robinson, A. E. H. Sonneborn, C. V. Drysdale, T. L. D. Hadwen, E. L. Joselin, H. C. Leake, R. D. T. Roe, and W. T. W. Sussman. Physics and electrical engineering—G. H. Ballie, W. A. Brodie, W. Casson, J. R. Dick, A. H. Finlay, E. E. Gunter, W. E. Miller, J. Barnard, R. B. Burrowes, W. R. Cooper, W. H. Everett, E. G. Fleming, T. Hemmant, N. Ward, and C. H. C. Woodhouse. Applied chemistry—O. F. Russell.

Accumulator Cars in Milan.—As mentioned in our last issue, the starting of the storage battery cars in Milan took place on the 20th ult. in the presence of members of the local authorities and others. The cars, which have been made by the Oerlikon Engineering Works, are of the same type as those shown by the latter at the Frankfort Electrical Exhibition. Each car accommodates 34 passengers, 18 being seated, and the remainder being carried on the two platforms. The battery is composed of 64 cells arranged under the seats, and has a capacity of 200 ampere-hours. The motors are of 10 h.p., and the maximum speed obtainable is said to be 20 miles an hour, but a rate of only 11 miles is permitted. The journey from Milan to Monza is accomplished ordinarily in 55 minutes, but with the electric cars it is done in 35 minutes.

Electricity a Disinfectant.—The "medical electrician" claims that the germ of life is electricity! but apparently it is capable also of destroying life to an equal extent. This is a contradiction in terms and probably also in facts; but let that pass. Mr. Albert E. Woolf has devised a method of disinfecting sewage by the electrolysis of sea water. At Brewsters, a small town situated about 20 miles from New York, it was found that sewage was percolating through a marsh into one of the streams from which New York derives its water supply; and to remedy this, a steam plant of 15 h.p. has been put down for the purification of the Brewsters sewage. The dynamo furnishes 700 amperes at a pressure of 5 volts, a current amply large enough to electrolyse and thoroughly disinfect the liquid sewage from which danger arose.

An Early Electric Railroader.—The United States patent office electrical department must have a pretty lively time of it what with glow lamp and trolley wire claims to priority of invention. The latter subject has an especial interest just now from the enormous developments which promise to take place during the next few years; and no surprise would be felt at efforts being made by all the traction interests to obtain the earliest patents on fundamental points. Mr. T. C. Martin, the well known joint editor of our New York namesake, has however unearthed a certain Dr. Cotton, who was born as long ago as 1814, and in 1847 constructed an electric locomotive which ran upon insulated rails, one being used for the lead and the other for the return. Dr. Cotton is still alive and vigorous, maintaining a prosperous dental business in New York City.

The Three-Phase Systems.—An installation of electrical transmission of power on the three-phase system has recently been set in operation at Wangen in Wurtemburg. There are two power stations about one mile apart. The chief depôt contains a dynamo of 200 h.p. running at 265 revolutions, and driven indirectly by a Girard turbine. After passing through the measuring instruments, the current is transformed up to 5,200 volts. At the second generating station the power is obtained from the reserve of a timber yard, and this is used to operate a 100-h.p. dynamo. The current from this is also transformed up to 5,200 volts, and both machines supply into one set of mains, which are carried overhead a distance of 5½ miles to Wangen. Here the current is led to three transformer stations, where it is converted down to 110 volts. At this pressure the current is used for street lighting, and for operating motors in various establishments.

Schuckert's Electrical Plant.—Messrs. Schuckert and Co., of Nuremberg, have issued a pamphlet giving a short account of the development of their works, which were first established in 1873. It is published in connection with the company's exhibits at the Chicago Exhibition, and a copy of it has reached us from Mr. C. A. Muller, of Bradford, who is the general agent in this country. The pamphlet, which traces a history of the progress of the firm, contains some excellent views of the works and shops, and illustrations and descriptions of the company's dynamos, arc lamps, measuring instruments, searchlights, etc. A description, with plans and sections, is given of the Hanover central station, which was carried out by the firm. The extent of the works is shown by the fact that 1,500 persons are employed, and the annual output amounts to more than 1,000 dynamos and 6,000 arc lamps, apart from other apparatus.

Electric Elevators.—Some efforts—though not very extensive as yet—have been made by the Otis Elevator Company of London to develop the employment of electricity for operating the elevators that become an essential part of the large buildings now so common in our large cities; but there is, one would think, ample scope for a rapid increase in these appliances, seeing that a supply of current may be obtained so easily in the centres of population. A diagram, accompanied by figures as to cost of operation, etc., is given by the *Canadian Engineer* in a recent issue, showing the current required by an electric elevator in a Toronto building, where the cage takes 16 seconds to ascend. To do this the motor requires 70 amperes at a pressure of 230 volts; and current being charged by meter at the rate of four cents—or, say, 2d. per horse-power—the cost per round trip is not more than one fifth of a cent—or, say, one-tenth of a penny.

Technical Training.—Under the head of "The Student Course at Lynn," Mr. John E. Pitman has given in the "Year-book of the Society of Engineers," Minnesota University, details of how to apply for admission as a student at the expert department of the General Electric Company of America. Over 700 applications, it appears, are now on file (which beats Prof. Kennedy's 380); an average of four a day come in, and 85 per cent. are college graduates. The course may include six weeks in the shop plant, 11 weeks in the arc department, and 10 in the continuous incandescent; nine weeks with motors and generators, 11 weeks with the alternating system; three weeks in motor testing, and two in the blacksmith's shop. In addition, experimental work is done, such as testing special machines. In return, students are paid for the first three months 2½d. an hour, then 3½d., and 5d., and for the last three months 6d. an hour. If they stop after the year, 7½d. an hour is paid. The working day is nominally of 10 hours.

Fatal Accident in Rome.—An accident, resulting in the death of two trimmers, occurred last week in Rome. An arc lamp in the Piazza of the Quirinal became extinguished, and one of the men, placing a ladder against the

standard, mounted and neglected to switch off the current before taking hold of the carbons. The result was that he was instantly killed, and his companion not knowing that the current had not been turned off, endeavoured to rectify matters and met with the same fate. Questioned on the subject by a correspondent, Prof. Mengarini, a well known Italian electrical engineer, said that the pressure of the current which killed each of the two men, and which only left a very slight burn on the fingers, was of 2,000 volts, and that it was an alternating current of 5,000 alternations per minute. He had seen the bodies 10 minutes after death, perhaps even less, and the expression on the face of each was perfectly calm. It was his opinion that there was no necessity to keep the current on for so long a time at executions in America.

A New Lamp Filament.—We have been favoured with specimens of a new compound material for incandescent lamp filaments. It has been produced by Mr. A. Shippey after four years' experiments. The material can be pressed into sheets and cut into different shapes according to actual requirements, or it can be drawn into very fine wire. The material is termed "Fiberite." We are informed that when carbonised by a new process devised by Mr. Shippey, the filaments are rendered very strong, and capable of standing from 150 to 200 volts in case of need. Messrs. Shippey state that the new lamps are made both in vacuous and non-vacuous types, the bulbs in the latter case being filled under pressure with a highly-attenuated vapour, and as the bulbs can be filled in batches of 500 to 1,000 at a time, great economy is said to be obtained by this new process of manufacture. It is claimed that good lamps can be produced on this method, and be sold to large consumers at from 8d. to 8½d. per lamp, and that the annual cost to consumers will amount to 1s. per lamp.

The Chicago Electrical Section.—In a letter to the *Times* of Wednesday, Mr. Conrad W. Cooke, who had agreed with one of the Royal Commissioners to proceed to Chicago to act as judge in the electricity section, complains of several postponements of the work of the judges, and through which he had been obliged to send in his resignation. Apart from personal matters, he states that the conditions imposed upon the judges are impossible to fulfil. Continuing, he says:—"According to the instructions, each judge is required to examine every individual object exhibited by every exhibitor in his section, and to make a report in writing, over his signature, thereon, stating his reasons for giving or withholding an award to that particular object; and, moreover, he has, in addition, to prepare an abstract report upon each object he examines, and such abstracts are to be inscribed in the diploma to be presented to the exhibitor, while the full reports are to be published afterwards and will form part of the literature of the exhibition. The fulfilment of such a condition would involve many months of the closest possible work."

Increasing Tractive Power.—The tendency of electric street tramway practice in the United States—says Mr. W. E. Harrington, in the *Electrical World*, is towards the use of a single motor, operating as a rule on one axle; but owing to steep grades and large loads, necessitating heavy currents, it is found that there is often a difficulty in preventing slip, if not even occasional overloads of the motors. Accordingly, the above-named gentleman suggests the use of two magnetic pulleys—one on each axle—connected by means of a flexible iron band. The magnetising coils of these pulleys are switched in and out in series with the motor, so that the adherence varies directly with the current; both axles are thus driven by the motor, and therefore it is claimed that the tractive power is very materially increased at slight expenditure of electric energy. The appliance is ingenious enough, but one would doubt whether the gain more than counterbalanced actual loss of current, with the greater complication, as compared, say, with the use of differential gear thrown in and out by means of a magnetic clutch.

Lighting by Reflected Light.—The Société Alsasienne of Belfort uses to a considerable extent the method of reflecting the light of the arc lamp from the ceiling. The positive carbon is placed below so that the hollow crater throws its rays upwards to a reflecting screen. For rooms 11ft. in height the company recommend 10-ampere lamps, and for rooms of 15ft. a 15-ampere lamp. The price of a complete installation is estimated on the average as £16 per lamp of 10 amperes, and £20 per lamp of 15 amperes; and the motive power 0·8 h.p., and 1·2 h.p. respectively per lamp. The working expenses are given at £4. 16s. and £6. 8s. for these two kinds of lamps per year of 700 hours. This method loses part of the light, but where the walls and ceilings are whitewashed, it has the advantage of giving absolutely no shadows and of furnishing a light more nearly that of daylight than any other artificial light. In spinning and weaving mills it is found to take 25 per cent more power than with incandescent lamps, but the superior advantages more than compensate for the loss. It is also recommended for school lighting as being less injurious to the eyes of children than other lights.

Central Stations in France.—We have no great reason to feel proud of the "rapidity" shown by this country in developing the supply of electric energy for lighting purposes, although the past two or three years show an improvement in this respect. Statistics of what has been so far accomplished by our neighbours across the Channel, as published in *L'Industrie Electrique*—give a total of 255 central stations for the distribution of electricity, so far as can be ascertained up to the beginning of last month. Of these, 209 employ plant and apparatus for the generation and supply of continuous currents, 39 are designed on the alternating-current system, whilst seven possess appliances suited to both methods. Besides the grand total of stations already at work, there are 68 now being constructed, or very shortly to be undertaken. Nineteen have been put into operation since the beginning of the year, being a proportional increase of 7½ per cent. The total power available in these 255 stations, which, by the way, do not include the Parisian "sectors," is approximately 30,800 h.p. The price of current when taken under contract is about £1 for each 8-c.p. lamp per annum, the light being available from sunset to sunrise; but a rate of 35f. to 38f. (say, 28s. to 30s.) is by no means uncommon. When supplied by meter, the lowest rate is 30c. (say, 3d.) per unit, the average price being 90c., or 9d. Consumers prefer, however, to an increasing degree to take their current by meter rather than under contract.

Fowler-Waring Cables.—A copy of the new issue of the catalogue of the Fowler-Waring Cables Company, Limited, of 32, Victoria-street, S.W., has been forwarded to us. The types of cables made by the company are well known, and they are used by, among others in this country, the London Electric Supply Corporation and the City and South London Railway. Of the new features in the present edition may be mentioned the many illustrations of different kinds of junction-boxes and fittings for lead-covered cables, and which have been extensively adopted. It is usual to make the boxes of cast-iron, but gunmetal is used for exceptional positions. Some of the boxes have the connection to the cable made through a watertight screwed gland, whilst others are fitted with a brass tube

which is plumbed to the cable by a wipe joint. The company, however, recommend a connection where a tinned solder pocket surrounds the cable, and which when filled unites the metals and is absolutely watertight. The introduction of the junction boxes has in a large measure been the means of overcoming the difficulty first experienced in the jointing of the mains and in distribution from them. The company have brought out a system of concentric conductors and fittings, which are fully described and illustrated in the catalogue, and which has been largely adopted in this country and abroad. Telephone cables of both the solid and dry core type are described at length, together with illustrations. The catalogue is well got up and should be in the hands of all electrical engineers.

Water Power for Central Stations.—One can hardly take up a single number of any continental electrical trade journal without finding details here and there, paragraph after paragraph, and article upon article, respecting the use of water power for the economical generation of electricity—whether to light up houses and streets, or operate an electric tramway, and other such purposes where the electric motor is required. The number and importance of these natural power resources are so great that an English central-station engineer almost feels his mouth watering when he vainly sighs for such ready means of obtaining a cheap supply of power to drive his generators. Take, for instance, the details given in another note with respect to the total number of central stations now actually at work in France: of the 255 there mentioned, no less than 155, or, say, three-fifths, are operated either wholly or partially by means of hydraulic power; and this fact leads to the very curious result that very often it is the small towns—and even villages—which are able in this way to avail themselves of both public and private electric lighting long before some of the most important cities and large towns advance to a similar position. Probably very few of our readers have ever heard of Saint Didier-la-Seauve. This is an unimportant place of only 5,000 inhabitants, yet it has a water-power plant, driven by a 19ft. 6in. fall in the river, giving about 40 h.p. From this station current is supplied for lighting at 7½d. per unit, or by contract, according to the purposes for which the the building is designed—cafés and restaurants, about 30s.; shops, 25s.; apartments, 20s.; offices, 17s., per annum for each 8-c.p. lamp. Lamp renewals are undertaken at a fixed rate, slightly under 2s. per lamp per annum. Motive power is supplied at from £4 to 36s. per horse-power per month, according as the power of the motor is less or more than 5 h.p.

Accumulator Cars in Paris.—It looks as if Paris would demonstrate the practicability of running accumulator cars on a practical scale before London after all. The St. Denis lines of two routes, each six miles long, are both worked on this system, and another line of three miles is to be added. M. Max de Nansouty, in *Le Génie Civil*, gives (Vol. XXII., p. 197) details and illustrations of the cars used. Each car seats 50 passengers, and travels at 7½ miles an hour, with an increase to 10 miles per hour outside the fortifications, with a minimum speed of 3¾ miles per hour on the steepest gradient of 4 in 100. The weight of accumulators is 2·6 tons. The car bodies rest on two truck frames each with one axle and a separate motor which is geared to the axle by two sets of geared wheels, the angular velocity of motor and axle being as 12 to 1. The motors are of the Manchester two-pole type excited in series, and each capable of developing 10 kilowatts at 200 volts for 1,350 revolutions. The efficiency between motor terminals and axle is given as 73 per cent. Laurent-Cely cells are employed in a battery of 108 11-plate cells, which are charged by Desrozier dynamos. The batteries have an efficiency of 70 per cent. They give a maximum of 70 amperes or 1·8 ampere per lb. of active material at an E.M.F. of over 200 volts. The average discharge current is 35 amperes. Each set of cells will take a car 40 miles on grooved rails or 75 miles on vignole rails—a fact that speaks loudly for the latter. The battery is divided into four groups enabling either 50 or 200 volts to be used to obtain varying speeds. The motors are usually connected in series, but may be connected in parallel for greater speed or power. Backward or forward running is obtained by reversing the current in the fields, and either motor can be cut out in event of accident. The weight of a loaded car is 13½ tons of which 2·6 is for cells and 3·5 tons is for passengers. The cars make eight or nine double journeys per day, corresponding to a distance of 92 or 104 miles, as against 62½ for the horse cars.

Simultaneous Contrast Colour.—A paper is given by Mr. Alfred M. Mayer (*American Journal of Science*, July) on the phenomena of contrast colour, and on a photometer for measuring the intensities of lights of different colours. A ring is formed of white cardboard by cutting an opening from a disc. Another ring is made with narrow radial arms to support a larger disc of white linen tracing-paper. The disc is stretched and screwed between the rings, and the whole mounted on a stand. The screen so formed is placed in front of a petroleum lamp, and the daylight is excluded from the side thus illuminated. The other side is illuminated by the light of the sky from a distant window. The cardboard ring is thus illuminated on one side by the lamp and on the other by the daylight. The translucent paper transmits the lamplight to the side facing the window, while it transmits daylight to the side facing the lamp. On the side of the screen facing the window the cardboard ring appears cyan-blue, while on the side facing the lamp the ring appears orange. The intensity of the colours will excite astonishment even in the minds of experimenters in colour contrasts. The colours are complementary. The author made some experiments on simultaneous contrast colours produced by the electric flash. In the case of the discharge of a large induction coil, the author had shown (*American Journal of Science*, December, 1874) that when the striking distance between brass ball electrodes is only one millimetre, with a Leyden jar of 242 square centimetres of surface in the circuit the discharge lasts $\frac{1}{24}$th of a second, and is formed of over 120 separate sparks, but as the striking distance is increased the discharge is formed of fewer and fewer components, till at one or two centimetres the discharge is a single flash. In the experiment the striking distance was 8cm., and a single flash was given whose duration may be safely taken as less than one-millionth of a second. In a dark room the flash gave vivid contrast colours, the grey ring appearing bright pink on an emerald green ground and of bright yellow on an ultramarine ground. The author investigates the period of time necessary to distinguish the colours and form a judgment on them. It is less than $\frac{1}{7}$th second. These contrast colours are used by the author in a photometer disc to compare lights of differing colour. Two circular discs have eight sectors cut out, and between these was placed a circle of white translucent tracing-paper. A black disc covered up most of the central part, leaving alternate squares of cardboard and translucent paper round the rim. Experiments were made to test this apparatus as a photometer. The disc was rotated opposite mirrors inclined at 150deg. One side illuminated by daylight appeared white tinted yellow, and the other side facing the lamp appeared white tinted blue. To bring these to the same hue, a compound disc was

placed on the daylight side formed by three split discs of red lead, chrome yellow, and white cardboard. On the lamp side a disc of three split discs of ultramarine, emerald green, and white. On rotation, these combinations gave orange-yellow and bluish-green respectively, and the contrast effect of these brought the light in the translucent part to the same hue on both sides. The apparatus is used as photometer with very good effect.

Electric Eels at the Zoo.—A series of experiments has been conducted at the Zoological Gardens by the naturalist contributor to the *Spectator* on a couple of electric eels, with remarkable results. "The largest of the pair, about 4½ft. in length, thick and deep, and probably weighing from 16lb. to 18lb., was moving sluggishly on the bottom of the tank, and was slowly raised to the surface by a landing-net.. When grasped in the middle of the back there was just time to realise that it had none of the 'lubricity' of the common eel, when the first shock passed up the arm with a 'ticker' identical with that which a zigzag flash of lightning leaves upon the eye, and, as it seemed, with equal speed. A second and third felt like a blow on the 'funny bone' and the hand and arm were involuntarily thrown back with a jerk which flung the water backwards on the pavement and over the keeper who was kindly assisting in the enterprise. This slight mishap recalled a far less agreeable result of a shock inflicted on a previous enquirer, whose recoiling hand had struck the assistant a severe blow in the face. Unwilling to be baffled by a fish less in size than the salmon which form the common stock of a fishmonger's window, the writer once more endeavoured to hold the eel at any cost of personal suffering. But the electric powers were too subtle and pervading to be denied. The first muscular quiver of the fish was resisted, but at the second, the sense of vibration set up became intolerable, and the enforced release was as rapid and uncontrollable as the first. The smaller eel was neither so vigorous nor so resentful as its fellow. But a third shock was equally intolerable with that given by the larger fish. The electrical power seems to increase rapidly in the heavier eels. One of 5ft. in length, which appeared to be nearly dead when it arrived at the gardens, and was therefore handled without ceremony, inflicted a shock which, as the keeper stated, 'nearly sent him on his back.' This power of projecting its electric discharge, either through the water or by means of any conductor, to the object which it desires to paralyse, may well be observed at the Zoo. It is when in pursuit of the small fish which form its food that the 'range' of the eel's battery is best seen. On the last occasion on which the writer was present at the eels' feeding hour, eight or ten lively gudgeon were taken from a pail and placed in the eels' tank. The small fish at once dived to the bottom, as is their habit, and sought refuge at the corners, or at the angle made by the meeting of the base and sides of the stone cistern. Everyone of the fish was killed by electric shock before being eaten, but in the case of those in the corners it was impossible for the fish to bring the electric organ, which lies on each side of the lower part of the tail, into direct contact. The eel, therefore, swam past them like a torpedo boat which intends to discharge its broadside torpedoes, and as the battery came opposite the fish gave a slight quiver, which instantaneously produced a violent shock in the gudgeon, and turned it belly upwards. One fish which was shocked and left for dead while the eel went in pursuit of more, recovered after a few minutes, and was subsequently pursued, received a direct shock from the eel's side and was killed. The inference suggested by the writer's own experience of the violence of the shocks inflicted, though with different degrees of intensity, is that the eel controls the power of the electrical discharge at will, and that the gudgeons received enough, and no more, than was sufficient to paralyse them, and make them easy victims for the slow-moving eel."

New Method of Heating. M. Jules Neber, writing in the New York *Electrical Engineer*, July 12, with reference to the new method of electric heating by plunging a metal electrode into an electrolyte, says he has experimented on the same subject in the Westinghouse laboratories, and his experiments lead to a somewhat different explanation of the heating effect. It has been said that the resistance of the coating of hydrogen generated round the iron is sufficient to produce the heating. But in one of his experiments he sent 300 amperes at 125 volts without obtaining any considerable heating of the iron—the total energy being consumed by electrolysis of the water and heating of the electrolyte. But this was when the iron cathode was immersed before the current switch was closed, so that the hydrogen coating was present but effected no heating. By closing the switch *before* immersing the iron the whole experiment is changed. The moment the iron touches the water the amount of hydrogen generated separates the liquid from the metal, and an arc is drawn. The effect is more brilliant if an insulated wire is used so that an arc is produced at one place only, and wholly under the surface. The apparatus used was a glass jar 8in. high and 5in. diameter, filled with water containing 25 per cent of sulphuric acid. The positive pole consisted of a ⅛in. sheet lead cylinder, the edges standing apart about 2in. to allow the inside of the cell to be seen. The iron cathode consisted of a ⅜in. round iron bar, connected to the dynamo cable and fastened to a wooden stick. Several tests were made. With 20 amperes at 150 volts, a weight of 15 grammes of wrought iron was brought to melting heat in 15 seconds, the iron actually dropping down to the bottom of the jar (which was protected by a disc of lead). In 15 seconds 15 grammes of iron were raised 2,000deg. C., and 1,500 grammes of water 3deg. C. The heat employed in the melting of the iron is 2,000 (deg.) × 15 (grammes) × 0·1,138 ÷ 15 (seconds) = 250 gramme-calories corresponding to 1,048 watts; in the water 3 × 1,500 × 1 ÷ 15 = 300 gramme-calories, or 1,257 watts, and the power consumed in electrolysis equals 20 amperes × 1·5 volts (counter E.M.F.), or 30 watts, making a total of 2,335 watts accounted for out of 20 × 150 = 3,000 watts. There is still 665 watts equal to 159 gramme-calories to dispose of for radiation and conduction, which is about equal to 29 per cent. of the heat utilised in iron and water heating. The efficiency is thus approximately (for the calculations cannot be considered exact) 35 per cent., as 1,048 of the 3,000 watts are utilised in heating the iron. Other metals, as copper and lead, are melted quicker or slower, according to their conductivity for heat. Carbon is heated in a very short time, but the melting off of amorphous carbon, as reported by the Belgian experimenters, could not be obtained, and the authenticity of this phenomenon is doubted. It is to be noticed that using a low E.M.F. as 100 volts the heating is scarcely perceptible, though the current is about the same, probably because the arc is not long enough; 125 volts seems the critical voltage. By changing the poles oxygen is obtained in the iron cathode, which causes explosions in combining with the hydrogen chemically developed by the contact of the iron with sulphuric acid. The practical advantages of the process, says the author, is undoubtedly in the total absence of oxidation of the heated metal, and this feature might probably lead to an extensive use of the process. For the experimenter the phenomenon of wrought iron melted like wax in a glass jar filled with water is one of the most striking imaginable.

THE PREVENTION AND CONTROL OF SPARKING.*

BY W. B. SAYERS.

In the course of the discussion upon my paper dealing with the control of sparking in short air space dynamos, Mr. A. P. Trotter and several other gentlemen suggested that I should give some definite information about the relative cost and efficiency of a machine on my principle, compared with an ordinary smooth-core machine. In complying with these requests it seemed to me that I could not do better than compare a machine of my design with the Edison-Hopkinson machine, which was described in the celebrated paper on "Dynamo-Electric Machinery," by Drs. J. and E. Hopkinson, read before the Royal Society in 1886.

The particulars of the Edison-Hopkinson machine given herein are partly taken from Dr. S. P. Thompson's "Dynamo-Electric Machinery," and partly from specimens of the machine, several of which I have had experience of from time to time. There is no sparking whatever at the brushes of this machine when working at full load, and I believe the limit of output is fixed by the heating and by the mechanical strength of the armature. I have, therefore, in my design kept the total magnetic flux through the armature, and also the magnetic density, the same as in the Edison-Hopkinson machine.

The total flux through armature core when the machine is running without load is about 10,530,000 C.G.S. units.

The E.M.F. is generated by 20 coils in series, which cut the field of force four times per revolution. We have, therefore, if we take the speed at 750 revolutions per minute,

$$E = \frac{10{,}530{,}000 \times (4 \times 20) \times 750}{60 \times 10^8} = 105 \text{ volts.}$$

FIG. 1.

In my design I make the number of coils on the armature 38, and the E.M.F. is generated by 19 coils in series and two "commutator coils," or "reverser bars," as I prefer to call them in a machine of this size, because they only pass once from end to end of the armature, without going round the ends. The two reverser bars add an E.M.F. equal to one main armature coil, because, although the E.M.F. induced in one of them is only half that induced in an armature turn, they carry the whole current, and thus add their half-turn E.M.F. to both halves of armature. Thus we have

$$E = \frac{10{,}530{,}000 \times \{4 \times (19 + 0{\cdot}5 \times 2)\} \times 750}{60 \times 10^8} = 105 \text{ volts.}$$

The diameter of the new armature over all is $11\frac{1}{4}$in.; at the bottom of the tunnels, $9\frac{1}{4}$in.; and of the hole through the centre, 3in. The length of the core is 20in. The area of the iron in the core of the armature is thus, allowing 5 per cent. for paper,

$$20 \times (9{\cdot}25 - 3) \times 6{\cdot}45 \times \frac{95}{100} = 768 \text{ square centimetres.}\dagger$$

The induction density in the armature core will be

$$\frac{10{,}530{,}000}{768} = 13{,}700.$$

* From the *Journal* of the Institution of Electrical Engineers.

† The area of iron of core of armature of E H machine is given in Dr. Thompson's book as 810 square centimetres, but apparently this has been reduced, as the cores of two armatures which I have had the opportunity of measuring have only had a section of about 770 square centimetres of iron, excluding the three discs of ¼in. thickness which are in the Edison-Hopkinson armatures.

The air space I make 0·25 centimetre, or about 0·1in. The tunnels are shown full size in Fig. 1; they are 0·125in. below the surface, 0·875in. deep, and 0·437in. wide. The crown of the tunnel is slotted through to lessen the self-induction of the conductors.

The main winding would be of rectangular conductors 0·3in. × 0·25in., and the "commutator coil," or reverser bar, 0·3in. × 0·15in. These conductors and the tunnels

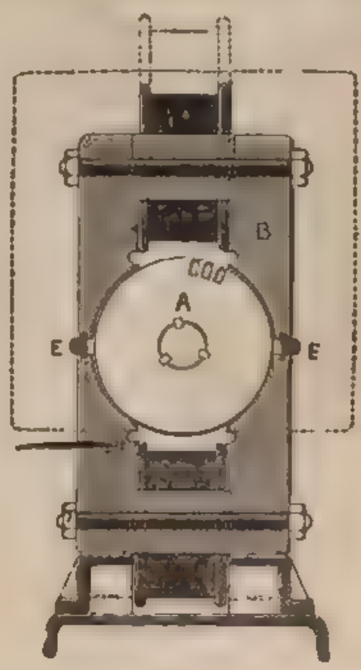

FIG. 2.

which contain them are shown in section, full size, in Fig. 1. The main conductors, C, may advantageously be made up of eight wires of rectangular section, covered together so as to form a stranded conductor. The object of the stranding is to facilitate bending. The current-density at full load of 320 amperes will be 2,150 amperes per square inch, against 2,460 in the Edison-Hopkinson machine.

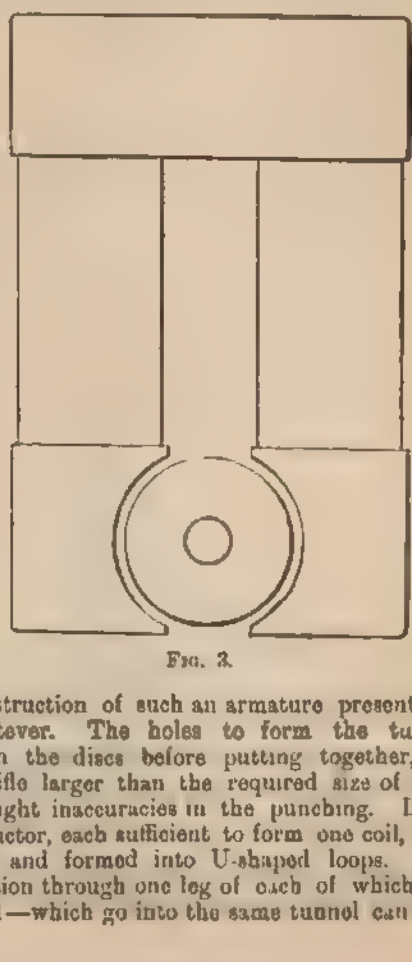

FIG. 3.

The construction of such an armature presents no difficulty whatever. The holes to form the tunnels are punched in the discs before putting together, and are made a trifle larger than the required size of tunnel to allow of slight inaccuracies in the punching. Lengths of main conductor, each sufficient to form one coil, may then be cut off and formed into U-shaped loops. The two loops—section through one leg of each of which is shown at C, Fig. 1—which go into the same tunnel can be taped

together, and the reverser bars—section of one of which is shown at D, Fig. 1—with them, and then slid in from the commutator end. When all the U-shaped loops are in position, their free ends may be bent and connected up in the same manner as that adopted in the Edison Hopkinson armatures, so as to form the main winding; but instead of soldering the ends of the coils into the commutator lugs at the time of connecting up, as is done in the Edison-Hopkinson armature, the ends of the reverser bars can be soldered to the points of connection between the coils at the same time as they are connected up. The reverser bars run back through the tunnels to the commutator. Fig. 2 represents in section at right angles to shaft the new design. Fig. 3 represents the end view of iron only of Edison Hopkinson machine, to same scale.

The dotted line in Fig. 2 indicates a single-limb magnet. A great additional saving of weight, however, is obtained by making a double magnet, as shown in full; and the value of the iron saved more than covers that of the additional wire required. The top and bottom halves of the magnets are separated by four brass distance pieces of the section shown at E. These may be, say, 3in. long, and placed one at each corner of the magnet limbs; gaps will thus be left for ventilation. Below are given the comparative electrical data, weights, and values of material in the two designs.

ELECTRICAL DATA.—*Armature.*

Total weights of parts enumerated above	39·5cwt.			18·8cwt.		

There will be a further saving of weight of material in the bed-plate on account of the lighter magnets; and if required compound-wound, the whole cost of material and labour for this will be saved, as the new design will "compound" without any series coils.

As regards the cost of workmanship, so much depends on the details of the design, and the means employed for performing the various operations, that I think it would hardly serve any useful purpose to give my estimate for these.

In addition to the saving in weight and cost of materials, I must claim for the new design great superiority from a mechanical point of view. Each disc of the armature is positively driven by the three keys upon which it is supported; the conductors are positively driven—whether or no there is any force exerted upon them; and the armature presents a smooth iron surface which is not liable to damage from careless or unskilful treatment. The space left for insulating material in Fig. 2 is ample for 100 volts, as I have proved by considerable experience: the normal insulation resistance to the iron in such an armature would be two or three megohms. If a much higher voltage were required, the tunnels would be made deeper, so as to provide space for additional thickness of insulation, the diameter of the armature being increased to allow of the deeper tunnels.

DESCRIPTION OF THE ELECTRIC ROCK-DRILLING MACHINERY AT THE CARLIN HOW IRONSTONE MINES IN CLEVELAND.*

BY MR. A. L. STEAVENSON, OF DURHAM.

Ironstone mining in Cleveland has now extended over a period of 40 years, during the whole of which the writer has been connected and conversant with its progress.

Mining by Hand Labour. Hand labour has been the general custom, and during the first 25 years, when skilled men were scarce and new comers had to learn the work, it was usual for a skilled miner to take a novice as an underhand with him to break up and fill the stone, paying him a datal wage varying from 3s. 6d. to 4s. per shift. These underhands were known amongst the miners as "hagmen." The skill of the miner being exercised in getting as much stone with as few holes and as little powder as possible, the holes are drilled of a three-cornered section by the miner giving the drill a slight turn between each blow of the hammer; they vary from 3½ft. to 4½ft. in depth, depending upon the backs or natural vertical cleavages in the stone. To drill a hole of 3½ft. requires about half an hour of steady work; the powder used is about 6oz. per ton of stone, and the usual price of getting from 10d. to 1s. per ton. Gradually, as the supply of skilled men overtook the demand, the two miners in each place shared the work and money between them, each man making 4s. 6d to 5s. 6d per shift.

Hand-Ratchet Drill.—During the last few months hand drills made to revolve by a ratchet have been introduced, the work being divided between the skilled miner and the filler. These drills promise good results in cases were machines are not available; but the question of prices is not yet definitely decided.

Compressed-Air Rotary Drill.—About 16 years ago Mr. William Walker, of Saltburn introduced a rotary drill worked by compressed air. Of these the writer procured four; and by working double shift, and employing one skilled man to work the drill and another to fire the shots, with unskilled labour to do the rest, he has effected considerable economy. At the Skelton Park Mines of Messrs Bell Bros. these machines continue doing good work. The writer has always insisted upon the necessity for adopting the Colladon system of cooling the air by water spray during compression; but notwithstanding the marked economy resulting therefrom, the great leakage, arising from the length of pipes of various sizes, which amounts in this case to about eight miles, and from the consequent large number of joints, seemed to present an opportunity for improvement by the use of hydraulic power.

Hydraulic Drill.—At the Lumpsey Mines, therefore, where there was a large body of water tubbed back in the shafts 600ft. deep, the writer designed a hydraulic drill to utilise this water, carrying pipes in to the face of the working places. The pressure of 250lb. per square inch at the shaft bottom was utilised at the drill by means of a small turbine made by Messrs. Gilbert Gilkes and Co., of Kendal, and placed on the machine. This plan has given excellent results; but, as the water has to flow back to the shaft bottom, it can only be used in places to the rise; and moreover it involves the cost of water mains to convey the pressure.

Petroleum Engine.—The writer next introduced the petroleum engine of Messrs. Priestman, and a drill suited to its conditions. Five of these are now in use, and have done good work.

Electric Drill.—When electricity became applicable, its simplicity and regularity in working seemed to offer an inducement for a trial. With the assistance of Mr. Robert Clough, engineer to the mines and collieries of Messrs. Bell Bros., the writer designed a drill to be worked by this power.

Dynamo.—The current for working the drills is generated at bank by a compound wound dynamo, having an output of 20,000 watts, and capable of furnishing a current of 50 amperes at a pressure of 400 volts, when running at 900 revolutions per

* Paper read before the Institution of Mechanical Engineers. Communicated through Sir Lowthian Bell, Bart., Past President.

minute. This dynamo is intended to supply current for working the first section of the plant—namely, three drilling machines. The current required to drive each drill varies, of course, with the hardness of the stone the drill is working in; but it may be taken that under ordinary conditions, and when the voltage at the drills is 300, the current absorbed per drill motor is about 15 amperes, which is about 6 e.h.p.; and when a dynamometer was applied to the drill bar, 6 h.p. was obtained. The current from the dynamo is taken to a high tension double-pole switch on the main switchboard, which is of enamelled slate, and has mounted upon it the necessary fuses, measuring instruments, etc.

Cable and Junction Boxes.—From the switch the current is conveyed down the pit through cables covered with highly vulcanised indiarubber. The cables are run all the way in bye on insulators, and are kept well in sight, so that should a fall of stone occur, the damage can be quickly discovered and set right. The main cables are run to a point at a distance of 1,000 yards from the generator, and then from this point branch cables are run to the different junction-boxes, of which there are six to each drill, commanding 12 working places. The junction boxes were specially designed to meet the exigencies of the case by Mr. Bigge, and are really a combination of a junction box, switch, and connecting plug. The plug is locked in position by a pin, and cannot be withdrawn without first of all lifting the switch, thus preventing sparking and wear on the contacts. Each district to be worked by the several drills is completely wired out and fitted up with these junction-boxes, so that when the drill is moved from one working place to another a box is always to be found within 50 yards distance. The plug at the end of the drill cable is then inserted, the switch on the drill turned on, and within a few seconds the drill is again at work. Much time is saved by this method.

Drilling Machine.—Drawings, half full size, showed that the way in which the electricity is applied is neat and handy. The motor is used not only to drive the drill gear, but also to act as a counter-balance to the weight of the drill itself and its gearing. The motor rotates a shaft, which passes through the long hollow carrying-bar, and by a pair of bevel wheels causes the vertical spindle to revolve; and a bevel pinion on the top of the spindle, gearing into a bevel spurwheel on the boring-bar, rotates the drill. The forward feed of the boring-bar is governed by two pairs of retarding wheels, which are geared in such a proportion as suits the nature of the stone. The drill is carried on a circular bed plate, which is mounted on the end of the carrying-bar and can be turned round by hand when the binding screw is released. As soon as a hole has been drilled the full length of the screw on the boring bar, a split nut is opened, and the boring bar drawn back for inserting a longer drill. In order to reach different heights, the drill can be tilted upwards or downwards by means of a semi-circular arc, which is moved by a worm. By another wormwheel an upright pedestal can be turned horizontally round its centre. A third wormwheel turns the long hollow bar which carries the drill.

Motor.—The motors on the drills are shunt-wound, and can easily utilise a current of 20 amperes at 300 volts pressure, giving off about 95 per cent. of what they receive. They are of the Goolden enclosed kind for mining purposes, both the armature and the commutator being completely enveloped in gun-metal cases, which are both gas and dust tight. Even should water pour over them, or a fall of stone occur, they are perfectly protected, and no appreciable damage would be done them. The brushes used are of special carbon coated with copper. The feed for the brushes as they wear themselves away is automatic, so that they can be run for weeks together without requiring any adjustment or attention. Each drill is provided with a starting switch, placed in the most convenient position on the drill carriage itself, and arranged with resistance coils in such a manner that the drill can be started gradually, and stopped either gradually or instantaneously. Each drill is also provided with a reel of 50 yards of twin flexible cable for the supply and return of the electricity; at the end of the cable is a connecting plug for inserting into the nearest junction box.

Working.—These electric drills were put into the hands of men who had no previous knowledge whatsoever of electricity, and the day the first drill was put into the mine it was at once set to work at the face, and has been at work ever since. The men are now thoroughly accustomed to the drills, and handle them with the greatest ease. The writer has thus tried almost every method for working drilling machines in ironstone mines, including compressed air, hydraulic power, and petroleum engines, and it is his decided opinion, as the result of this practical experience, that for simplicity in working, ease of transport, speed, facility for extensions, and economy in working, the electric drill has proved itself to be in advance of any other mechanical contrivance yet introduced, and that in the future, where power has to be conveyed to any considerable distance for mechanical drilling, electricity will undoubtedly play the predominant part. The entire work was placed in the hands of Messrs. D. Selby Bigge and Co., electrical engineers, of Newcastle-on-Tyne, and Mr. Bigge devoted considerable time with the writer and Mr. Clough to working out and improving the various details of this the first attempt at electric drilling in the Cleveland ironstone mines.

Output.—The joint output for one week for two of the three machines has already reached 1,577 tons with 790 holes. From 80 to 100 holes have frequently been bored by one machine in a shift, each hole averaging about 4½ft. deep. The miners are enabled to earn 7s. 7d. each per shift, while the stone is got at a cost of 7¼d. per ton. Powder is always from one-third to one-half more costly when drilling machines are used than is the case with hand labour, since it suits better to blow the stone out with a larger number of holes which are quickly and cheaply drilled; this plan also makes the stone fall in smaller blocks, and so saves labour in breaking them up previous to filling.

General Results.—In attempting to compare the results obtained with the several drills, the following considerations have to be borne in mind. The conditions of the seam of ironstone affect the output and cost. An open stone admits of fewer holes in one place. Then time is lost in more frequent removals of the drill, and the number of holes drilled per hour is diminished.

The cost of the machine itself sometimes represents the whole and sometimes only a fraction of the total cost. Thus a petroleum drill covers the entire cost of its adoption. But the compressed-air drill in some cases has attached to it an average of more than a mile of pipes, and also requires its engine and compressors, as well as its share of boiler. The electric drill also requires engine and dynamo, with a length of cable depending upon the distance from the shaft; it is still so new that alterations and improvements are being made as experience is gained. The hydraulic drill, although getting its power from natural sources, needs pipes, and the exhaust water has afterwards to be pumped up to the surface. The hand ratchet-drill has been applied as yet in only one or two mines, and the tonnage rates and system of working are not yet finally settled with the workmen.

Subject to these considerations the following comparative statement may be taken to represent generally the results thus far obtained with the several drills.

Description of drill.	First cost of machine only. £	Holes drilled per hour *	Ironstone got per shift. tons.
Hand jumper . . .	— ...	4½ft. in 45min. ..	5 to 8
Hand ratchet drill	3	not yet known ...	about 18
Compressed air drill	250 .	about 8 holes .	100 to 130
Hydraulic turbine . ..	220	„ 8 „ .	100 to 130
Petroleum engine .	375	„ 8 „	100 to 130
Electric drill	350 .	„ 10 „ .	140

* This includes the time lost in moving the machine to different working places.

The length of shift is eight hours from bank to bank, or say seven hours at the face. At the Park Mines the drills work two shifts in 24 hours, and at other mines one shift; and six shifts per week when trade permits.

ON THE ELECTRIC LIGHT OF LIGHTHOUSES.*

EXPERIMENTS MADE BY THE LIGHTHOUSE DEPARTMENT OF FRANCE.

BY ANDRÉ BLONDEL.

(Continued from page 91.)

CONTINUOUS-CURRENT DYNAMOS: THEIR PROPERTIES AND THE RESULTS THEY GIVE.

In order to construct a machine with two fixed *régimes*, say, of 25 and 50 amperes, we may adopt either a winding with two distinct circuits, capable of being used separately or together, or a simple winding, altering the current either by means of the exciting current or by the introduction of a resistance in the circuit. The properties of the machine and the choice of the system to be adopted depend essentially on the method of exciting.

Shunt-Wound Dynamos.—Exciting in shunt is produced, as we know, by the aid of a circuit of fine wire wound on the electro-magnets, and connected either to the brushes or to the terminals of the machine. The shape of the characteristic is in some respects of advantage; on short circuit the intensity, far from becoming dangerous, is reduced to zero; as a consequence there is no pulling up of the motor at starting. But it is difficult to realise in, on normal *régime* the desired slope without approaching too near the limit of demagnetisation; it is then almost a necessity to employ in addition a small rheostat.

A trial of a machine of this type was made at the lighthouse establishment in 1892 with the current of 25 amperes. The working was satisfactory, a rheostat being added; but the machine became

* Paper read before the International Maritime Congress, London meeting, July, 1893.

given by M. Allard* is only applicable to arcs of very small length. It would probably be suitable to the arc light of St. Catherine (Isle of Wight), the separation in which is not more than ½mm., and the pressure only from 35 to 38 volts. With an arc so short, almost always on the point of sticking together, the surfaces of maximum brightness are almost completely shaded by the carbons, and it seems hard to believe that the highest efficiency could be realised in this way, as some have asserted.

In France it is preferred to employ a genuine arc, with a pressure of 45 volts, corresponding to a separation of 4mm. to 5mm. for the current of 25 amperes, and exposing the bright surfaces. The part played as a lighting agent by these is then shown by the curve of light-distribution, which assumes the appearance of a butterfly, Fig. 8, giving maxima in directions having an inclination of 45deg., the superiority of which over the horizontal intensity becomes more marked as the separation is made greater.

Intrinsic Brightness.—It would seem that the maximum intrinsic brightness ought to be less than in the case of the continuous-current arc, since each surface only acts as a positive pole during one alternation in every two, and even less, and can thus cool during the remainder of each period. As a matter of fact, this is the case with arcs of very small activity (8 to 10 amperes). But in those of 25 amperes and upwards, the period of extinction being very short, and each crater being smaller than the average intensity would require, the measurements made with the Le Chatelier pyrophotometer at a frequency of 50 have not shown any appreciable difference. The maximum brightness does not even vary to any extent with the intensity or with the separation. But the same reservations as in the case of the continuous current, must be made as far as the average brightness is concerned.

Practical Effect with Different Currents.—To appreciate the ultimate effect in the optical apparatus, we come back then once more to the question of occultations. The bi-focal arrangement devised by Inspector General Bourdelles, which consists in placing the focus of the dioptric drum, Fig. 9, at the centre of the incandescent part of the lower carbon, and the focus of the catadioptric rings at the centre of the incandescent part of the upper carbon, theoretically allows of nearly all the focal rays of the apparatus, Fig. 9, passing by the surfaces of maximum brightness. But in practice this maximum efficiency is not realised, owing to inevitable occultations, and to an effect analogous to that already pointed out in the case of continuous currents. The power of the pencil still increases with the intensity of the current, as is shown by the following table, which I borrow from the paper already quoted, only adding the column of true efficiencies.†

Diameters of the carbons.	Amperes.	Volts.	Apparent watts.	True watts.	Carcels of 10 candles.	Efficiency per watt.
10	25	45	1,125	1,070	1,200,000	1,120
16	50	45	2,250	2,140	1,800,000	840
25	100	45	4,500	4,275	2,300,000	512

The explanation of this phenomenon might be sought in the same causes as in the case of continuous currents. However that may be, as the luminous power only increases slightly in comparison to the expenditure of energy, there could be no advantage in going farther in this direction, and it would be preferable, in accordance with the curious observation of M. Bourdelles,‡ to unite several lights of small intensity in separate lenses.

However, if we have to employ later on lenses of greater diameters (third, second, and first order), the period of brightness being less than the maximum time of perception,§ all the light would be utilised, and even admitting that the brightness would remain the same, there would be an advantage in increasing, within certain limits, the power of the arc.

(To be continued.)

TRADE NOTES AND NOVELTIES.

STONEWARE CONDUITS.

A new type of conduit for underground mains has been brought out by Messrs. Doulton and Co., and has been on view this and last week at their showrooms, Albert Embankment, Lambeth, S.E. The conduit, which we illustrate herewith, is made of highly vitrified stoneware, and of rectangular and circular form. It is made in lengths of 3ft., and with two or more separate ducts or ways. There are several methods of joining the lengths of casing or conduit: one plan is shown in Fig. 1, which is a cross-section at the joint of a three-way conduit. In this case the ends of the casing when brought together are lapped round with a band of prepared canvas and enclosed in a stoneware trough open at the top. Before being placed in position, the lower interior surface of the trough receives a layer of Portland cement, which cannot enter between the casings owing to the canvas band. The next operation is to fill the trough to its upper edge with cement, and by this means it is possible to rapidly make a reliable joint.

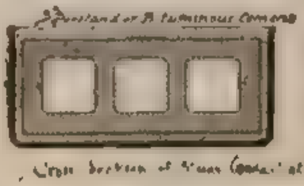

FIG. 1.

In some cases it is necessary to economise space, and under such circumstances another method of jointing may be adopted, as in Fig. 2. This is to substitute a light cast-iron collar or trough for the stoneware trough, adopting the same plan as in the first system, or the trough may be simply filled with bituminous or other cement, the canvas band being also used. For this purpose Messrs. Doulton have prepared a special compound, which forms a very suitable and rapidly-setting cement.

FIG. 2.—Detail of Joint.

The two methods described are sufficient for ordinary requirements, but where it is desired to keep the complete separation of the ducts where the lengths are connected, the joint shown in horizontal section in Fig. 3 may be adopted. According to this arrangement, the lengths of the casing are laid in the collars with a small space between them. Then mandrels with indiarubber heads, as shown in Fig. 4, are introduced in the ducts, and when opposite the joint between the lengths, are expanded by a simple screw arrangement. Molten cement being next poured in, this fills up the space between the casings except where occupied by the mandrels. The cement sets in two or three minutes, and the mandrels are then unscrewed and withdrawn. This plan enables each duct to be kept entirely separate and continuous with a uniform section throughout the whole length of the conduit. This stoneware conduit possesses great strength, tests showing in the case of the rectangular section that it only cracked at 25 tons to the square foot. It is claimed that this type of conduit affords a perfect mechanical protection to insulated cables, that the material is imperishable, and that it is cheap. Messrs. Doulton also show stoneware tubes provided with self-fitting watertight joints, the arrangement being the use of bitumen cast on to the ends of the pipes; also connection boxes as used at Derby and Whitehaven, and improved insulators for bare copper mains. These insulators, instead of being moulded and made separately, are pressed through a die and cut up in lengths, and have been adopted at Oldham and Aberdeen.

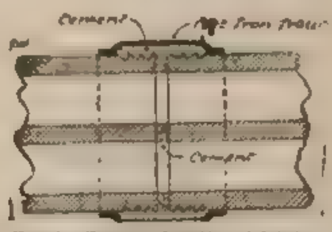

FIG. 3.—Horizontal Section at Joint.

CROMPTON AND CO.

Our financial contemporary, the *Financial Times*, has an article in yesterday's issue entitled "Electric Darkness," criticising a letter sent by the secretary of Messrs. Crompton and Co. in reply to a correspondent. We are not much concerned with the statements in this article, because, if necessary, the whole criticism can be shown to be of the very flimsiest description. If the *Financial Times* desired to criticise a balance-sheet it might do so in the ordinary manner and not through a reply to a correspondent. Mr. Reeves can take care of himself without our aid, but there is a principle behind this action with which we wish to deal. Our reading of the *Financial Times* may be wrong, but its action seems to us to be this: A friend of the paper—whether really an intending investor or not; we imagine not—writes to the secretary of the company before the balance-sheet is out, asking for information in view of investment. Our interpretation is that the authorities of the paper wanted to elicit some information for their own purposes, and not for the purposes of a *bonâ fide* investor, and took this round-about-way of obtaining it, instead of going straight to the mark themselves, where they would have got either a positive or a negative quantity of information. This round-about action, if it exists, puts a secretary into a queer position. He may desire to give a *bonâ fide* investor all possible information, thinking it is information given from man to man, and not intended to be used or seen by third parties. In the particular case under discussion, the secretary referred to the probability of the balance-sheet being somewhat similar to that of the preceding twelve months, but it turned out that there were differences to which the *Financial Times* is not slow to call attention. The reply of the secretary that there had been a large abnormal expenditure during the year, and at the time he wrote it was under discussion to deal with this expenditure in one way while subsequently it was dealt with in another, is a perfect answer to the adverse criticism that he ought to have known at the beginning of July how the accounts ending March 31 stood. He did not know, and yet he did know—that is, he knew the totals, but not the method of disposal, a question the directors had not decided. Was the secretary for the benefit of a fishing correspondent—as proved by the remarks in the *Financial Times*—to give in detail the items of the accounts as made up to March 31, explaining that there had been abnormal expenditure and how it had to be treated was not then settled, or was he to reply to the correspondent in a general way, as in fact he did? Time has shown—at least we think time and the action of the financial critic has shown—that if Mr. Reeves had in confidence given the exact figures at his hand, they would have been used for financial newspaper purposes, and not confidentially by the recipient. There is another point in this critic's lucubration we should like to be noticed—his reference to "ordinary shares" and their treatment in the balance-sheet. What had Mr. Reeves' communication to do with this? He was asked about investing in preference

shares, and, in reference thereto, said, "the report will, I believe, be of a similar nature"—that is, similar to last year—and no doubt had the directors thought well to deal differently with the abnormal expenditure the report would have been similar. Our view of the case is this, that if financial papers want information let them get it in a straightforward manner, and not use ordinary correspondence for their peculiar purposes. Secretaries of companies ought not to be compelled to think before writing letters that the contents may be used for newspaper work, and we will go further, and say that newspapers of any reputation whatever ought to be above using the contents of private letters for their work. In this present case the criticism in this particular direction seems doubly unfortunate. Directors as a rule are not too eager to saddle any one year's revenue with extra expenditure, and if possible will put it to capital account or suspense account, or anywhere not to interfere with the dividend. In this instance the directors took a wiser course and paid the account out of revenue. We think they were right, and commend them for so doing, because we think the concern has more than enough capital to provide dividends for already. If we were to criticise the balance-sheet it would be to argue the general point that no preference shares or debenture stock ought in any concern to carry more than 5 per cent. In reply to this we should be told: you won't get money for any concern under such conditions. Rubbish! Now, as heretofore, most investments for higher dividends than 5 per cent. are risky. This very balance-sheet shows that under ordinary conditions at least 5 per cent. on £275,000 is and can easily be earned, and the path of directors would be smoother if that were the goal rather than a higher percentage on the greater part of the capital and none on the remainder.

EDISON-SWAN.

The balance-sheet of this company given in our last issue, and the report of the meeting as given in our issue to-day, form perhaps the most interesting company history of the year. The chairman directed his attention partly to the future. The period of competition is coming along, patents are about to expire, and it becomes important to the shareholders to ascertain how much, if any, their business will be affected. Our contention with regard to all companies purchasing and working patents is that by law they have given them a close period during which there is no competition, and during which, if the patents are worth anything, a business can be established. An established business is valuable, the value being expressed as good will. A rightly-conducted concern when the patents lapse should have a goodwill as valuable as the cost of the patents, or, rather, as valuable as the amount they stand for in the balance-sheet at the expiration of the patents. The crux of this balance-sheet is the item £242,244—cost of patents, etc. Can this amount in future be charged against goodwill? We think not. It is too high, especially as there is a deferred amount of £117,800 to the same account. Mr. Edison and his colleagues have not taken much out of this company for their nominal holding, they participate in the current distribution of profit, and this is the first time they have participated. The chairman, in his remarks, was cautious in promising participation in future profits by these shares. He hopes they will, but the directors first look to other shareholders. What is the outlook? Throughout the length and breadth of the land travellers for continental firms are offering lamps at 1s. each, as against the 3s. 9d. charged by the Edison-Swan Company. If the company has to reduce its price to a similar amount, its income must be enormously decreased, for we certainly shall not have a sufficient increase in the consumption during the next year to make up for this huge drop. Of course, most people know that the company still controls certain patents relating to holders which makes their position far stronger than if they were wholly dependent upon the lamp patents. Still, with all their advantages, the outlook is far from pleasant, though we agree that within a few years the use of lamps will enormously increase. There is one point to be considered which is generally overlooked that may tell in favour of the company. It is almost certain that no incandescent lamp is made according to patent specification. Improvements in manufacture have been made, and the experience of manufacture should give this company a great pull over their rivals. The lamps offered at these cheap rates have not been tried, and when tried may be found wanting, so that trustworthy lamps will still fetch a higher price, and be eagerly sought after. There are probably some trade secrets not embodied in patents which tend to the making of the better article. It remains to be seen then what the ultimate effect on prices may be.

ON LIGHT AND OTHER HIGH-FREQUENCY PHENOMENA.*

BY NIKOLA TESLA.

(Continued from page 85.)

In these experiments the gas acts in two opposite ways in determining the degree of the incandescence of the filaments—that is, by convection and bombardment. The higher the frequency and potential of the currents, the more important becomes the bombardment. The convection, on the contrary, should be the smaller, the higher the frequency. When the currents are steady, there is practically no bombardment, and convection may therefore with such currents also considerably modify the degree of incandescence and produce results similar to those just before shown. Thus, if two lamps exactly alike, one exhausted and one not exhausted, are connected in multiple arc or series to a direct current machine, the filament in the non exhausted lamp will require a considerably greater current to be rendered incandescent. The result is entirely due to convection, and the effect is the more prominent the thinner the filament. Prof. Ayrton and Mr. Kilgour some time ago published quantitative results concerning the thermal emissivity by radiation and convection in which the effect of thin wires was clearly shown. This effect may be strikingly illustrated by preparing a number of small short glass tubes, each containing through its axis the thinnest obtainable platinum wire. If these tubes be highly exhausted, a number of them may be connected in multiple arc to a direct current machine, and all of the wires may be kept at incandescence with a smaller current than that required to render incandescent a single one of the wires

* A lecture delivered before the Franklin Institute, at Philadelphia, February 24, 1893; and before the National Electric Light Association, at St. Louis, Mo., March 1, 1893.

if the tube be not exhausted. Could the tubes be so highly exhausted that convection would be nil, then the relative amounts of heat given off by convection and radiation could be determined without the difficulties attending thermal quantitative measurements. If a source of electric impulses of high frequency and very high potential is employed, a still greater number of the tubes may be taken, and the wires rendered incandescent by a current not capable of warming perceptibly a wire of the same size immersed in air at ordinary pressure, and conveying the energy to all of them.

I may here describe a result which is still more interesting, and to which I have been led by the observation of these phenomena. I noted that small differences in the density of the air produced a considerable difference in the degree of incandescence of the wires, and I thought that, since in a tube through which a luminous discharge is passed the gas is generally not of uniform density, a very thin wire contained in the tube might be rendered incandescent at certain places of smaller density of the gas, while it would remain dark at the places of greater density, where the convection would be greater and the bombardment less intense. Accordingly a tube, t, was prepared, as illustrated in Fig. 23, which contained through the middle a very fine platinum wire, w. The tube was exhausted to a moderate degree, and it was found that when it was attached to the terminal of a high frequency coil the platinum wire, w, would, indeed, become incandescent in patches, as illustrated in Fig. 23. Later, a number of these tubes with one or more wires were prepared each showing this result. The effect was best noted when the striated discharge occurred in the tube, but was also produced when the striæ were not visible, showing that even then the gas in the tube was not of uniform density. The position of the striæ was generally such that the rarefactions corresponded to the places of incandescence or greater

FIG. 23.—Curious Incandescence of a Wire.

Utilising the Heating Effect of Conduction Current and Bombardment.

brightness on the wire, w. But in a few instances it was noted that the bright spots on the wire were covered by the dense parts of the striated discharge, as indicated by l in Fig. 23, though the effect was barely perceptible. This was explained in a plausible way by assuming that the convection was not widely different in the dense and rarefied places of the striated discharge. It is, in fact, often observed in bulbs that, under certain conditions, a thin wire is brought to higher incandescence when the air is not too highly rarefied. This is the case when the potential of the coil is not high enough for the vacuum, but the result may be attributed to many different causes. In all cases this curious phenomenon of incandescence disappears when the tube, or rather the wire, acquires throughout a uniform temperature.

Disregarding now the modifying effect of convection, there are then two distinct causes which determine the incandescence of a wire or filament with varying currents—that is, conduction current and bombardment. With steady currents we have to deal only with the former of these two causes, and the heating effect is a minimum, since the resistance is least to steady flow. When the current is a varying one, the resistance is greater, and hence the heating effect is increased. Thus, if the rate of change of the current is very great, the resistance may increase to such an extent that the filament is brought to incandescence with inappreciable currents, and we are able to take a short and thick block of carbon or other material and bring it to bright incandescence with a current incomparably smaller than that required to bring to the same degree of incandescence an ordinary thin lamp filament with a steady or low frequency current. This result is important, and illustrates how rapidly our views on these subjects are changing, and how quickly our field of knowledge is extending. In the art of incandescent lighting, to view this result in one aspect only, it has been commonly considered as an essential requirement for practical success that the lamp filament should be thin and of high resistance. But now we know that the resistance of the steady flow of the filament does not mean anything; the filament might as well be short and thick, for if it be immersed in rarefied gas it will become incandescent by the passage of a small current. It all depends on the frequency and potential of the currents. We may conclude from this that it would be of advantage, so far as the lamp is considered, to employ high frequencies for lighting, as they allow the use of short and thick filaments and smaller currents.

If a wire or filament be immersed in a homogeneous medium, all the heating is due to true conduction current, but if it be enclosed in an exhausted vessel the conditions are entirely different. Here the gas begins to act and the heating effect of the conduction current, as is shown in many experiments, may be very small compared with that of the bombardment. This is especially the case if the circuit is not closed, and the potentials, of course, very high. Suppose a fine filament enclosed in an exhausted vessel be connected with one of its ends to the terminal of a high tension coil and with its other end to a large insulated plate. Though the circuit is not closed, the filament, as I have before shown, is brought to incandescence. If the frequency and potential be comparatively low, the filament is heated by the current passing through it. If the frequency and potential, and principally the latter, be increased, the insulated plate need be but very small, or may be done away with entirely; still, the filament will become incandescent, practically all the heating being then due to the bombardment. A practical way of combining both the effects of conduction current and bombardment is illustrated in Fig. 24, in which an ordinary lamp is shown provided with a very thin filament, which has one of the ends of the latter connected to a shade serving the purpose of the insulated plate, and the other end to the terminal of a high-tension source. It should not be thought that only rarefied gas is an important

Illustrating Lateral Diffusion.

Incandescence of a Solid

factor in the heating of a conductor by varying currents, but gas at ordinary pressure may become important if the potential difference and frequency of the currents is excessive. On this subject I have already stated that when a conductor is fused by a stroke of lightning, the current through it may be exceedingly small, not even sufficient to heat the conductor perceptibly, were the latter immersed in a homogeneous medium.

From the preceding it is clear that when a conductor of high resistance is connected to the terminals of a source of high-frequency currents of high potential there may occur considerable dissipation of energy, principally on the ends of the conductor, in consequence of the action of the gas surrounding the conductor. Owing to this, the current through a section of the conductor at a point midway between its ends may be much smaller than through a section near the ends. Furthermore, the current passes principally through the outer portions of the conductor, but this effect is to be distinguished from the skin effect as ordinarily interpreted, for the latter would or should occur also in a continuous incompressible medium. If a great many incandescent lamps are connected in series to a source of such currents the lamps at the ends may burn brightly, whereas those in the middle may remain entirely dark. This is due principally to bombardment, as before stated. But even if the currents be steady, provided the difference of potential be very great, the lamps at the ends will burn more brightly than those in the middle. In such case there is no rhythmical bombardment and the result is produced entirely by leakage. This leakage or dissipation into space when the tension is high is considerable when incandescent lamps are used, and still more considerable with arcs, for the latter act like flames. Generally, of course, the dissipation is much smaller with steady than with varying currents.

I have contrived an experiment which illustrates in an interest-

tea, provided by Messrs. Johnson Bros., New-street, was then partaken of in the committee room, the engines meanwhile running slowly. After tea the electricians switched the alternators on to the omnibus bars at the station, and shortly before a quarter past seven o'clock Councillor Garton, chairman of the committee, and Councillor Marshall, vice-chairman, having taken up positions by the circuit boards, respectively switched on the No. 1 and No. 2 circuits amid applause, the lights in the town being immediately started. Five minutes afterwards a telephone message was received to the effect that the lights in the Town Hall, the Market Hall and the main streets were burning steadily. The station itself is lighted by means of arc and incandescent lamps. The wiring is by Mr. Alfred Sykes, of Turnbridge, Huddersfield.

Mr A. B. Mountain gave an account of the Corporation's undertaking for supplying electric light, in which he stated most of the facts given above. In concluding he observed that it would, of course, be understood that in the interests of the undertaking it was very desirable to have as many consumers as possible connected with the mains, so that the machinery, when running, would be supplying some considerable quantity of light. The mains had been so laid in the centre of the town that any consumers could be reached by very slight extension of the mains, and it was hoped now that the light could be seen and its good qualities admired, those who had been hesitating would send in their applications immediately.

Councillor Garton presided in the committee room at a convivial ceremonial after the inauguration, and thanked those present for their attendance. **Councillor Marshall** also spoke, as did **Alderman Glendinning** and **Alderman Haigh**, while the **Mayor** proposed the "Contractors," to which toast **Mr Mordey** responded, observing that as far as the Brush Electrical Engineering Company was concerned, it was in a very satisfactory state. It was not the first opportunity he had had of meeting members of that committee. Nearly two years ago he was at Bournemouth, when the committee, who were going throughout the country, came there, and he remembered that so many questions were put to him that he was nearly exhausted with answering them. He had been asked to speak a few words with regard to the commercial prospects of electric lighting. The subject was such a wide one that he could take a whole evening in dealing with it. He proposed to speak not on the engineering, but on the general prospects of electric lighting especially in a case like theirs. He believed they had that day inaugurated what was bound to be a successful commercial undertaking, as well as a successful engineering one. Alderman Haigh had alluded to the fact that at certain places the committee called they were not able to get a direct answer in the affirmative as to whether the works paid a dividend or not. He was afraid that was true, but it must be remembered that in many cases the people to whom the question was put were the pioneers. In Huddersfield they had the advantage of benefiting by others' experience. The plant they had put down and adopted had been fully tried; everything that was weak or wrong had been eliminated, and they had the kind of plant that would give the most efficient results in every way, and give the least trouble to the people who had to work it. He thought that the success of the undertaking would not be delayed very long. As to the cost of working he understood they had arranged to charge 6d. per unit. There was a great deal of confusion some times as to what a unit was. He believed that in Huddersfield gas was 3s. a 1,000. If that was so, then they would get as much electric light for 3s. as they got gas light; that was to say, electricity at 6d. a unit was equivalent in light-giving power to gas at 3s. a 1,000. They saw, therefore, that instead of electric light being a dear light, it was practically the same price as they were paying for their gas. Of course there were many advantages connected with electricity, such as coolness and healthfulness, and the decorations of houses were not affected at all, as they were by gas. He believed the adoption of the electric light would lower the death rate. Then people were finding that they could use underground premises by adapting electric light which would otherwise be useless. He was not an opponent of gas, on the contrary, he was a believer in it, not, however, for lighting, but for heating and cooking and power. He thought there ought not to be 10,000 little places, each sending out its little column of smoke, but that all coal should be collected in one place and the fuel supplied in the form of gas. The gas engine, he believed, was the engine of the future. Nothing even now could compete with gas for a small engine. For running factories and for regular work from six in the morning to six or seven at night, he did not think it would ever pay to supply power by electricity, simply because a horse-power cost 6d., a unit being equal to about 1 h.p. At Newcastle, where Mr. Mountain had been schooled—and in Mr. Mountain they had a gentleman who had had a great deal of experience—electricity was supplied at a lower rate than any other station in the country or the world. With plant which he (the speaker) designed they were producing energy at the rate of 2½d. per unit, and were selling it at 4½d., actually bringing the sale price with discount down to 4d. At this price it was paying, and paying well. He believed that Mr. Mountain would do better in Huddersfield, because for one thing he had better engines. Then they had water for condensing, and cheaper coal, and as they had customers he thought there was no doubt whatever that the undertaking would be a sound commercial one from the very commencement. The plant was arranged in such a way that they could always work it most economically. He could congratulate the committee on the result of its labours as to the choice of a system, although his company manufactured a large quantity of low tension plant as well as high. Engineers were all coming round to the view that to get over long distances they must have high tension. In Huddersfield they were able to run to Edgerton, about two miles, whereas in Bradford they were absolutely limited by the low tension to a few hundred yards. In conclusion, he had to thank his colleagues, Mr. Mahood for carrying out the work of erecting the machinery, and also Mr. Geipel who was responsible for the engineering of such plant, and Mr. Raworth, the chief engineer of the company. As neither of the latter two could be present, he had come that evening on their behalf.

Alderman Brigg proposed the health of their chief engineer, Mr. Mountain. He referred to the fact that Mr. Mountain was a young man, and remarked that the ability he had displayed in carrying out the work so far must have surprised everyone.

Mr Mountain thanked the company for the way in which they had drunk his health. The work had been a very great pleasure, and he had every confidence that the undertaking would be a success.

COMPANIES' MEETINGS.

EDISON AND SWAN UNITED ELECTRIC LIGHTING COMPANY, LIMITED.

The tenth annual meeting of the shareholders took place on Friday last at the City Terminus Hotel, E.C., under the presidency of Mr. J. Staats Forbes (chairman). The secretary (Mr. H. C. Gover) read the notice calling the meeting, and the report was taken as read.

The **Chairman**, in moving the adoption of the report, said: I think the essential part of the report is in a nutshell, and it is embraced in this—that the gross receipts of the year are the largest the Company has ever obtained, the expenses are exactly in the same description, for reasons which I will presently more explain, and the net profit for the year has been increased by £11,832. The position of the Company is, as you know, approaching a moment when there will be a considerable change—the period of protection will expire in November, and we should have been very much failing in our duty to you if we had not anticipated that period for some years. We have been working on a well-considered design for a number of years, the design being that when we emerge from protection we shall be prepared for competition. I daresay we shall have some. This is the tenth complete year of our existence, and it is worth while calling your attention to the fact that in the first five years we paid no dividend at all, and we began the sixth year with an enormous incubus in the shape of the cumulative claim of the "A" shareholders—£121,000 in round figures. During the five succeeding years electric lighting extended somewhat rapidly in comparison with the earlier years, and we have been able not only to pay the 7 per cent. preferential dividend secured to the "A" shareholders, but to wipe off that considerable amount of £121,000; so that, in fact, we emerge from the protected period, having paid 7 per cent. for the whole of the 10 years, and as regards this present year, with the addition of 3 per cent. out of the profits. The balance of profit, you will see on turning to the profit and loss account, amounts to £86,642, and you will also see how we propose to appropriate it. When we began the year, the balance of arrears on the cumulative "A" shares amounted to £8,261—that was the last remnant of the £121,000 which we began with five years ago. That, of course, had to be got rid of, and it was done by an interim payment at the end of the first six months, in addition to which we paid 3½ per cent. for the half year ended December 31—£12,371—on the "A" shares. Now we propose to make up the 7 per cent. preference dividend which the "A" shares are entitled to and, for the first time in our history, the position of the "B" shares is to be taken into account in regard to dividend. This £117,000 worth of shares represents the interest of Mr. Edison and his friends as the purchase price of the patents and the founding expenses of the Edison Company, and is held subject to this—that they participate to the extent of one-fourth in any profit of the undertaking after we have satisfied the 7 per cent. preference claims of the "A" shares. I hope the participation of the "B" shares in our profits will endure. We carry over the very considerable sum of £39,148; but seeing what is before us, we think we should have a strong reserve, and the Directors have had no hesitation in what they conceive to be their duty to you in recommending a 10 per cent. dividend, instead of one which of course, was possible if we had trenched further on the profit of the year. What we have to consider is whether the profit of the year, as represented in these figures is likely to be maintained in face of the competition which, at all events, may be tolerably severe. We shall not escape the inevitable, and must endeavour to hold our own. We think that with our good organisation, a large connection, strong reserve, and a good name we shall be able, if not to see such large results as during the protected time, at all events to retain sufficient business to make the dividend a very fair and reasonable one. What it will be no man can tell; but what I do know is that we shall have to keep our eyes open and put our best foot forward in the next two or three years. With that view we have become manufacturers as well as lamp makers. For a very long time we were so bitten by the errors of the two companies—the Edison and the Swan—in entering upon installation business and contracting for supplies of light and so forth, that we determined not to touch that work until we saw our way very clearly; therefore, for a number of years we pursued the humble rôle of lamp makers. Latterly we have merged into the business of manufacturers of appliances for fitting and installation in houses and elsewhere, and although the lamp patents expire in November, we have other

valuable patents in connection with the appliances which are already bringing in a considerable annual income, and which extend over a tolerably long term of years. In respect of these patents, for holders and so forth, we have continued to manufacture them for ourselves, and charged ourselves the same royalty as we charge our licensees and we have licensed a large number of leading firms in the gasfitting, lampfitting, and brassfounding business who are competing with us in the sense that they are bound to sell at the same price as we do, and are paying us a royalty. Of course, this business is of the character of many others; the fixed charges are considerable, and are not influenced by the number of lamps sold. The price of the lamp is ear marked, and you can produce a large number at a rate per lamp considerably less than a smaller number, and we have attained that position in which we can produce lamps as cheaply, certainly as anyone in this country, probably in Europe. The reputation of the lamp seems to be established. I daresay when the competition comes on us we shall have lamps from all parts, Germany and the Continent generally. We know pretty well what those lamps are, and have a knowledge which enables us to measure possibilities, and although, no doubt, the number of lamps sold may in the first moment of this competition be affected, more or less, we must look to the general development of the business, and to our being able to hold our own in the total output of lamps, which must, year by year, greatly increase, because only quite recently the electric light business seems to have improved. One has the opportunity of reading in the papers the speeches of gentlemen connected with electric lighting companies, and we have been interested to learn in that way how the Westminster, the St. James's, the Metropolitan and other companies have all largely increased the number of their lights. All this means the rapid multiplication of lamps. When the time comes we must endeavour to hold our own relatively to the general advance in this business, which I believe I can foresee will be considerable during the next few years. There is another thing to which I should like to call your attention. The gross income, including the stock, you will see is £240,271, as against £212,048 last year, an increase of £28,223. The gross expenses have been £153,629, compared with £137,236, or more by £16,393, leaving a net profit of £11,831 in addition to that of last year. That £16,000 is rather a large increase in the expenditure, but this year, for the first time, we have had to bear the burden of the establishment of a number of depots. As our business extends, people who live in the great centres of industry will probably get tired of drawing their supplies from the factory at Ponder's End, therefore we were determined to try the experiment of a London depot, and we opened one in Parliament street, Westminster, where we have done an extremely good business. We have also opened another at 110, Cannon street, with like satisfactory results. In addition to the two depots in London, we have opened one each at Birmingham, Cardiff, Liverpool, Leeds, Newcastle, Hull, Dundee, Glasgow, Belfast, and Dublin, and we are doing business in all those places. Now, I should like to say a few words with reference to our solid asset, and by that I mean our tangible property. The preferred or "A" capital of the company is £353,478, which has a cumulative claim of 7 per cent. before the "B" capital gets anything. It takes £24,743 to pay that 7 per cent. Our capital is £353,478 of subscribed money and £117,820 in deferred shares, in virtue of the benefits accruing from our patents. As, however, these patents are on the point of expiring, not much value can be attached to them for the future; but, as far as the holders of that £117,820 go, they are entitled to a quarter of anything over 7 per cent. on the "A" shares. I hope they will get their quarter, and I think there is a probability that they will get something. But we are more concerned for the people who found the £353,478. Now of that amount we have got a solid asset in the nature of freehold property, plant and stock, debtors, and consols to the extent of £200,000. Of course, that is the value as a going concern; but we have written off these items considerable sums from year to year. We have, then £200,000 and the question now is whether our experience, our capacity to supply the demand, and our trade mark, is worth the balance. You are as capable of judging that as I am. I am sanguine enough to believe it is, and I think we need be under little apprehension that our venture will continue to be certainly a reasonably profitable one, and probably a very profitable one, because, with the extension in the number of lamps sold, we shall speedily retrieve the loss which may ensue upon the sale price of them, when we emerge from the protected period. I do not know whether anyone will be curious upon the subject of accounts; if so, I shall be happy to enlarge upon them. But I think they speak for themselves. I now move the adoption of the report.

Major S. Flood Page (deputy-chairman) seconded the motion, which was adopted.

The **Chairman** next moved: "That a dividend be and is hereby declared on the A shares of the Company of 4s. 0½d. per share on the 89,261 ordinary, £3 paid; of 6s. 8¾d. per share on the 5,000 £5 fully paid shares allotted to the Edison Electric Light Company, Limited; of 5s. 0½d. per share on the 12,139 £5 fully paid shares allotted to the Swan United Electric Light Company, Limited; and of 3s. 2d. per share on the B shares of the Company, being, with the interim dividend paid on March 14, 1893, a payment on the A shares of the Company of the balance of arrears of cumulative preferential dividend, and of 10 per cent. in respect of the year ending June 30, 1893; and on the B shares of the Company 3 per cent. in respect of the year ending June 30, 1893. All to be distributed in accordance with the provisions of clause 87 of the articles of association, income tax free."

This was seconded by **Major Flood Page**, and was unanimously carried.

Mr. Killingworth Hedges referred to negotiations proceeding for an amalgamation of the Swan United Company with this Company, and he should like to hear if there were any chance of the interest of the two companies being brought together. He should like to know whether such an amalgamation would lead to economies being effected.

The **Chairman** said the Board had felt the importance of that amalgamation from year to year, and it had become accentuated as the period of the expiration of the patents approached; therefore, they had given their attention to the subject during the year. A proposition had been formulated, and, substantially, he understood — for, being chairman of both companies, he had stood out of the negotiations — agreed upon, upon which the Edison and Swan would take over the remnant of the business of the Swan Company. There were one or two internal matters which would, however, have to be submitted to the shareholders of both companies before the amalgamation could be carried out. One of the objects of the fusion would certainly be to promote economy of administration.

On the motion of the **Chairman**, seconded by **Mr. Hedges**, Major Flood Page was unanimously re-elected to his seat on the Board, and Mr. Shelford Bidwell, F.R.S., was similarly reappointed, on the motion of the **Chairman**, seconded by **Mr. Cuthbert Quilter, M.P.**

Messrs. Welton, Jones, and Co. were reappointed the auditors, and the proceedings were then brought to a close.

CITY AND SOUTH LONDON RAILWAY COMPANY, LIMITED.

The eighteenth ordinary general meeting was held on Tuesday at Winchester House, E.C., Mr. C. G. Mott (chairman) presiding.

The Secretary (Mr. W. F. Knight) read the notice convening the meeting, and the report was taken as read.

The **Chairman** said it became his duty to move the adoption of the report and accounts. In doing so, he stated that they would be pleased to see that the steady increase in the Company's receipts had continued during the past half year, in spite of the lengthy spell of hot weather which was generally detrimental to the traffic of the line. On the other hand, there had been no increase in the expenditure, but, on the contrary, a small decrease, which was a very satisfactory condition for any company to be in. The Board had again to report that the line had been worked with the greatest regularity, and without any stoppage or detriment whatever. The line itself, he thought, was growing in popularity with the public, who found that it had an almost unexampled regularity of service, perfect punctuality, and a pure atmosphere, free from all noxious vapours, that there was an even temperature, which was pleasant both in summer and winter, and that altogether the line was such as was very much wanted in the metropolis, and was a very great improvement upon all other existing railway communication. Referring to the accounts, the Chairman said they had raised during the half year £17,050 on capital account, this having been used in paying off liabilities amounting to £10,209, and in expenditure on the Stockwell sidings, and various other matters, to the extent of £6,181. They had paid off in the same period £3,800 of the terminal debentures, and had replaced them with 4 per cent. debenture stock, issued at a premium, so that a small saving had been effected in that respect. The amount of debentures falling due that half year was exceptionally small, but in the future the amount would be larger, and they would thus derive an increased benefit and more saving each half year, until they got the whole of those debentures paid off and converted. The receipts from passengers had increased by £1,491, and those from season tickets by £86; in fact, in every department of the receipts there had been an increase, making the total advance for the half year £1,639. The expenses for maintenance had increased by £13, locomotive expenses had decreased by £159, carriage repairs as might be expected had increased by £57, and the traffic expenses showed a decrease of £124. The general charges had increased by £160, this being chiefly due to their having insured against accidents. Although their liability for accidents was exceedingly small, the Board thought it desirable that in the early stages of the railway they should run no risk which might interfere with the dividends. They insured for a considerable amount by paying £200 a year, and he hoped the accident company would reap the benefit, and that this Company might never have to make a claim upon them. He thought the shareholders would agree that this was a wise and prudent course to adopt. Then they had had to pay £24 for passenger duty, which had not appeared in previous half years. The matter had been under discussion with the Inland Revenue authorities for several years, because owing to the fact that they did not issue tickets and that they gave their passengers the right to travel over the whole length of the line, the Company's contention was that they had no means of knowing how far the passengers travelled, and that, that being the case, they were not liable to duty, because the charge came to less than 1d. per mile. The authorities, on the other hand, contended that a certain number of passengers did not travel a sufficient distance to make the rate 1d. per mile. As it was impossible to obtain precise information on the point, a compromise was agreed upon, and the Company consented to pay passenger duty to the extent of £24 as what was due for the past year and one or two previous half years. Law charges had decreased by £32, rates and taxes had increased by £44, and compensation had decreased by £117, the result being a decrease of £134 in the expenditure, making, with the larger receipts, a net increase in the revenue of £1,773. As to the rates and taxes the increase had been going on steadily, and he thought they must look forward to

its continuance. Concerning the percentage of working expenses, in their first half year their expenses were 79 per cent. of the receipts; in the second, 76 per cent.; in the third, 70 per cent; in the fourth, 67·9 per cent.; and last half year, 64·6 per cent. It would thus be seen that there had been a steady, regular decrease in the percentage, and he hoped that would continue until the expenses were cut down to a much lower rate than at the present time. This calculation included the item of lifts, which was an expense not connected with other railway companies. Deducting the cost of working those lifts, their percentage would be 56½, which was very nearly the same as that of many of the larger railway companies. The changes which had taken place in the receipts per train mile were interesting. In the first year the figure was 2s. 1d; in the second, 2s. 1½d; in the third, 2s. 2½d; in the fourth they increased the mileage to a large extent, and the receipts consequently fell to 2s. 0½d per train mile. Last half year, as compared with the December half, they had only made a very small addition to the mileage, and the result had been that they were overtaking the large addition of train mileage, and that the receipts per train mile had risen to 2s. 1½d. The expenses per train mile had been, in the first half year, 1s 9½d; in the second, 1s. 7½d; third, 1s. 7¼d.; fourth, 1s. 5½d; last half year, 1s. 4½d. This was a very satisfactory feature. The locomotive expenses per train mile had been: First half year, 9d.; second, 7·9d; third 7·7d; fourth, 7·1d.; last half year, 6·18d. If they compared those figures with the locomotive expenses of the large railways of England, they must deduct the carriage of the coal, which this Company paid, and which the others did not. Making that deduction, the locomotive expenses per train mile would be reduced to 5½d. for the past half year, which was very little more than half the rate which it cost the large railway companies for steam purposes. The receipts per passenger had been: In the first half year, 1·90d; second, 1·70d.; third, 1·73d.; fourth, 1·60d; and last half year, 1·66d. Those variations were mostly in consequence of the increase or decrease of the local short passenger traffic. A year ago they tried in various ways to get for a mid day traffic a number of short distance passengers at low fares, and they were successful in so doing, but the result was that although they had a general increase in the receipts, it diminished the receipts per passenger from 1·70d. to 1·60d. Last half-year they had a general increase in the longer distance traffic, and the figure had risen to 1·66d, or very nearly the same as before they made the reduction. The new sidings at Stockwell were practically completed, and would be very shortly brought into use. The Directors were anxious to have them in use before the winter traffic commenced. He thought they would enable the company to improve the service during the winter. By putting in an additional signal station between Stockwell and the Oval they had been able to improve the service somewhat during the past half year. The Company's Bill for the extension to Islington had passed the House of Lords. It had to go down to the Commons for consent to certain alterations, and would then only await the Royal assent. The Board were anxious to improve the King William-street Station at the surface, which was dark and confined at present, and was rendered difficult to improve owing to the small space available. They had an opportunity of acquiring the lease of the adjoining property at a very moderate price, and they had obtained that lease, so that they were now considering what alterations they could make at a small expenditure in the way of improving the access at the top of that station. He then moved the adoption of the report and accounts.

Mr. C. Seymour Grenfell seconded the resolution, which, on being put, was carried without any discussion.

The **Chairman** then moved, and **Mr. Sampson Hanbury** seconded, that a dividend at the rate of 5 per cent. per annum on the preference shares be declared. This was adopted, and a dividend at the rate of ¾ per cent. per annum on the consolidated ordinary stock was also declared.

A hearty vote of thanks was passed to the Chairman and other Directors, and the former, in reply, expressed his complete confidence in the future of the undertaking.

CROMPTON AND CO., LIMITED

The fifth annual general meeting took place at the Cannon street Hotel on Monday, under the presidency of Viscount Emlyn, chairman.

The secretary, Mr. F. R. Reeves, read the notice convening the meeting, and the report was taken as read.

The **Chairman** before putting the first resolution, said that although the Directors met the shareholders with a diminished dividend, he was justified in congratulating them on the progress and position of the Company. The turnover of business showed a satisfactory increase over that of the previous year, and the gross receipts on trading exhibited an increase of nearly £3,800. That progress has been made in spite of the severe commercial depression which had, more or less, affected all classes of business, and consequently checked the receipt of orders for their goods. Australia had formerly been a large customer to them, but during the year very little had been done with that country. There were, however, signs that that trade was likely to improve. The orders booked in the last three months had very nearly equalled those in the whole of the previous year, and the outlook from South Africa was promising. The cost of manufacturing goods at the Chelmsford works had again been considerably reduced, and as far as economy was concerned, the Directors had every reason to be satisfied with the progress made in this direction. Unfortunately some exceptional and unforeseen expenses had had to be borne, the principal of which were those attending the temporary arrangements consequent upon the breakdown of the boilers at the works. The water supply there was both expensive and unsatisfactory in quality, and the boilers, when the heavy pressure of the town lighting came on last winter, gave out, and before new ones could be obtained, temporary boilers had to be hired and put into position at great expense. Since then, however, new boilers and pumping plant had been provided, and substantial savings were now being made in that department. Another item of expense beyond the normal had been the cost of advertising. That was being closely watched, so as to effect considerable reductions during the current year. The extraordinary general meeting last October had sanctioned the nominal increase of the capital to £300,000. The cost of registering this capital, and the expense of issuing the prospectus and advertising, had been temporarily charged to a suspense account, and would be written off in equal instalments in about three years. Since the last meeting, 2,781 preference shares and 1,928 ordinary shares had been placed. The list of applications for debentures had also been closed, and the committee of the Stock Exchange had granted a quotation for these securities. The stock in trade showed a considerable increase over previous years. A satisfactory feature of the increase, consisting as it did mainly of finished parts of machines, was that it enabled the Company to make quick delivery, and that fact often secured them an order. The item "trade debtors" showed an apparent decrease, but that was due to the transfer of the Chelmsford lighting account to the heading of "Investments." With regard to the profit and loss account, the net profits were some £3,000 less than last year, and the Directors did not therefore recommend a full dividend on the preference shares. They felt sure that the shareholders would agree with them that that was the proper course to adopt. The dividend on the preference shares was cumulative, so that the balance of 1 per cent. unpaid was carried forward to next year as a first charge after debenture interest on the future profits of the Company. The works at Chelmsford and Lillie Bridge were in first-rate order and well equipped; the Company had a good staff of engineers and officials, and was served by an excellent body of workmen. It would be gratifying to learn that the Crompton arc lamp had been so improved that it now held the position of being the best and cheapest in the market, and considerable orders had been received for it. He then moved the adoption of the report and accounts.

Mr. R. E. Bell Crompton, in seconding the motion, said that they had not made as good a year as they ought to have done. General bad trade had had a great deal to do with it, and individual bad luck in the case of the exceptionally large sums spent on the power department for the boilers at Chelmsford had been the causes which had led to the diminished profits; but he could corroborate the Chairman that there was nothing to lead them to believe that this state of things should point towards diminished profits in future. He thought everybody would admit that the period now being passed through was a period of depression in all trades, and that it had reached a point at which they must at least hope for a turning, and he did not think they would be found unfitted to take advantage of a revival. It had been the aim of the managing Directors to look for every possible means of providing steady work for the Chelmsford shops that would be in the nature of a backbone to the business. The manufacture and sale of dynamos had always been part of such a backbone, and although Crompton and Co. for many years past had been well known as makers of arc lamps, yet for the past six or seven years it had been quite an insignificant item. They had now developed this arc lamp so as to cause it to be asked for on all sides, and that made him very hopeful that they would discover a second string to their bow in the shape of a steady manufacture which they could always go on making for stock at all times, knowing perfectly that there was certain to be a demand whenever the normal state of affairs came again. He thought during the ensuing year, from what he had seen of the demand for the new lamp, that it promised well to yield something substantial towards next year's profits. With regard to the heavy cost of the boilers he could not say very much. It was more in the nature of a pure accident that the boilers gave out as they did. They well knew that the demand in consequence of the lighting of Chelmsford being added to the ordinary demands of their works, would be very considerable during last winter, but they did not reckon upon the extreme badness of the water supply damaging the boilers before the new boilers could be got into position. The hurried work and the hired work which had to fill up between the failure of the old boilers and the getting in of the new permanent boilers was a very costly operation. He thought, however, they had taken steps to prevent the possibility of anything of the kind recurring. Of course accidents might happen, but they had taken all possible and reasonable means to prevent them. They had adopted the type of boiler that was best suited for very bad water, and in addition to that they had put down water purifying plant, and had taken advantage of the change of boilers, which would enable them to burn very cheap coal. Thus the troubles in the past might be a source of profit to them in the future. He believed the cost of producing power at Chelmsford would be very much lower than it could have been with the old type of boiler. There had already been a steady decrease in the expenses under this head. He need hardly say that the hard state of affairs affected the managing Directors more than anyone else in the Company, and they had therefore a very strong incentive to see it put right as quickly as possible. No one could regret more than himself that they had not got their full dividend. He then seconded the motion.

The **Chairman**, in reply to Colonel Wood as to the depreciation fund, said he believed that their plant was put down in the depre-

ciation account to its full amount, and that it had this year been increased by £500. The amount was sufficient to cover all ordinary expenses and wear and tear, but he did not know that it could cover every accident In answer to Mr. Kitchin, he remarked that the Chelmsford lighting was getting in a satisfactory state, and in a short time they hoped it would be paying its way on fairly commercial lines With regard to the cost of the breaking down of the boilers, they had had to expend a considerable amount (£2,000) on temporary work alone to enable them to carry on the lighting. As to the increase of stock, that cut both ways. They had been trying some time to meet orders when wanted in a hurry, and very often an order could be secured and carried out with a given stock, whereas with a low stock they lost the business. Whether they had reached the happy medium of having too much or too little he could not say, but they had stock that would enable them to deal with orders which otherwise they might lose. With regard to investments in shares of other companies, their object was not to do anything of that kind, but they were sometimes obliged to have an interest in some companies in order to get orders.

The resolution was then put to the meeting, and was unanimously adopted.

On the motion of the **Chairman**, seconded by **Mr. J F Albright**, a dividend of 2s 6d. per share, making with the interim dividend 6 per cent. per annum on the preference shares, was declared.

Mr. H. H J. W. Drummond was re-elected a director, and Messrs. J. H. Duncan and Co were reappointed auditors. A vote of thanks to the Board terminated the proceedings.

DIRECT UNITED STATES CABLE COMPANY.

The thirty-second ordinary general meeting of the Direct United States Cable Company, Limited was held on the 29th ult. at Winchester House, under the presidency of Sir John Pender

The **Chairman**, in moving the adoption of the report, said the revenue for the half year ended June 30 last, after deducting out-payments, amounted to £40,836, and the working and other expenses to £18,898, leaving a balance of £21,938 as the net profit of the half year. This with £3,129 brought forward from the previous half year, made a total of £25,067. Three quarterly interim dividends of 3s. 6d each per share amounting to £31,872. 15s. had been declared and paid during the financial year, and a final payment of 3s 6d. per share was now proposed, making, with the three interim dividends, 3½ per cent for the year, being a total distribution of £42,497 After transferring £3,000 to the reserve fund account, which now stood at £267,415. 12s. 7d, the balance of £819. 2s 4d. on the revenue account was proposed to be carried forward. The revenue, as compared with that of the corresponding period of the previous year, showed an increase of £1,822. Considering the general depression which had prevailed, this result must be regarded as satisfactory.

The report and accounts were adopted.

ANGLO-AMERICAN TELEGRAPH COMPANY.

The half yearly general meeting of the Anglo American Telegraph Company, Limited, took place on the 29th ult., at Winchester House.

The **Marquis of Tweeddale**, in moving the adoption of the report, said that the receipts had amounted to £146,886, an increase of £367, and the best the Company had experienced for some time The beginning of this month was unsatisfactory, but the latter part of it had placed the receipts a little above what they were last year. The working expenses showed an increase of £818, mainly due to the loss caused by fire at St. Johns, and to the increase in salaries. The net result had been an interim dividend of 12s. 6d on the ordinary stock not a very large return, but it was paid on a stock which had been heavily watered to the extent of about 50 per cent. The proprietors had no doubt noticed with a certain amount of satisfaction that the reserve fund now stood at £1,007,261, or £7,000 above the million of which they had often talked. Whether this sum could be made available for dividend purposes must depend on the freedom from further interruption, and on the speed and economy with which the present interruptions were being repaired.

The report was adopted.

ELECTRICAL POWER STORAGE COMPANY.

The fourth ordinary meeting of this Company was held at the offices of the Company, 4, Great Winchester-street, E C., on July 27, Mr. J. Irving Courtenay, the chairman of the Company, presiding.

We have been favoured with the following report of this meeting by the secretary of the Company

The Secretary (Mr. J W Barnard) having read the notice convening the meeting, the **Chairman** said In making some observations upon the accounts, I desire to point out that the difference in the balance carried forward from the trading account this year and last year is mainly owing to proper deductions having been made in balancing the trading account, the discounts and other charges having been deducted before bringing forward the balance. The gross amount of orders is larger than last year, but owing to the reduction in price, and increased discounts to the trade, the net cash received is rather less. But you will also notice that in consequence of economies having been introduced into the management and into the manufacture, the net profits are practically the same, because from the amount of the profits we have written off this year £1,500 towards depreciation of patents. The Company is selling more of its manufactures than it did, and thus it is increasing its goodwill and obtaining a larger business with the public, because the objections taken in past years to the high price of accumulators have been to a considerable extent a removed by the reductions in question Now you are all aware of the depressed condition of trade, and that the electrical industry, like all other businesses, is suffering from the depressed times, but I am glad to say that the E P S Company has done well in spite of this almost unprecedented depression We do business with all the leading firms, and the result is that whatever business is going we get a share of. We have competition to contend against, and no doubt shall always have, but I think by the improvements that have actually been made, and those we have in contemplation, and by the economies these will effect in the manufacture of the batteries, we shall be able to hold our own. We are, as you are aware, also acquiring patents for details in manufacture, and so in reality, though the basic patents are growing older, we are strengthening the position by these newer patents. One of the most vital questions for the E. P. S. Company is traction. You know that this Company associates itself almost entirely with what is called self-contained traction, and has endeavoured to develop it, though up to the present not with the results we aim at; but we do not for one moment despair of ultimate success A portion of the expenditure in legal charges was incurred in what at one time looked a hopeful business in endeavouring to obtain an Act of Parliament in an important provincial town for an electrical tramway We failed because we could not get the necessary agreements confirmed in time for Parliament, and so the Bill was dropped. But we are persevering (not in that particular locality) with self contained traction, and you have heard of a small company that has been formed -I refer to the Pioneer Electric Carriage Company to develop a form of traction with novel features, among which is the pneumatic wheel Some few of our friends have put their money in to test it, and, if successful, it will be a great benefit to the E P S Company and bring a wide demand for its batteries—such is the interest the E.P S has in the welfare of that concern. I do not think I need trouble you with any further remarks, and conclude by saying so far as is possible to see ahead in these days, I entertain no doubt that the E P S. Company will continue to prosper. I now move: "That the Directors' report and statement of accounts to May 31, 1893, be and are hereby approved and adopted, and that a dividend of 5 per cent on the paid up capital be declared, payable on August 24, 1893."

Sir Daniel Cooper. I beg to second.

Mr. J W Barclay: I do not intend to offer any criticism of the accounts, but to refer to a point which invites attention—viz., the use of accumulators for propelling carriages. Shareholders of the Pioneer Electric Carriage Company are endeavouring, at their own expense, to develop a system of self contained traction for ordinary carriages. If the attempt prove successful, a very wide field for the use of accumulators will be opened up. Meanwhile the problem we have before us is to prove that this new method of locomotion is useful, commodious, and economical. The operations of the Pioneer Company should certainly encourage shareholders to be hopeful for the future of the electric storage battery industry.

The resolution was then carried unanimously, and the retiring director, Sir Daniel Cooper, Bart., G C M G, having been re-elected, other formal business was concluded. In responding to a vote of thanks, the **Chairman** observed: I should like to say I have waited for this opportunity of expressing our indebtedness to Mr. Frank King and staff for the keen and intelligent energy with which they have pushed the business of this Company. The Directors will bear me out when I say that Mr King and his staff spare no effort to promote in all directions the interests of the E.P S Company.

Mr. Frank King On behalf of the staff and myself, I beg to thank the meeting and the chairman. It is our duty to convince engineers and others that the secondary battery, as manufactured by the Company, is the very best battery, for all purposes, they could possibly desire. We have been successful in this, and it is a great satisfaction to us to know that our efforts are appreciated.

The proceedings then terminated.

The following is the report of the Directors and accounts of the Company for the year ended May 31, 1893:

The profit, after payment of general expenses, management, etc., is £5,245 2s. 2d, from which the Directors have, in deference to the wishes of the auditors, deducted a sum of £1,500, writing that amount off the patent account, leaving with a balance of £626 7s 7d. from last year, an amount of £4,371. 9s. 9d available for distribution, out of which the Directors recommend the payment of a dividend of 5 per cent., leaving £158 19s. 5d. to be carried forward. Provision has also been made for maintenance of buildings, plant, tools, etc., by writing off the sum of £2,083 18s. 9d. The Directors are pleased to be able to report the continued success of the Company's operations; a considerable reduction in the selling price of its manufactures has been made, for the purpose of bringing storage batteries into more general use Particular attention has been devoted to securing such inventions as would tend to cheapen production while combining maximum efficiency and durability, and with this object several new patents have been acquired, and sole licenses for others have been obtained. Constant attention has been also given to the development of electric traction, for which the Directors expect a considerable demand will shortly arise. The Company and its licensees have been successful in patent litigation abroad. The retiring Director is Sir Daniel Cooper, Bart., G.C.M.G., who, being eligible, offers

himself for re-election. The auditors, Messrs. Broads, Paterson, and Co., retire as usual.

BALANCE-SHEET, MAY 31, 1893.

GLOBE TELEGRAPH AND TRUST COMPANY.

The twentieth ordinary general meeting was held on the 27th ult. at Winchester House, under the presidency of Sir John Pender, M.P.

The **Chairman**, in moving the adoption of the report, said the net revenue for the year ended July 18, after the payment of expenses, amounted to £188,931, as against £192,243 last year, or a decrease of £3,312. This decrease, which was but a small one considering the general depression which had existed during the past year, was accounted for by the fact that they had received somewhat reduced dividends from four or five of the companies in which they held investments. On the other hand, there were two or three of the companies which had given them a better return this year than they did in the previous year. This enabled the Directors to recommend the payment of a dividend on the ordinary shares of 4½ per cent. for the year under review. Last year they were able to pay 4¾ per cent., or 6d. more than they proposed to pay this year. The average dividend which the Company had paid since its formation in 1873 was 4¾ per cent., so that the present dividend was above the average, and therefore it was not disappointing.

The **Marquis of Tweeddale** seconded the resolution, which was carried.

CHILI TELEPHONE COMPANY, LIMITED.

The ordinary general meeting was held on Wednesday at Winchester House, Colonel R. Raynsford Jackson (chairman) presiding.

In moving the adoption of the report, which was given in our last issue, the **Chairman** said that the net profits in London for the past year amounted to only £5,395, although the income in dollars from subscribers showed an increase of 69,834dol. The fact was that the fall in exchange was directly responsible for a diminution in their revenue of £7,642. As the tariff rates were paid in the paper dollar, which was now so greatly depreciated, the Board felt that they ought to increase these rates. Already that course had been pursued in some important centres, and they were about to do the same in all of them. Another thing on which they relied was the decision arrived at by the Chilian Government to gradually withdraw the paper money and establish a sound currency. The profit earned during the past year was used for capital purposes, but they had now practically closed that account, at least for the present, as they were only spending the money necessary to couple up new subscribers. He hoped, therefore, that during the current year they might be able to set aside, out of revenue, a sufficient amount with which to pay a dividend.

Mr. T. Greenwood seconded the motion, and the report was adopted.

MANCHESTER EDISON-SWAN COMPANY, LIMITED.

The eleventh ordinary general meeting of this Company was held last week, Mr. V. K. Armitage, chairman of the Company, presiding.

In the annual report which was taken as read, it was stated that the net profit, including last year's balance, amounted to £2,047 14s. 9d. Of this it was proposed to devote £1,000 to the payment of a dividend at the rate of 5 per cent. per annum, and £873 15s. towards the loss incurred in connection with the Williamson Electrical and Engineering Company, Limited, of Australia, carrying forward a balance of £173 19s. 9d.

The **Chairman**, in moving the adoption of the report, referred to the depressed state of electrical business and business in general during the past year, and said the Manchester Edison Swan Company had suffered a good deal through the delay of the Manchester Corporation in carrying out their installation, as people did not care to go forward with installations on their own account till they saw what the Corporation were going to do in the matter. The Corporation seemed now to be within measurable distance of the completion of their works. The net profits of the Company had been about £800 less than in the preceding year. Although the result was to that extent unfavourable, he was not without hope as to the future of the Company. There could be no doubt that there would be a very great spread of electric lighting in the immediate future, and they hoped and believed they would get their share of the work that had to be done. Nearly all the business they had done had been remunerative work, and with increased business they would have an increase in the amount of their profits.

The motion was seconded by **Mr. W. P. James Fawcus**, and after some criticisms on the accounts had been passed, it was put to the meeting and adopted with only one dissentient.

It was agreed that the profits should be disposed of in the manner suggested in the report, except that out of the balance to be carried forward £150 was voted as remuneration to the Directors.

BUSINESS NOTES.

Cuba Submarine Telegraph Company.—The Directors propose a half yearly dividend at the rate of 8 per cent. per annum.

South London Railway.—The City and South London Railway Bill was read on Monday in the House of Lords for the third time.

Burnley.—It was mentioned on Wednesday at a meeting of the Town Council, that the electric light station had now been completed, and that the current would be switched on next week.

Lyons.—The central telephone offices at Lyons took fire on Saturday, and it was found necessary to cut the whole of the 1,250 connecting wires. The damage sustained is estimated at £1,000.

Mill Lighting.—A new spinning mill, recently erected at Eagley for Messrs. J. Chadwick and Brother, Limited, is being lighted electrically by Messrs. Ernest Scott and Mountain, Limited, of Newcastle.

Agents Wanted.—As will be seen from our advertisement columns, Mr. Ronald A. Scott, of Acton Hill, London, W., is desirous of appointing a good agent for Newcastle, Liverpool, and Cardiff, and the adjoining districts.

Bolton.—An inquiry was to be held yesterday by Major-General Crozier, R.E., one of her Majesty's Local Government Inspectors, into an application by the Bolton Corporation for sanction to borrow £40,000 for the purposes of electric lighting.

Hampstead - Charing Cross Railway.—On Monday the Unopposed Bill Committee of the House of Lords passed the Hampstead, St. Pancras, and Charing Cross Electric Railway Bill. This scheme has been sanctioned by the House of Commons.

Electrocution.—A defect in the chair on the carrying out of the execution of Wm. Taylor at Auburn Prison, New York, caused the dynamo to give out, and a second shock could not be given for an hour. The current in the latter case was obtained from the street mains.

City and South London Railway Company.—The receipts for the week ending July 30 were £822, against £735 for the same period last year, or an increase of £87. The total receipts for the second half year of 1893 show an increase of £404 over those for the corresponding period of 1892.

Nottingham.—The Electric Lighting Committee of the Corporation have opened the tenders (11 in number) for the electric light station to be erected in Lower Talbot street. The tender of Mr. F. Messom, of Nottingham, builder and contractor, was accepted, at the price of £10,209.

Lancaster.—Tenders for the erection of engine and boiler house, etc., at the central station for electric lighting in Lancaster, have been let to the following tradesmen of the town: Mason's work, Mr. W. Harrison; joiner's work, Mr. Jonathan Acton; plumbing, Mr. William Abbott; plastering, Messrs. T. Cross and Son.

Exhibition at Nottingham.—An industrial exhibition, organised in honour of the forthcoming visit of the British Association, was opened in the Victoria Hall on Wednesday. The electric light of the building has been carried out by Messrs. Defries and Sons, and the Electric Wire and Fittings Company show a variety of electric lamps.

Incandescent Lamps.—We are informed that Mr. F. Espir, of 3, East India avenue, Leadenhall street, E.C., has been appointed sole agent in this country for the Société Anonyme pour la Construction de Lampes à Incandescence of Budapest (the Budapest Incandescence Lamp Company) in view of the anticipated trade in imported lamps.

Agricultural Show at Dewsbury.—At one of the stands the Wray Electrical Engineering Company, of Bradford, show fittings necessary for the installation of electric light in a country house or a flour mill. The dynamo is worked by an oil engine. An Otto gas engine, by Messrs. Crossley Bros., Limited, is shown driving a Crompton dynamo.

Australian and Canadian Cable.—The laying of the Queensland and New Caledonia telegraph cable, which will form the first section of the projected cable between Australia and Canada, will shortly be commenced, and is expected to be finished by the end of August. The laying of the continuation to Vancouver will probably be completed within two years.

Coventry.—At a meeting on Tuesday of the City Council, under the presidency of the mayor, the Electric Light Committee recommended that they be empowered to employ a consulting engineer, but the mayor moved that before this was done the committee present a full report of their investigations up to the present time, and after some discussion this motion was adopted.

Coventry.—At a meeting of the Warwickshire County Council, the Roads and Bridges Committee mentioned that terms had been arranged with Mr. Graff Baker for the introduction of electric trams at Coventry, and as Mr. Graff Baker had now sold his interest in the tramways company, they recommended that the seal be affixed to an agreement with the new company.

Telephony between Belfast and Glasgow.—The postal authorities have arranged that parties desirous of communicating with Belfast by telephone may do so by applying at the public counter at the post office. The charge is 3s. for a conversation of not more than three minutes' duration, but the uninterrupted use of the wire may be secured for six minutes on payment of a double fee.

Electricity in Coal Mining.—The use of electricity in Welsh coal mines is on the increase. Blaennant, in the Aberdare Valley, is now electrically lighted, and at Abercanaid the Plymouth Collieries are illuminated extensively. Messrs. Crawshay have adopted the electric light for their colliery at Pontypridd, and it is stated that in the next winter Cyfarthfa Works will be similarly illuminated.

The Eastern Empire.—A new hall, built on the site of what was once Marlow's, is being opened this week in the East End of the metropolis. The hall is lighted by electricity from plant laid down in a roomy engine house at the back of the stage. Messrs. Vaughan and Brown, of 16 and 17, Kirby street, E.C., have carried out the installation in a very creditable manner, Mr. G. C. Vaughan, jun., having superintended the work.

Hampstead.—The tender of Messrs. R. A. Yerbury and Sons, of Kilburn, for the erection of a chimney shaft and buildings for the Hampstead central station, with foundations for the machinery, etc., in conformity with specifications and plans prepared by Mr. Preece, has been accepted for £7,350, and the tender of Messrs. Siemens Bros. and Co., for the supply of electric lighting plant, mains, etc., for the area at first to be lighted, has been accepted for £19,794.

Incandescent Electric Lamp Company, Limited.—This company has been registered by J. Fraser and Sons, 31, Copthall avenue, E.C., with a capital of £25,000 in £10 shares. The object is to carry on the manufacture and sale of electric lamps, fittings, appliances, and materials. There shall not be less than three nor more than seven directors. The first are J. Fraser, G. Binswanger, and C. J. Robertson. The qualification is £500.

Rugby.—On Saturday the Local Board received an application from the Rugby School Electric Lighting Company asking the Board to undertake the task of laying the cast-iron pipes for the cables where they crossed the public road, in order to avoid the difficulty of having to make good and maintain the surface of the road afterwards. The Board agreed to undertake the work, subject to their being relieved from all subsequent responsibility.

Lighting of Newspaper Offices.—The electric light installation in the offices of the *Yorkshire Post* is now complete, and consists of upwards of 400 incandescent lamps and four arc lamps. There are 200 lights in the composing department. The current is obtained from the Yorkshire House to House Electricity Company, and the scheme of the installation, with the specifications, was prepared and superintended by Mr. E. W. Lancaster, of Birmingham. The contract was undertaken by Messrs. S. Dixon and Son, of Leeds.

Bandon.—A public meeting was held on Monday to consider whether the Town Commissioners should oppose or consent to the application of the Bandon Electric Lighting Company for a provisional order. Mr. C. Crowley presided over the gathering. Mr. George Beare was opposed to the application, and he would propose that the ratepayers should instruct counsel to oppose the application made to the Town Commissioners. Mr. Sullivan seconded the resolution, which, after some discussion, was carried.

Blackpool and Lytham Tramways.—The Blackpool, St. Anne's, and Lytham Tramways Bill has been finally passed by Lord Morley's Committee of the House of Lords. The National Telephone Company and the railway companies asked for an amendment of the "model clause" inserted in the Bill on the recommendation of the Joint Committee, to the effect that the Board of Trade should have power to extend the time for the reconstruction of the system of wires. The committee decided to amend the clause, so as to give the Board of Trade power to extend the time.

Edinburgh.—At a meeting on Monday of the Edinburgh and Leith Gas Commission, a letter was read from the town clerk asking if the Commissioners would be willing to supply the Corporation of Edinburgh with gas for their engines, to be used in the production of electric light, at the same rate as they do at present for public lighting. The rate at which the gas would be supplied, it was pointed out in the letter, would be an important matter in coming to a decision whether they would use gas engines or not. After some discussion the matter was remitted to the Works Committee.

Lighting at Osborne.—In connection with the festivities at Cowes this week, her Majesty the Queen on Monday entertained a party of guests in the Indian-room, which in its splendid whiteness never looked so well as when illuminated by the many electric lights distributed in vases, bronze bowls, and in the exquisite "exhibition" set of Minton china and biscuit work, in which the turquoise blue contrasts so well with the delicate figures representing the four seasons and the pleasures of sport. The success of the electric lighting was due to Mr. Massey, the Queen's electrician.

A Reported Amalgamation.—It has been stated in several well informed quarters that an early amalgamation will be effected between the firms and businesses of Messrs. Goolden and Co. and Messrs. Easton and Anderson, Limited, though we do not know exactly with how much truth the statement is made, or what details, if any, have been settled. Probably the Woodfield Works are to be kept for the light manufactures, and heavier goods made at Erith. In view of the progress which ought to be achieved by electric traction in the early future, such an amalgamation—if it be a fact—should promise great success.

Derby.—On Wednesday, at a meeting of the Town Council, it was mentioned that Messrs. G. Fletcher and Co. had delivered three boilers under a contract in connection with the electric lighting works. The Highway Committee had approved of the proposed positions of the transformer boxes. The work of laying the cables has been commenced, and arrangements have been made with Messrs. Siemens for them to undertake the reinstatement of the pavement for the work they are at present doing, for £500. The Mayor requested the Council to adopt the minutes, which was seconded by Alderman Sowter, and carried.

Pontypool.—The surveyor reported at the monthly meeting of the Local Board last week, that the Pontypool Electric Light and Power Company, Limited, had completed laying their mains, but that they were rather dilatory in replacing the paving of the George street footpath. It was agreed that the surveyor call upon the company to replace the whole of the paving in accordance with their undertaking. The chairman read a letter from the Board of Trade, stating that they had received a certificate that the Pontypool Electric Light Company had expended the amount of money authorised by their license, and that they would release their deposit of £1,000.

Worthy of Consideration.—In one of our notes some time since reference was made to gas making apparatus. A correspondent from Sydney has written us on the subject, and from his letter we gather that there is room for the Dowson or some other system of the kind among consumers in Australia. Our correspondent, Mr. H. G. Masterman, of Victoria arcade, Sydney, consumes about 3,000 cubic feet of gas per day, for working a lift and getting the electric light: gas is 5s. per 1,000. We have forwarded another letter to the agent for the American system referred to in our note, but the opening is not blocked to Englishmen. Mr. Masterman says "there is a good opening for the invention here; if we put in the appliance there are plenty more would follow."

The Government and the Telephones.—In the House on Monday, Mr. Harry Foster asked the Postmaster General whether an agreement was now being settled between the Post Office and the National Telephone Company for the purchase by the Post Office of the National Company's trunk wires, or for the settlement of other matters. Mr Arnold Morley said the agreement with the National Telephone Company of 1892, with the Treasury minute of that year, was in the course of settlement, and in pursuance of the recommendations of the Select Committee would be laid before Parliament, but the committee were of opinion that the responsibility for the details rested with the Government, and he did not propose to lay it on the table before it was signed. The agreement would be on the lines of the minute.

Halifax.—When the members of the Halifax Flour Society met last Friday, the Secretary (Mr. Kendall) gave some important information as to the saving the society had effected by adopting the electric light. For 1892 their total payments for gas and the electric lighting amounted to £122. In 1890, when they had no electric light, their gas account was £174. There was thus a difference of about £52. That, however, was not all, as by putting in the electric light they effected a saving on their insurance of between £60 and £70 per annum. Mr Kendall added that the figures were all the more significant when they took into consideration that two years ago they ground 100,048 quarters, and last year 127,156 quarters. The use of gas, he said, was now almost confined to their stables.

Dundee.—In the course of his presidential address before the North British Association of Gas Managers, at the annual meeting in Dundee, Mr. T. Douglas Hall said that not only did Dundee possess fully and efficiently equipped gasworks, but there was a completely equipped electric light station, which had cost the Gas Commissioners, under whose control it was, about £30,000, and he was of opinion that the conclusion of the association, after they had visited both, would be that in respect of electric lighting Dundee was second to no other city. Without, however, condemning or attempting to justify the actions of public bodies, he said that electricity had not yet proved itself to be anything more than a luxury, while gas had become a necessity; and it was to be hoped that the Dundee Gas Commissioners in their wisdom would make the electric light department stand on its own legs, as in the case of gas, and that those who used electricity should alone be required to pay for it.

Grimsby.—The subject of electric lighting was discussed at a meeting last week of the Highways Committee of the Town Council. The borough surveyor intimated that he had written, in accordance with the request of the committee, to 47 places where the electric light was largely in use, with a view to getting information as to the advisability of illuminating the streets by electricity. He had received 16 replies, all within the last day or two, and was expecting more very shortly. The surveyor briefly went through the chief statements embodied in the letters received, one of which stated that the cost of electric lighting had been found to be three times as much as lighting by gas, and that the illuminating power gained was 10 times as great. On the motion of Mr. Jeffs, seconded by Mr Barrett, it was decided to adjourn the consideration of the subject for the present, the surveyor before the next meeting to supply each member, in printed form, with the chief items of the information then to hand.

Oriental Telephone Company.—The House of Lords has given judgment in the appeal in the case of Addison and others v. Ness. The question depended on the construction of an agreement made between the promoters of the Oriental Telephone Company, Limited, and the company itself, which was incorporated in 1881, with a nominal capital of £300,000 in £1 shares. The promoters were to receive a certain number of vendors' shares, fully paid up, as part satisfaction of the purchase money payable to them, the rest of the shares being ordinary. It was part of the agreement that during the first five years of the company's existence the holders of the vendors' shares should not participate in the profits of the company until the holders of the ordinary shares should have been paid a dividend of 6 per cent per annum. Mr. Justice Kekewich decided in favour of the appellants, who represented the ordinary shareholders, but his decision was reversed on appeal. Hence the present appeal. The judgment of the Court of Appeal was now reversed, and the respondent ordered to pay the costs.

Lighting of Hamburg.—We understand that a contract for the extension of the Hamburg electric light station and the distribution of electric energy over the whole area of the town has been given to Messrs. Schuckert and Co., Limited, of Nuremberg. It may be interesting to mention some particulars, as electricity will be used to a large extent as motive power. About 300 h.p. will be used for some tram lines in the town, and if this proves satisfactory, as is expected, all the tramways in the town, requiring about 1,000 h.p., will be operated by electricity. It is intended to connect the central railway station, which is to be erected, and which will require a large amount of current for light and power, with the generating station. In addition, 500 h.p. has to be provided for the working of cranes in the harbours. This is, however, not in connection with the free harbours, for which a large electric station was built in 1888 by Messrs. Schuckert and Co. A railway like the Berlin railway is projected for Hamburg, but to be constructed as a circular line, and it is proposed to use electricity as the driving power.

Southport Lighting.—On Wednesday a special meeting of the Town Council took place to consider the reports made by Mr. Wilkinson, electrical engineer, respecting the proposal for the electric lighting of a portion of the town. In his reports the engineer submitted two statements of capital expenditure required to carry out the scheme. The low-tension system he estimated to cost £13,255, which would mean the exclusion of Bold street, Promenade (from Bold street to Nevill street), and London street (from Chapel-street to Wright street) from the supply mains. The cost for the high tension alternating system, with station at Crowlands, was £13,297. The Gas and Electric Lighting Committee recommended the Council to adopt a proposal to supply the town area with electrical energy from generating plant erected at Crowlands. After a lengthy discussion, Councillor Dimond moved an amendment to the effect that the town area be supplied with electrical energy on the alternating current system from generating plant erected at Crowlands, and that tenders be invited for the building and plant. This amendment was put and unanimously carried.

Acton Hill Electrical Works.—The fifth annual sports in connection with the Acton Hill Electrical Engineering Works took place on Saturday in the grounds of The Elms, Acton Hill, by permission of Captain Ronald A. Scott. The weather was fine and the attendance was large. A committee, at the head of which was Captain R. A. Scott, superintended the sports; the other members were Messrs. Toy, Square, Turrell, Onslow, and Moore; hon. sec., Mr. Garrett; timekeeper, Mr. Hodgson. The course was on grass, seven laps to the mile, and the following are some of the results: 100 yards handicap—final heat: Fyson, first; C. J. Broomfield, second; Moore, third. High jump—H. Square, 5ft. 1in., first; J. H. McLaren, 5ft., second. Quarter mile handicap—H. N. Fyson (35 yards start), first; C. J. Bromfield (10), second. Long jump—H. Square, 17ft., first; E. H. Turrell, 16ft. 4in., second. Hurdle race (100 yards)—final heat: R. Needham, first; R. S. Walker (owes three yards), second; C. W. Barber, third; C. J. Bromfield (owes three yards), 0. Putting the weight—C. J. Bromfield, 31ft. 2in., first; E. H. Turrell, 30ft. 8in., second. Mile handicap—S. Chavasse (100 yards start), first; A. Smith (100), second; H. Hunt (120), third. The prizes were distributed by Mrs. Ronald Scott, and this brought to a close an enjoyable afternoon.

Glasgow.—The committee of the Town Council on electric lighting have had under consideration a proposal for the extension of the system. The scheme submitted contemplates the removal of the dynamos from the establishment in Waterloo-street to the premises in John street formerly occupied by Messrs. Mavor, Coulson, and Co., and now belonging to the Corporation, with the view of utilising them for supplying electricity for street-lighting purposes. This would leave room at Waterloo street for the installation of plant for the supply of incandescent light for house lighting, and for carrying out the necessary alterations it was agreed to recommend an expenditure of £5,000. The Corporation are at present supplying electricity for house lighting within the compulsory area, but mains have been laid down outside this area, and at the rate applications are coming in it would speedily become impossible to meet the demand. Provision will also have to be made for the lighting of Argyll street as soon as the railway operations permit, and for this additional power will be required. In the John street premises there are two powerful engines, with the necessary connections, which can at once be utilised, and which may meanwhile render unnecessary the acquisition of additional plant of this description. Some other questions have emerged for consideration, and the whole subject was remitted to a sub-committee.

Peterborough.—The question of lighting Peterborough by electricity was considered by the Town Council at the monthly meeting last week. The Lighting Committee stated that the engineer had reported upon the application of the Midland House-to-House Electricity Company for the consent of the Corporation for them to apply for a provisional order giving them power to supply electricity within the borough, whereupon Mr. Herbert proposed in committee the following resolution: "It being the intention of the Corporation themselves to eventually provide electric lighting for the city, we inform the Midland House-to-House Electricity Company of this intention, and object to their obtaining powers for this purpose." Mr. Hunting proposed that the engineer give a further report upon the points mentioned by him in his report, which was seconded by Mr. Manton, and carried. Mr. Miller moved the non-confirmation of the minute on the ground that it might lead the Council to assume a position which they were not likely to carry out. Alderman Redhead, who seconded, did not consider it was at all necessary for any report to be made upon the question. The Mayor said the question of electric lighting was being pressed forward in the town, and there was a very strong feeling amongst a considerable number of tradesmen that the time had come for electric lighting to be adopted, and they, as a Council, certainly could not stand in the way of such a feeling. The Mayor put Mr. Miller's amendment, which was defeated by 11 votes to four.

Shrewsbury.—The Town Council have held a special meeting to consider a communication from the Shropshire Electric Light and Power Company regarding the introduction of the light in the borough. The Mayor (Mr. G. Evans) presided. Mr. W. C. C. Peele attended as a deputation from the company. Alderman Southam said, as he moved the resolution in March, he would now propose the following: "That the resolution of the Council passed on the 9th day of March, 1891, in reference to an application made by the Shropshire Electric Light and Power Company, Limited, be and is hereby rescinded." This was seconded by Mr. W. M. How. After some discussion, the Council decided that the actual report of the borough surveyor on the information obtained by him should be read. The following are quotations: "It will be noticed that only two out of the 73 cities or towns in Great Britain—viz., Brighton and Glasgow, use water as the motive power for generating the light; in the others steam is used. "The

charge of the light to the several consumers varies from 9d. to 4½d. per unit. The former price is equal to gas supplied at 6s. per 1,000 cubic feet, and the latter at 3s. per 1,000 cubic feet. The average may be taken at 7d. per unit, or equal to gas supplied at 4s. 8d. per 1,000 cubic feet. The cost of fitting up of premises for the light will be much cheaper next year owing to the patent rights for the incandescent lamp dropping out. The lamps can then be purchased from 9d. to 1s., instead of 3s 6d. each, the present price. The damage and injury caused by gas to ceilings, pictures, and goods of every description should also be taken into account, and which reduces the cost of the electric light as against gas as an illuminant. A Special Electric Lighting Committee, appointed by the Vestry of the parish of St. Mary, Islington, in their report have gone very fully into the whole subject, and state in their opinion from the knowledge and information gained since its appointment that the supply of the electric light can no longer be regarded as a speculative business, but on the contrary, must be admitted to be an undertaking of great benefit to the public, and of assured commercial success. In conclusion, I strongly recommend your committee to seek an expert's opinion on a subject of so much importance to the borough and, from the statements before you, one that should if carried into effect, be remunerative as well as a comfort. Should your committee call in an opinion, I shall be pleased to give every assistance within my power." Further discussion then ensued, and on the motion being put, it was carried by 14 votes to five. Alderman Southam then moved the following resolution: "That the consent of the Council be and is hereby granted to the application of the Shropshire Electric Light and Power Company, Limited, for a provisional order to be confirmed by Parliament, power being reserved for the Council to purchase the undertaking at the end of 21, 28, or 35 years from the date of commencement of such provisional order, at a price to be agreed upon or fixed by arbitration." In doing so, he said as a very old Salopian, and as one who was anxious that the old town of Shrewsbury should keep pace with other towns of a like size, it was exceedingly desirable that they should not let the opportunity go by of having the electric light in the borough. Mr W. L. Browne, in seconding the resolution, thought they should offer every encouragement to the company to prosecute their undertaking, and he hoped they would soon see the streets of Shrewsbury lit by electricity. The resolution was eventually adopted.

PROVISIONAL PATENTS, 1893.

JULY 24.

14233. **An improved method of transmitting electrical calls or signals.** Thomas Joseph Gough, 33, Moseley street, Manchester.

14258. **An improved electricity meter for registering the amount of current consumed on direct or alternating circuits.** Frederick John Beaumont and Frederick Hallows, 37, Stockwell Park crescent, Brixton, London.

14259. **Improvements in dynamo-electric machines.** William Lawrie, 117, Bishopsgate street Within, London.

14271. **Improvements in the method of distributing electricity through sub-stations, and in apparatus for that purpose.** Charles Bertram and William John Hope-Johnstone, 70, Chancery lane, London.

JULY 25.

14298. **Improvements in the production of filaments for incandescent electric lamps.** Harry Kneebone Tomkins, 52, Whiteley-road, Gipsy hill, Surrey.

14315. **Improvements in galvanic elements.** Carl Wilhelm Adolf Hertel, 57, Barton arcade, Manchester. (Complete specification.)

JULY 26.

14422. **Improvements in apparatus for covering electric cables or conductors.** James Bassnett Atherton, 6, Lord street, Liverpool.

JULY 27.

14469. **Improvements in electric arc lamps.** Amos William Richardson, 6, Bank street, Manchester.

14474. **Improvements in the arrangement of telephone circuits and in apparatus therefor.** Sir Charles Stewart Forbes, Bart., 21, Finsbury pavement, London. (Complete specification.)

14481. **Improvements in ammeters and voltmeters.** Ernest Francis Moy and Francis Teague, 433, Strand, London.

14485. **Improvements in multiple point switches suitable for use in electric lighting.** Francis Henry Nalder, Herbert Nalder, Charles William Scott Crawley, and Alfred Soames, 24, Southampton buildings, Chancery lane, London. (Complete specification.)

14486. **Improvements in electrically working armoured turrets, guns, and other apparatus, and in apparatus suitable for these purposes.** Sydney Pitt, 24, Southampton buildings, Chancery-lane, London. (Messrs. Sautter, Harlé, and Cie., France.) Complete specification.)

14489. **Improvements in or connected with turnstiles and electric counters connected therewith.** Ramon Chavarria Contardo, Norfolk House, Norfolk street, *London. (Complete specification.)*

14492. **Improvements in or in connection with electric conductors.** George Gatton Melhuish Hardingham, 191, Fleet street, London. (The firm of Felten and Guilleaume, Germany.)

14498. **Improvements in dynamo-electric generators and motors.** John Brokenshire Furneaux and George William Money, 46, Lincoln's-inn fields, London.

JULY 28.

14505. **A process and apparatus for obtaining pure metallic manganese by electrolysis.** Ludwig Voltmer, 11, Southampton buildings, Chancery lane, London.

14516. **Improvements in and connected with electric furnaces.** August Friedrich Wilhelm Kreinsen, 70, Market street, Manchester. (Complete specification.)

14525. **An improvement in relation to the covers for casings carrying electric light conductors.** Harry Christie Harold, 30, St. Swithin's lane, London.

14533. **Improvements in supplying electrical energy to motor vehicles on electric railways, and to electromotors on vessels by means of alternative current transformers.** Siemens Bros. and Co., Limited, 28, Southampton buildings, Chancery lane, London. (Messrs. Siemens and Halske, Germany.)

14534. **A cathode for electrolysis.** Henrik Christian Fredrik Störmer, 28, Southampton buildings, Chancery lane, London.

14556. **Improvements in apparatus for raising and lowering bodies, applicable, for instance, to electric and other lamps, and railway carriage and other blinds, and to hoisting gear.** Reuben Thomas Preston and Arthur Bernard Gill, 77, Chancery lane, London.

14562. **Improvements in alternate current dynamos and synchronising motors.** Henry Willock Ravenshaw and Llewellyn Birchall Atkinson, 1, Queen Victoria street, London.

JULY 29.

14628. **Improvements in or connected with cells or batteries for use in electrolysis.** Ferdinand Hurter, 47, Lincoln's-inn fields, London.

16335A. **Improvements in induction coils.** Edward Marshall Harrison, Monument chambers, King William street, London. (Date claimed under Patents Rule 19, Sept. 13, 1892.) (Complete specification.)

16335B. **Improvements in magneto electric generators.** Edward Marshall Harrison, Monument chambers, King William-street, London. (Date claimed under Patents Rule 19, Sept. 13, 1892.) (Complete specification.)

16335C. **Improvements in electric bells.** Edward Marshall Harrison, Monument chambers, King William street, London. (Date claimed under Patents Rule 19, Sept. 13, 1892.) (Complete specification.)

SPECIFICATIONS PUBLISHED

1892.

13297. **Electropathic appliances.** Horn. (Mears and another.)

13702. **Telephonic system for transmitting news.** Puskas.

14181. **Electric batteries.** Shrewsbury and Dobell.

16124. **Telephonic switching apparatus.** Bennett.

1893.

7387. **Electrically welding metals.** Thompson. (Coffin.)

9304. **Electric incandescent lamps.** Boult. (Waring.)

NOTES.

Ventilation.—The prevailing hot weather should do good to the suppliers of electric ventilating fans.

Welding Rails.—The rails of the West End Company, Cambridge, Mass., are being welded by electricity from a portable plant.

Gatling Gun.—An electric cartridge-feeder has been applied to the Gatling gun. This allows of an increase in the firing capacity.

Electrocution.—A burnt-out armature was the cause of the failure in the supply of current at the execution referred to last week.

Berlin-Koenigsberg Telephone.—The long-distance telephone between Berlin and Koenigsberg has been ready for some weeks, but is not yet in public use.

Sanitary Works.—The sanitary works at Rochdale are lighted by electricity, and, according to Councillor Hardman, they are the only works of the kind electrically illuminated.

South London Railway.—We are glad to learn that experiments are being made with a view to improve the illumination of the carriages on this railway. This is a step in the right direction.

Calais.—The port of Calais has long had electric light both on the lighthouse and at the landing-stage and hotel. The town of Calais is now to have electric light, as a central station is being built for M. Dehaynin.

Gaulard.—*L'Elettricità* gives an article by Prof. A. Volta on Luciano Gaulard, the pioneer introducer of the present transformer. A striking portrait of the unfortunate inventor accompanies this appreciative notice.

Storage Battery Patents.—A brighter outlook for the storage battery in America is thought likely after the judgment of Judge Coxe, recently pronounced, declaring void the Faure pasted-plate patent in the United States.

Liverpool Electric Railway.—This railway, during the 16 weeks covered by the accounts just issued to the shareholders, carried 1,370,742 passengers, or at the rate of 4,300,000 per annum. The service of the trains is very regular.

Mayence.—The General Electricity Company of Berlin and Messrs. Schuckert and Co., of Nuremberg, having approached the Mayence Town Council with a view to introducing the electric light, the latter is appointing a commission to consider the subject.

Nuremberg.—The Nuremberg Tramway Company intend to have their line run electrically. Instead of going to their own firm—Schuckert—they seem to have arranged with the Berlin Allgemeine Company for the equipment. It will be on the overhead trolley system.

Exhibition at Antwerp.—As mentioned in a previous issue, an international exhibition is to be opened at Antwerp next May. It is under the patronage of the King of the Belgians, and will comprise industrial, scientific, and artistic productions, as well as commercial produce.

Electric Power.—There is a growing tendency on the Continent to introduce electric power in engineering shops and in coal mines. At the Gutehoffnungshutte, at Sterkrade, all the machinery and tools in the bridge-building shop are operated electrically, and other works are about to follow this example.

New Caledonia Cable.—The cable for the submarine telegraph between Queensland and New Caledonia has been completed by the Société Générale des Telephones, of Calais. The steamer "François Arago," now at Calais, is being loaded, and will at once proceed to lay the cable.

Telephony.—Proposals are being made, not only in Glasgow, but also in Manchester, for a municipal telephone service. This is a step in the right direction, but it must not be forgotten that subscribers to local exchanges, in order to get inter-town communication, must also subscribe to the latter system.

Aluminium.—The French Electro-Metallurgical Company are about to start their aluminium works. Possessed of 30,000 h.p. in water power, they have sufficient for many extensions. They have only established conduits for 3,000 h.p., and will use but 1,000 h.p. at present, though machinery to utilise another 1,000 h.p. will shortly be put down.

Portable Installations.—A description is given in *La Lumière Electrique* last week of several types of portable electric light installations, by Messrs. Fein and the Schuckert Company. The waggons are very compactly arranged in fire-engine style, and a good feature is introduced in the tripod masts for arc lamps, which seem very convenient to handle.

Long-Distance Transmission.—An installation of electrical transmission of energy a distance of 28 miles at 10,000 volts, is to be found in the case of the San Antonio Light and Power Company at Pomona, California. Water power is used. The efficiency of the water-power plant is 83·5 per cent., of the electric system 63 per cent., and the total efficiency of the entire system is 52·2 per cent.

Electric Works.—*L'Electricien*, in its business supplement, has quite a list of electric works to be let and second-hand machinery to be sold in France. Amongst these offers is "a large central station of 3,000 lamps installed, with plant necessary to light 6,000 lamps; monopoly for 40 years. Orders for 4,000 more lamps in hand." This seems an enticing offer for a company wishing to invest capital.

Cologne.—Complaints having been raised by the customers of the Cologne municipal electric station as to the high cost of the lamps, the authorities have issued a pamphlet calling attention to the fact that many consumers use 25 c.p. lamps instead of the usual standard of 16 c.p. The municipality propose to sell lamps giving a guaranteed 16 c.p., and consuming 52 to 56 watts, at 8d. each. The demand for electric light under these favourable conditions will probably increase quickly.

Life of Incandescent Lamps.—From a tabular statement given in *L'Electricien*, it appears that the practical utility of lamps consuming little current per normal candle is very limited, and that as a general rule lamps which take from 3 to 3½ watts per candle are to be recommended. The conclusions to be drawn from the table are as follows: Lamps consuming 1½ watts per nominal candle last 45 lighting hours; those taking two watts, 200 hours; lamps consuming 2½ watts, 450 hours; and those taking three watts and 3½ watts, both 1,000 hours.

Electrolysis of Pipes.—The destruction of underground pipes by electrolysis by the action of currents from the electric railway has been noticed at several places in Hamilton, Canada. The *Canadian Architect* suggests the following protection as worthy of consideration and trial: "Wrap the pipe with a covering of tarred (pine tar) hemp about ½in. thick before burying it; give the outside of the pipe a thick coat, or two or three coats, of a good hard, but elastic japan which has been well dried in an oven; let the outside of the pipe be enamelled with an elastic enamel;

Electricity in Quarrying.—Experiments have been made in this direction during the past two or three years by Mr Edison. He quarries a low grade of iron ore, and lifts and transports it by means of two cable lines to the crushers. After being crushed, the material is gradually pulverised; then by an electric process the particles are separated from the particles of stone, and are compressed into bricks and sold as a high percentage iron ore. These operations necessitate the use of hoisting engines, drills, pumps, etc. The electric drill is being discarded, and the steam drill substituted.

"Faraday House Journal."—An electrical students' paper has appeared under the title of the *Faraday House Journal*, price 6d. monthly. It contains much writing, rather weak for the most part, on the training of electrical engineers, and has articles abounding in such expressions as "rot" and "dry up." This will distinctly appeal to student nature, while the immense advantages to parents of training their boys as "Faradians" and the value of "affiliation" are insisted upon and reiterated at full length. Sixpence seems a high price to pay for such material, but no doubt it is meant to be given away.

Electric Tramways.—It has yet to be shown what action the traction companies intend to take in view of the recent recommendations of the Joint Parliamentary Committee on electric traction powers. The clauses recommended by the latter have already been introduced in several Bills, and may now be accepted as model clauses, although in two or three cases the time has been slightly extended. The tramway companies are bound hand and foot so far as fresh capital expenditure is concerned, and it lies with the electric traction people and local authorities to set the ball rolling in this direction. Who will be the first?

Central Stations.—The *Elektrotechnische Zeitschrift* of the 4th inst. contains a long descriptive and illustrated acount of the central stations at Cassel and at Chur (Switzerland). At Cassel both alternate and direct current are used, the latter with Hagen accumulators. Oerlikon supplies the dynamos, and Siemens cables are laid. At Chur, as is now well known, alternate-current motors are commonly at work; the smaller motors are connected to the lighting mains, and the larger ones have special mains to supply them. Oerlikon machines are again used, and Girard turbines supply the motive power from the waterfall about 1½ miles from the town.

Cooking by Electricity.—An attempt is being made in Manchester to popularise the use of electricity for cooking purposes, and experiments in this direction have just been conducted at the offices of the Manchester Edison and Swan Electric Light Company. On the 4th inst. a dinner of five courses was cooked by electricity, the *menu* consisting of julienne soup, boiled salmon and shrimp sauce, veal cutlets and tomato sauce, leg of lamb, with French beans and potatoes, greengage tart and Victoria cream. The cooking was pronounced a complete success. In the kitchen the interesting operation of cooking by the new process was witnessed by a few privileged guests.

Storage Battery Traction in Paris.—In the course of a letter to a correspondent, sent in correction of some statements made by a Montreal paper, M Julien, of Brussels, states that horse traction in Paris costs 52 centimes for each vehicle per kilometre, while traction by electricity only amounts to 45 centimes. The horse cars, moreover, have only 48 seats, while the electric cars seat 56 persons, which makes, on the one hand, a decrease of seven centimes on the traction, and an increase in the receipts which may be put down on an average at 1f. 60c. per trip. Continuing, M. Julien says that as the car covers 115 kilometres and eight trips daily, the benefit is therefore 20f. per day for each car.

Waterloo and City Railway.—The directors of the London and South-Western Railway attach great importance to the Waterloo and City Railway, the Bill of which has passed through both Houses. Mr. Wyndham S. Portal, chairman of the former railway company, mentioned on Wednesday that the line would give the South-Western Railway easy access to the City, and that there would be a station near to the Bank and the Mansion House. The company which was to construct the proposed railway was independent, but the Act contained powers authorising the South-Western Company to work the line when it was finished. At their next meeting the terms of an agreement between the two companies would probably have to be discussed.

Prizes.—The Société Industrielle of Mulhouse offers for 1894 several medals and other prizes for papers or solutions of industrial problems. A medal will be given for an electric motor capable of developing variable speeds and powers at will ranging at least from one to ten, and presenting no variation of efficiency greater than 20 per cent. The power must be at least 10 h.p., and the efficiency equal to that of the motors now ordinarily in use. A medal will also be given for a paper dealing with the comparative cost of lighting a town of 30,000 inhabitants with gas and electric light. There are several other prizes, as, for instance, for any application of electricity to printing, for an instrument for determining the amount of water dragged by steam out of the boiler; for a registering totaliser of work done by an engine. Papers must be sent by February 25, 1894, to La Société Industrielle, Mulhouse.

Variation of Copper Deposition.—According to the law enounced by Faraday, the quantity of metal deposited on an anode by a given current should remain the same whatever the composition of the electrodes. This, however, is not so according to Herr Oettel, who states in the *Chemiker Zeitung* that with platinum electrodes the deposit of copper is only from 74 to 89 per cent. of that obtained with copper electrodes, the current being the same (0·13 ampere per decimetre square), and no hydrogen being given off. The cause of this divergence is the formation at the anode of persulphuric acid and hydrogen, which become diffused in the liquid, and on reaching the cathode are reduced, thus causing a reduction in the amount of metal deposited. The addition of some easily oxidisable substance, such as formic acid, annuls the action of these secondary products and increases the quantity of copper deposited to 98 up to 99·6 per cent. of the theoretical value. Alcohol is still more efficacious, and brings the deposit up to 99·9 per cent. of the theoretical amount.

Goebel Lamps.—The decision in the Goebel lamp case has been given, and is against Goebel's advocates, though their case stands better than before. At the last suit the judge thought it impossible to believe that a lamp should have been constructed by Goebel previous to 1877. This time Judge Leaman gives it as his opinion: "Against all of the improbabilities of this claim, the story as related by Goebel in his several affidavits, with detail confirmations by many witnesses, is interesting, circumstantial, and in many respects plausible." However, the burden of proof lay with Goebel, and the judge goes on to show where doubts existed, and decided that the complainant was entitled to an injunction. This is a victory for the General Electric Company. But it is felt that the want of liberal treatment has estranged so many companies that the rich royalties they might have

reaped are now past praying for. Many firms have brought out non-infringing lamps, and the lamp war is likely to wage as furiously as ever.

Smoke Consumers.—Inventions for prevention or consumption of smoke in boilers are almost innumerable, but the one recently brought before our notice by Messrs. Edwards and Wright has advantages which seem to promise good results. The practical trials bear out this promise, and boilers have already been fitted at Sheffield and elsewhere with very satisfactory effects. Certainly Sheffield could do with many smoke consumers, and London is not without desires in this direction. The apparatus is simple, consisting of a hollow iron bridge connected with a pipe, into which air is forced by a steam jet or a fan. The bridge itself is hot, and the pipe passing through the furnace is likewise heated, so that the air issues at a high temperature. On starting the boiler, thick smoke only issues for half a minute or so, and afterwards there is little or none to be seen. There is very little alteration to be done in fixing. The apparatus can be explained at the offices, 19, Laurence Pountney-lane, and seen at various boiler houses where it has been fixed.

Manufacture of Accumulators.—We do not trouble much about the disagreeablenesses of manufactures over here. A grumble about vibration or a too objectionable smell is the extent of our protestations. London is too smoky, too dirty, and too busy to worry about small beauties. In Paris it is different. With clean streets, fine buildings everywhere, and clear air, every factory is well looked after to prevent nuisance. The Paris Council of Hygiene has invited the Prefect of Police to give his opinion on the manufacture of accumulators. Working with oxides of lead and sulphuric acid, and giving off explosive fumes, should they come under "class 3"—lead foundries with special regulations? M. Michel Levy pointed out, with justice, that accumulator manufacture was a new trade and ought not to be too much fettered. Therefore, for the present every such factory is under the special rules, which allows each factory to be separately considered. The Council of Hygiene has wisely determined to gather a sufficient number of the results of experience before issuing any decided rules.

Prevention of Sparking.—The Déri-Blathy method of preventing sparking in alternate-current motors (or, as the writer conveniently terms them, alternomotors), is given in an article by M. F. Guilbert, in *La Lumière Electrique* for the 29th ult. The principle is simple, and consists in introducing a resistance, or, still better, a self-induction, in the conductors which connect the segments of the commutator to the sections of the armature. The armature may be of any form desired—drum, ring, or disc—and is wound as for a continuous-current machine, with the difference that the point of junction of the two consecutive sections is not connected direct to the commutator segment, but through a special circuit which has an appropriate resistance or self-induction, generally both of suitably-chosen amounts. These circuits diminish the current in the short-circuited coils. The resistance is chosen as low as possible while having high self induction. The coils may be wound on the armature itself or on a second laminated ring. Diagrams are given for ring and drum armature. The application seems to be intended for the continuous type of motor modified for driving by alternate currents.

High-Frequency Experiments.—We have already mentioned M. d'Arsonval's experiments with high-frequency currents. A description, with some diagrams of apparatus, is given by Dr. P. Oudin in *L'Electricien*, August 5. The sparks from a Ruhmkorff coil are allowed to pass between knobs—the stems being connected to the inside of Leyden jars. The two outside coatings are connected together by a high-resistance circuit, and from the ends of this circuit, near the coatings, wires are connected to two other knobs. It is the oscillatory current between these latter which are used. Sometimes the current is again passed into other coils of varying form. Enormous pressures are obtained, and ozone can be produced of a more intense odour than with any other apparatus. Dr. Oudin, at the end of his paper, mentions an experiment with a thermometer. Holding it by the reservoir, the upper end is placed in the spiral of wire thus energised. The upper part of the tube becomes irradiated in the thickness of the glass by a mass of small sparks of startling brilliancy. These at first short, penetrate deeper into the glass, and when one attains the outer face of the tube it at once goes out. The tube is then found to be very warm, and the body of it is rendered almost opaque by minute cracks in its substance.

The Thunderstorm.—A thunderstorm of great brilliancy, but apparently little damage, burst over London about one o'clock yesterday morning. The flashes of lightning were for more than an hour almost continuous, and sheets of lambent fire played about the heavens in unwonted splendour. It was extremely interesting to watch the varied nature of the flashes as they appeared to the eye. At first gentle bursts of silent flame illumined for a moment small patches of cloud. Then a broader sheet seemed to spread across the whole sky, against which the houses and trees became vividly outlined. Then, again, at other flashes the whole district seemed to be enveloped in a vivid violet smoke for the instant of the flash, the whole face of the landscape taking a violet tinge. As the storm came nearer, the hitherto silent discharges were accompanied by the sharp crash and long roll of the thunder, and the overflow discharge seemed plainly to be seen at some of the stronger flashes in a way that would please Dr. Lodge's heart. A blinding flash would quiver down the sky in a jagged curve; at once a secondary discharge took place at a certain distance away, and again a fainter flash, showing but a slight glow away on the horizon. This threefold discharge was often noticed, and was very suggestive. The storm followed a most oppressive day, and was certainly one of the most vivid recently seen.

Electric Interlocking.—M. Hubou read a practical paper on electric interlocking on railway lines before the Société des Ingénieurs Civils on the 21st ult. Electricity is especially useful, says the author, to interlock levers working separately or placed at long distances apart. By means of a Chaperon controller placed at the points, the signal which protects it may be locked. Electric bolts are also used. All the signal points along the route of the trains being furnished with electric bolts placed in series in the same circuit, the signals cannot be put to "line clear" except when all these bolts are locked in their normal place; and, conversely, the bolts cannot be unlocked until the signals corresponding, themselves fitted with electric bolts, are locked at "danger." Besides this these electric bolts can be controlled from a station by means of switches allowing the current to be sent or cut off, so as to allow or stop shunting operations. In the circuits pedals can also be inserted to complete the interlocking, so that if a train wrongly clears an open distant signal, the corresponding pass signal cannot be given. Electricity, adds M. Hubou, is usually employed in the form of continuous currents. But induction currents might also be used, and the mechanical transmission could be entirely

done away with by using electric discs. M. Hubou showed at his lecture actual models of the interlocking bolts and switch used on the lines of the Lyons Company.

Pacific Cable.—The even flow of the negotiations with regard to the establishment of a British cable across the Pacific to North America has been disturbed, says the *Daily Chronicle's* representative at Victoria, by the advent of the French company with its plans for a cable from Queensland to New Caledonia. Mr. Patterson, the Victorian Premier, has addressed a protest to the Governments of Queensland and New South Wales in that they have committed themselves to make a cable to New Caledonia, the first section of the Pacific cable, and thus assist in hindering the project for a British cable line to Vancouver by any other route. Mr. Patterson protested against being compelled to accept the New Caledonian route without consultation, and said he should be glad to learn that Queensland and New South Wales were still free to contract for a main Pacific cable otherwise than *via* New Caledonia. No reply has been received to these representations, but Mr. Patterson has written to the Imperial and Canadian Governments disclaiming responsibility for the selection of the New Caledonian route, and both the New Zealand and Tasmanian Governments have expressed agreement with the position he has assumed.

Telephone Statistics.—Some interesting particulars have been published in a French journal concerning the progress in telephonic communication during the past eight or nine years in Europe. At the close of 1883, Belgium and Switzerland had more telephones than any other country. Switzerland now has nearly 10,000 miles of telephone wires, with over 10,000 subscribers, who exchange about 8,000,000 communications in the course of the year. Belgium, in 1883, had telephones in six towns, and 2,300 subscribers, whereas now there are about 12,000 miles of wires with about 6,000 subscribers, who exchange upwards of 10,000,000 messages. In Italy the telephone was limited to six or seven principal cities, which, with a total population of two and a half million inhabitants, had 7,269 subscribers. Germany, in 1883, had 5,838 subscribers in the 33 principal towns, and has now about 70,000 miles of wires, with 49,531 subscribers exchanging about 257,000,000 communications. Denmark had only telephonic communication in Copenhagen, where there were 863 subscribers; and in Russia, where the telephone was confined to six or seven of the largest towns, there were only 2,000 subscribers. The principal towns of Holland had 1,718 subscribers, while in France there were 6,113 subscribers in towns the total population of which was rather over four millions. The progress in France since the State took over the telephones has been very rapid, and there are now about 20,000 subscribers for the 112 towns which possess telephonic communication, this being exclusive of the telephones from town to town.

Chimney Stacks for Central Stations. — The almost universal custom in this country as regards large chimney or smoke stack construction is to employ stone or brick as the material of which these structures are composed. It is perhaps typical of English solidity that tall chimneys should be built as though they were intended to endure for generations. American practice, however, has for some time now tended in the direction of using iron or steel for this purpose, and the reasons to be assigned for it are not unimportant. First of all they are constructed at a less cost and in much quicker time—doubtless the latter reason appealing specially to the desire to rush matters, which is rather too frequent in the United States. Then, again, the metallic chimney stacks are said to be much stronger in proportion, whilst they can be readily taken down if it is required. One would think, however, that the great variations in temperature would affect an iron or steel chimney to a much greater extent than brick or stone, whilst the æsthetic appearance of a cylindrical pipe is anything but charming, even when compared with the English "rounded pyramids." Moreover, it is hardly possible to attain a suitable height, and therefore draught, with a metallic chimney, so that a fan giving forced draught becomes necessary. In view, however, of the extensions which will take place in our central stations (as the demand for current increases), it may be worth while going into the question of chimney construction unbiassed by the conservatism of previous custom. The greatest objection would appear to be the cooling of the heated gases, so that a metal chimney might not give such a good draught.

Commercial Translations.—The London Chamber of Commerce has recently livened its methods by the starting on new journalistic ventures, determined to cater for an extended usefulness. There is another department of useful work to which we might draw attention, important alike to traders at home and abroad, which may perhaps commend itself to the committee. This is the preparation and translation of foreign circulars. It is a significant fact that the Imperial Austrian Commercial Museum (K. K. Handels-Museum, 11, Borsegasse, Vienna) have recently organised a department for this purpose, and will undertake to prepare and translate any circular in any ordinary language free of charge. This generous advocacy and aid to commercial enterprise cannot be without its effect, for many firms only hesitate to extend their market from want of knowledge of the languages. It may conceivably be worth the while of the London Chamber to do the same for our merchants. But without going so far as this, it might be pointed out that the Chamber's list of persons seeking positions always contain a number of men "thoroughly conversant with" French, German, Spanish, Swedish, Dutch, Portuguese, etc., as the case may be. While they are seeking other employment it is evident they would be willing enough to occupy themselves with translation of circulars or other work of this kind, under the Chamber, for moderate fees. If organised under competent supervision, and the work looked through by a native (such as for Spanish electrical technics, Senor Tolra, who already does this work at Adam-street, Adelphi), these unengaged persons might help themselves, the Chamber, and the merchants in a similar way to that done by the Austrian Handels-Museum, even if it were not possible to do the work entirely free of charge.

Potential of the Atmosphere.—What is the difference of potential between the air at the top of the Eiffel Tower and of the ground at the foot? This is the question, interesting alike to electricians and to meteorologists, which has been put to and the answer sought by M. Chauveau, of the Meteorological Department at Paris. The result is rather astonishing. One would expect a few volts difference of potential—even a few hundred volts. But the answer is 10,000 volts! This certainly seems extraordinary at the height of 1,000ft. only, yet on a recent visit to the Eiffel Tower one of our representatives saw the attendant at his tests, and the amount was then over 7,000 volts. A noticeable spark, clearly seen and heard in broad daylight, of some millimetres length, was taken from the outside knob. This apparatus is of the simplest, but accurate means of measurement are installed. A Thomson battery of several hundred volts as standard, a reflecting potentiometer, and a photographic register of the light spot are the means used for obtaining the curves of rise and fall of potential. Plotted against curves of thermometer, barometer, and hygrometer, this will probably tell an

interesting tale. The means of obtaining the potential of the surrounding air adopted is that, suggested by Lord Kelvin, of discharging fine streams of water. A small tube attached to a cistern of water projects out into the air for some 6ft. or 8ft. The tube and cistern are very carefully insulated, and a wire is led down to a knob within reaching distance, also highly insulated. On turning on the water-jet a fine stream of water floats away on the air; in a minute or two the whole apparatus, which has some considerable capacity, is charged and sparks can be obtained. In registering, a wire is carefully taken through into the dark room and registers automatically in the way mentioned. M. Chauveau devotes a good deal of time and attention to this interesting experiment, mounting the Eiffel Tower every day, rain or shine, and on some days in winter when the wind blows a perfect gale this is by no means a pleasant or even a safe task. In winter, of course, the reading is very difficult, for the water freezes, and the other way to obtain the potential, by means of a gas flame, is not less troublesome. Sufficient curves have been taken, however, to lead to interesting results. The potential rises and falls in well-defined curves, and very nearly a year's records have been obtained. The potential varies very much—from 3,000 to 7,000 volts is common—and on a brilliant, clear day at this time of the year 10,000 volts, we were told, was not uncommon.

The Hydrophone.—In a previous issue reference was made to this apparatus, which has been devised by Captain M'Evoy. Its object is to inform port authorities or a fleet of the approach of a torpedo-boat, even if the latter is entirely submerged. The following details of the apparatus will prove interesting: It consists essentially of two parts, one submerged in the sea at a suitable distance from the port or fleet to be warned, and at a depth sufficient to escape the surface agitation. This part may be described as an iron bell jar, which, on being plunged mouth downwards into the water, retains a volume of air in the upper portion or bottom, where a copper box, protecting the sensitive organ of the apparatus, is fixed. The organ in question is merely a very delicate vibratory contact, which makes and breaks an electric circuit connecting the submerged bell with the indicator or second part of the hydrophone, situated on shore or on board one of the ships of the fleet. The contact is formed by a flat horizontal spring, fixed at one end, and loaded at the other by a heavy piece of brass, having on its upper surface a small platinum stud. A fine platinum needle kept upright by a vertical guide rests its lower end loosely on the platinum stud. The needle and the stud are connected in the electric circuit through the guide and spring, and when the needle dances on the stud the circuit is made and broken. An electric current from the ship or shore battery is always flowing through the circuit—that is to say, between the submerged bell and the indicator. Now the propeller of a torpedo-boat or of a torpedo sets up vibrations in the water, and these, reaching the submerged bell, agitate the trembling contact, so that the needle dances on the stud and interrupts the current. The consequence is that the indicator begins to work and announces the submarine disturbance. This part of the hydrophone consists essentially of an electromagnet through which the current passes, with an armature free to oscillate when the circuit is rapidly made and broken—that is to say, when the current becomes intermittent. The motions of this armature can be seen by an observer if he chooses to watch, but actual observation is not required, for the indicator itself gives the alarm. This takes place when the swing of the armature carries it within the attraction of a magnetic contact-piece fixed near it. The armature is then drawn to the contact-piece and held fast there. The swing armature and the contact-piece are connected in the circuit of a local battery, and when they meet the current flows to ring an electric bell or light an electric lamp. The torpedo-boat thus announces its own arrival on the scene in spite of itself, and precautions can be taken against it. The hydrophone is at present undergoing a practical trial in the Solent, and the inventor estimates that three of the instruments suitably placed would be sufficient to protect Portsmouth Harbour. He is now engaged in constructing a larger bell than that already submerged, in order to meet the requirements of the Government authorities.

Action of Electricity on Microbes.—Attention has been called to the process of electrification for living bodies adopted by M. d'Arsonval, which consists in raising a current of very high frequency (800,000 per second) in a solenoid, into which the beings or the parts of their bodies to be experimented on are placed. By reason of the enormous induction developed in such a system, the bodies placed within the solenoid become the seat of currents circulating within their tissues and around each molecule at the frequency mentioned. The larger animals bear these currents without appreciable discomfort, and a man can easily bear energy to bring several lamps to incandescence. MM. d'Arsonval and Charrin have now attempted to find out how a microbe would stand the charge. One of the best known has been chosen—the pyocyanique bacillus—whose habits have been already well studied by MM. Gessard and Charrin. We do not know as yet much about the effect of electricity upon microbes. Important as the subject may be, it involves contradictions, as in ordinary applications it is often the heat or the gases liberated in a nascent state that act upon the germs. In these experiments, however, it may be taken that electricity pure is acting. A culture of the pyocyanogen bacteria is placed in the solenoid excited as above mentioned. Before the experiment two drops of this culture are placed in a tube, then the same is done after 10, 20, 60 minutes in a second, third, and fourth tube, and these four tubes are put to mature. A simple examination of these tubes shows that in all of them the bacillus germinates abundantly; the increase is about equal; its form does not undergo any great change, nor do its pathogenic functions. But the power of secreting pigments is modified: while the first two tubes show an intense blue-green tint, hardly at all lessened in the second, the last two show the greenish tint much less accentuated. There is no doubt the chromogenic power of the bacillus has been affected. Thus it is demonstrated that we have another agent, electricity—for heat, light, and movement have already been studied—which may act upon the bacterial world—in short, upon living cells; and it is thus understood how the electric state of the atmosphere may exert an influence upon the germ diseases, upon epidemics which are known to depend to some extent upon cosmic conditions. MM. d'Arsonval and Charrin also point out that this electricity also affects the vitality of our own bodies, and consequently the gravity or otherwise of certain diseases. We well know, even in the present state of our knowledge, of the influence of thunderstorms on certain ferments—on the lactic ferment, for instance; for every dairymaid knows that "thunder turns the milk sour" This discovery of MM. d'Arsonval and Charrin of the influence of electricity on the chromogenic function of bacilli may therefore be the first of a series which will eventually enable us to generalise upon the mutual interdependence of climatic conditions, and the spread and, it is to be hoped, the prevention of disease.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

(Continued from page 79.)

INCANDESCENT LIGHTING.

The light given off by the second kind of electric lamp—namely, the incandescent or glow lamp—is really due to the same cause as that which produces the arc light—*i.e.*, carbon raised to an incandescent or glowing state by means of electric energy. In the arc lamp the crater is white hot carbon, and in the incandescent lamp the whole of the filament is made white hot. The reason why the light of an incandescent lamp is so much below that of an arc lamp is because the carbon filament of the former is only raised to about the temperature of melting platinum, say 1,800deg. C. or 2,000deg. C., whilst the crater of the arc is raised much above this, perhaps up to 6,000deg. C.; certainly not below 3,000deg. C.

The incandescent lamp, as is generally known by this time, consists of a very thin thread of carbonised fibre, technically called the "filament," hermetically sealed within a pear-shaped glass bulb, which is exhausted of air as much as possible. The filament is bent parallel, somewhat after the manner of a hairpin, and sometimes has a curl at the bend. The two ends of the filament are jointed on to two platinum wires, which pass, embedded, through the neck of the bulb and make contact with two brass terminals. These terminals are fixed in plaster of Paris, thus forming a terminal collar to the lamp. Unlike the arc lamp, the incandescent lamp is seen to its best advantage for indoor illumination, and being of small candle-power the light can be distributed in any way desirable, and fixed in any place.

Illuminating Powers.—For the same amount of electrical energy spent an arc lamp will give from eight to nine times the amount of light that an incandescent lamp will give. An arc lamp gives, say, 1,000 c.p. for 400 watts; this is at the rate of 2·5 candles per watt, or ·4 of a watt per candle-power. An incandescent lamp of 16 c.p. absorbs, say, 56 watts, and this is at the rate of ·28 candle per watt, or 3·5 watts per candle-power. These lamps are made with a great variety of candle power, and also to burn at various pressures. The standard size is a lamp of 16 c.p. to run at 100 volts pressure, because this is the most common pressure adopted in consumers' houses. The same sized lamp can, however, be made to run at a higher or lower voltage, such as 50 volts or 120 volts. For indoor illumination, 8 c.p. and 32 c.p. are also greatly used, the smaller one being very useful for lighting places that do not require much light—such as corridors, stair cases, small rooms, recesses, etc.; the larger light is useful for places where an extra illumination is required—as shop windows, billiard tables, etc. The very large sizes—as 100, 200, and 500—are known as "Sunbeams, and are mostly used for lighting large rooms, entrance halls, or outdoor. These lamps are not used very much because their "life" is not long, and they blacken and decrease rapidly in candle-power. In addition to all the above, there are very small lamps of five, three, two, and half candle-power—3 c.p. is generally found in miners' electric hand lamps, where the lamp is connected up to an accumulator battery. The smallest lamps are used in theatrical effects, and in surgical and such like operations.

A lamp of same candle-power and efficiency consumes the same energy whatever voltage it may be made for, because the lower the pressure the greater must its current be. For example, a 16 c.p. lamp at 100 volts pressure has a filament of about 180 ohms resistance, and will therefore take a current of $100 \div 180 = \cdot 55$ of an ampere. Suppose a similar lamp is required to run on a circuit which is at a pressure of 50 volts, evidently at this pressure only half the current would flow through the filament: therefore to have the same current the resistance of the filament must be halved, and this means doubling the sectional area. But although we have now the same current, we only use half the pressure, consequently only one-half the electrical energy, or number of watts, because $50 \times \cdot 55$ is one-half of $100 \times \cdot 55$. To get the same quantity of light we must utilise the same amount of energy. By again halving the resistance, or again doubling the sectional area of the filament, we get 1·1 amperes through, and then $50 \times 1 \cdot 1$ equals $100 \times \cdot 55$; so that to run a lamp at half the voltage requires double the current, and the filament will have four times the sectional area, or double the diameter. Generally, then, as the working voltage decreases, the diameter of the filament increases. It is very easy to distinguish between an 8 c.p. and a 16 c.p. lamp when the candle-power number is illegible: the 8-c.p. lamp has a much finer filament than the 16 c.p. when both are made for the same voltage. The tabulation below gives the current that various sized lamps take.

TABULATION 23.

Candle-power.	Volts.	Amperes.	Watts.
1	2 8	1·5	4·2
2	25	·32	8
5	50	·4	20
8	100	·32	32
16	100	·56	56
32	100	1·12	112
50	100	1·75	175
100	100	3·5	350
200	100	7·0	700
500	100	17·5	1,750

Of course there are a number of other pressures that lamps are made for besides 100 volts, but that is the most common one for incandescent lamps. Where storage batteries are employed in conjunction with machinery at private establishments, the circuit pressure is often fixed for 50, 60, or 70 volts. Then there are lamps made for 105 and 110 volts.

A lamp should only be run at the voltage for what it is made. If this be not done, then when the voltage is lower the light will fall off enormously, and when the voltage is higher the light will be enormously increased, but the lamp will be quickly burnt out. To show how rapidly and out of proportion the light of a lamp varies when its voltage, and hence its current, is varied, the figures given below are the result of an experiment made on a 50-volt lamp of 16 c.p. taking 52 watts.

TABULATION 24.

Volts.	Candle-power.	Watts.
25	·4	14·0
29 5	·87	19·
34 8	2·47	26·9
40·0	5 1	35·9
48·0	12·6	46 3
49·0	15·0	50 5
50·0	15·8	52·7
52 5	20·5	57·5
52 6	28·4	64 5
59 5	39·3	72·9
62·0	50·7	79 9
68·2	74·5	96·7
72·5	103·2	107·5

By studying the above figures it is seen that when the voltage has fallen two volts, or 4 per cent., the light has fallen no less than 21 per cent., or more than one-fifth. Approximately, the variation of candle-power is in proportion to the sixth power of the voltages—this is limited to within about 20 per cent. below and 20 per cent. above the normal candle-power. Numerous empiric rules have been formulated for expressing the rise and fall of candle-power in terms of the voltage, but none of them are of much service for practical purposes, and the rough rule given above will be found sufficient for most purposes. Upon applying it to the example just quoted, it will be found that it holds true and is almost exactly correct, for the ratio between the sixth powers of 48 and 50 is about 4 : 5, and four-fifths of 15·8 works out 12·6; similarly the ratio of the sixth powers of 50 and 52·5 is about 3 : 4, and 15·8 multiplied by 4 and divided by 3 gives 21, which is near enough to 20·5 given by the table.

An incandescent lamp of 16 c.p. will illuminate well a floor area of about 50 square feet when placed, say, 10ft.

high, and will give a good ordinary light for every 80 square feet. A large percentage of the light goes upward when the lamp is fixed with its holder uppermost, and when the lamp is fixed on a table standard, or on brackets, so that the bulb is upwards, more light goes upwards than downwards. So it is essential to use reflecting shades if it is required to direct the light in any way and obtain its full benefit, such as for reading purposes, workshop benches, and all places where each individual wants a small light to himself. It is in this case that the advantage and superiority of the incandescent is mostly proved over every other kind of light—even the arc lamp is then at a disadvantage. The lamp suspended by a flexible cable can be raised and lowered, as desired ; it can be placed within an inch or so of any work to be examined, and when provided with a hand support and length of flexible cable can be placed and carried about anywhere. For reading, perhaps the pleasantest kind of shade is green porcelain having a white enamelled interior surface. Rooms and halls having whitewashed ceilings require less illuminating power than those which have not. Similarly, rooms with light coloured wall paper reflect more light than those with dark coloured paper.

The illuminating power of all incandescent lamps deteriorates with duration of burning, and the longer they burn, the more their light is diminished. When the lamps have reached a certain stage of dimness, it is uneconomical to keep them burning, and they should then be replaced by new lamps, the old ones being either broken or placed in some unimportant place where a decreased light is of little moment. A great deal of the deterioration of the light is certainly due to the blackening of the inside of the glass bulb, caused by the gradual disintegration of the carbon filament, which action deposits a fine film of carbon on the surface of the glass. There are one or two other causes, such as the thinning of the filament as it disintegrates. This increases its resistance, and so helps to diminish the light ; beyond this there is not much knowledge on the matter : it is suggested that the vacuum becomes less perfect. To retain the initial illuminating power of a lamp is the most important problem to solve in their manufacture, and to effect this the filament must be made durable, and able to withstand high temperatures. The glass bulb is made either clear or clouded : in the former case the filament is exposed to the eye, and is painful to look upon, owing to its intensity ; by having the glass clouded or frosted the filament is hidden, and the light is diffused over the bulb, hence giving a subdued and more pleasing effect. Any loss of light that may result from this kind is amply compensated by the increased comfort their use confers.

Life and Efficiency.—The average life of a 16-c.p. lamp is estimated to be close upon 1,000 hours. A few break in a few hours, but this is very seldom, and they are defective lamps ; others have various lives, ranging from hundreds to over 1,000 hours, whilst others, again, have been known to last over 3,000 hours, but the majority of lamps work out to an average somewhere about 1,000 hours ; hence this number may be taken when making calculations respecting their running costs. The following figures show how the candle power falls off in different stages of their life, being the result of tests made at Cornell University on a 16 c.p. lamp worked at 100 volts pressure ; the decrease of energy consumed is also given :

Tabulation 25.

—	At start.	100 hrs.	200 hrs.	400 hrs.	800 hrs.
Candle-power	16	12·5	10·8	9·67	7·2
Watts	48·24	46·21	45·9	43·61	42·33
Watts per c.p. ..	3·01	3·69	4·25	4·51	5·88

The efficiency of an incandescent lamp is often interpreted as the rate of initial electric power it consumes in comparison with the initial light given out ; thus, a lamp which takes only 40 watts, and gives 16 c.p., when new is termed a high-efficiency lamp, whereas a lamp that takes 64 watts, and gives 16 c.p., is termed a low efficiency lamp. Normal efficiency being generally granted when a lamp takes 54 watts, or 3·5 watts per candle-power. The term efficiency when employed in this way is very misleading, because, although a so called high efficiency lamp only consumes small power at the commencement of its life, it unfortunately has a short life, and the candle-power diminishes very rapidly; and the smaller that this initial power is, the shorter becomes the life of the lamp, and the more does its light diminish. On the other hand, by using a so-called low-efficiency lamp, the large consumption of initial power is accompanied by a long life, and only a small decrease of candle-power.

There are, then, three chief factors that enter into the real efficiency of the lamp, and these are : (1) life of the lamp ; (2) mean candle-power ; (3) mean power used. These factors depend on the way in which the lamps are manufactured, and when run at the pressure which the maker recommends, the resultant will give the true efficiency of the lamp, judged as a machine for converting electric energy into light ; and hence its efficiency is the ratio existing between the total amount of electric energy consumed during its life, and the total quantity of light given out during its life, so that

total energy = mean watts × hours of life ;
total light = mean candle-power × hours of life ;

$$\therefore \text{efficiency} = \frac{\text{watt-hours}}{\text{candle-power hours}}.$$

This efficiency may be expressed as so many watts per candle-power. If the lamp be run at other pressures than what is recommended by the manufacturer, whether slightly above or slightly below, different efficiencies will be obtained. The relations between working pressure and efficiency provide a subject for most interesting and elaborate calculations, and forms a neat example of the "maxima and minima" order of problems, because, as mentioned previously, running a lamp at a slightly higher pressure than what it is made for will give a large increase of light at the early part of its life, but the light will diminish rapidly, and the life of the lamp will be considerably shortened.

The following data gives the results of experiments that have been made with the greatest care and every precaution by Messrs. Siemens and Halske, of Berlin, and they show in the most emphatic manner that those lamps that are run with a small initial power are not efficient, and that those which consume a smaller initial power are the most efficient in the long run :

(To be continued.)

ON THE ELECTRIC LIGHT OF LIGHTHOUSES.*

EXPERIMENTS MADE BY THE LIGHTHOUSE DEPARTMENT OF FRANCE.

BY ANDRÉ BLONDEL.

(Concluded from page 107.)

Choice of Carbons, Diameter, and Separation.—For the same reason as with continuous currents, we employ the hardest possible carbons. The specific resistance of "Carre" carbons, which give excellent results, increases with the diameter ; it may be estimated on an average at 7,000 to 8,000 microhms. The smallest admissible dimensions, and consequently the most satisfactory, are indicated in the preceding table. They correspond to currents of 0·315, 0·25, and 0·24 amperes per square millimetre.

This current density might be further increased, and consequently the diameter diminished, by the employment of carbons lightly coated with copper (1/5th mm.), so that the melting of the copper may not produce any accidental shunt circuit, followed by extinction.†

* Paper read before the International Maritime Congress, London meeting, July, 1893.

† The greatest difficulty is to manufacture carbons of diameter greater than 20mm. sufficiently homogeneous to support the passage of the current without cracking transversely. The researches on this point made by M. Carre and Le Carbone Co. encourage us to hope for some success shortly in this direction.

The arc cannot be made longer than 10 mm. to 15 mm. without producing a large flame; besides, we cannot increase the distance apart without at the same time increasing the difference of potential, and consequently the work expended at constant current. Geometrically it appears sufficient to separate the parts raised to the maximum brightness until the distance is equal to half the diameter of the terminal faces, or about a quarter the diameter of the carbons, that is to say, to 6mm for arcs of 100 amperes. The two foci of bi focal lenses being at 1cm. apart, we are thus assured that the focal rays pass through the incandescent portions. The corresponding pressure, which is about 45 volts, has been allowed for all the currents, in order not to complicate the service, whilst realising the maximum power of the De Meritens machines at the speed of 550 revolutions. To determine directly the best distance between the carbons, a series of experiments should be made with the same intensity of current. These might be undertaken with the help of the new alternators with variable exciting current, whilst hitherto it has been impossible to make them with the De Meritens machine. The measurements made on this point at the Lighthouse Department, France, have only availed to establish that in bi-focal lenses, and with magneto machines, the actual

Magneto Electric Machines of De Meritens.

It is known that these machines comprise five armature rings, each revolving in the interior of a corresponding ring of electro-magnets. The coils are equal in number to the magnet poles that is to say, 16 in the French lighthouses (Type C) and 24 in the English lighthouses (Type 1)* They constitute so many independent elements that can be coupled at will in series or in parallel.

In the French lighthouses, according to different experiments, the old coupling, corresponding to a speed of 900 revolutions, has been definitely abandoned, this speed being too high by reason of the defective mode of lubrication of the machines, and it has been reduced to about 450 (raised more recently to 550). In these conditions each machine is composed of two circuits having each five groups of eight coils in series that is to say, the half of each ring coupled in parallel. These two circuits each end in two insulated rings, keyed on to the shaft of the machine. At the speed of 450 revolutions each machine is capable of giving, with a difference of potential of 40 volts, a current of 22·5 or of 50 amperes, according as one is used or two. At the speed of 550 revolutions we obtain the same intensities with a pressure of 55 volts.

currents [illegible] higher than those that would be obtained by increasing the separation, as the following table shows:

Diameter of the carbons.	Distance apart.	Intensity.	Pressure.	Electric power. Apparent.	Electric power. Corrected.	Luminous power.	Efficiency per watt.
mm.	mm.	amp.	volts.				
16	5	50	45	2,250	2,140	1,925,000	900
16	15	45	50	2,250	2,140	1,140,000	532
10	4	25	45	1,125	1,069	1,110,000	1,032
10	[illegible]	[illegible]	47	1,080	1,026	1,014,000	980
10	8	19	52	988	939	720,000	771

But these conclusions would not necessarily apply to different types of machine or optical apparatus.

Alternate Current Machines. Properties and Results Obtained.

According to the preceding remarks the electric conditions which a type of alternator must fulfil in order to be perfect for the service of a French lighthouse are as follows: To furnish at will currents of from 25 to 100 amperes; to bear without disturbance a sudden or prolonged short circuit; to enable the power to vary in the neighbourhood of the normal condition in the same sense as the intensity or that it shall pass through a maximum; to give an open circuit an E.M.F. of at least 70 volts, and, lastly, to have a frequency of at least 40 to 50 periods per second.

We shall now see how the different machines answer to this programme, beginning with the De Meritens machine as the best known, and, we may almost say, as the only one hitherto employed.*

Properties.—The periodic curves of Fig. 10 represent the laws according to which the induced E.M.F., the difference of potential at the terminals, and the intensity under different conditions vary during each period. The well marked double summit of the E.M.F. arises simply from the fact that the magnet poles are much wider than those of the armature. It disappears from the curves of intensity as soon as the current becomes somewhat strong.

Currents.—Fig. 15 represents the external characteristics of a complete machine at the speed of 450 revolutions, and consequently the series of currents that it can furnish at the terminals when the external resistance is varied.†

When a half machine is working alone, the conditions in which the eight bobbins utilised for each ring are placed are not exactly the same as when the two circuits are closed because of their mutual induction. This difference shows itself in a certain reduction of intensity. Whilst we obtain 25 amperes at 40 volts in each circuit when they are working together, we only obtain 22·5 amperes at 40 volts with one of them separately.

Power.—The apparent power, E I, varies according to a law represented as a function of the intensity of the current by two curves deduced from the characteristics Fig. 13. These curves have maxima corresponding to the two normal currents, 25 and 50 amperes. If we neglect subordinate phenomena of small importance, these currents correspond also approximately to the maxima of the mechanical power required from the motor. Also, owing to the important effects of hysteresis, and, above all, of

* Zipernowski's machines have been, nevertheless, recently installed at the Campan Lighthouse.

* D. V. Reports on the experiments at South Foreland. Part II., p. 20.

† The curves have been drawn taking for the resistance either a liquid rheostat or an arc. No sensible difference has been found between the two cases, although the power expended in the arc is no longer equal to the apparent power, as we have said above. The characteristic of supply at the terminals of the lamp is deduced from the former by subtracting from its ordinates the pressure absorbed by the resistance of the wires, neglecting self-induction. The regulating coil in series absorbs less than 1 volt.

Foucault currents, which arise in the armature and the electro magnets, through their being insufficiently laminated, this power varies very little from one current to the other and this further contributes to increase the steadiness, and to destroy any tendency to racing when the current is interrupted. The work on open circuit is, in fact, not less than 2 h.p.

Efficiency.—The considerable losses cause the efficiency to be wretched with small loads but they diminish very rapidly as the armature is traversed by a current, its magnetic action being, as we know, opposed to that of the electromagnets. Experiment made long ago at the Lighthouse Establishment, France gave, with the 50 ampere current, an efficiency of 0·77, which is not far from the 0·80 obtained at South Foreland.* For the current of 25 amperes the power is one half less, the subsidiary actions being on the contrary increased, and it is not surprising, then, that the efficiency is reduced to about 0·54.

Coupling.—The two De Meritens machines of a lighthouse may be coupled in parallel either by means of mechanical gearing or electrically, as Dr. Hopkinson first showed to be possible in his lecture before the Institution of Civil Engineers, and as Prof. W. Grylls Adams first showed practically in his experiments with the De Meritens machines at the South Foreland. Since this demonstration electrical coupling has been tried in a certain number of French and other lighthouses. If the pulleys are quite equal, and the belts equally and moderately stretched, the two machines synchronise of themselves, and retain their synchronism for an indefinite time.

Without giving up the benefits of electrical coupling, the chief of which is its not demanding any stoppage of the machine, it is prudent, looking at the disadvantageous conditions in which the synchronisation is produced, to have a mechanical method of coupling in reserve to which recourse can be had whenever the former appears insufficient;† that is a solution adopted in the new installation of the lighthouse at La Hève. The mechanical coupling adopted, made by the house of Sautter, Harlé and Co., is combined with a system of two loose pulleys placed between the fixed pulleys of the dynamos, and it can be operated without interrupting the working of the machine which is already in operation.

Advantages and Defects.—These machines, which for 12 years have not given rise to any accident, are remarkable above everything for their qualities of safety and regularity. Their mode of lubrication might be easily improved. From the electrical point of view, thanks to their great mechanical inertia, to the constancy of their magnetic field,‡ and the form of their characteristic, they give very steady arcs, and support without inconvenience a short circuit of which the intensity is not above 80 amperes. The subsidiary actions themselves, as we have seen, are beneficial in certain respects. As to the efficiency, it is not much inferior at the current of 50 amperes to what can be obtained with machines of such small power. The small value with the 25 ampere current only employed during a small part of the year (20 per cent. at the La Hève Lighthouse) does not play a very important part in the annual expense, and besides, all the machines with two currents show always more or less the same defects.

The only defects which may indisputably be ascribed to the De Meritens machines arise from the employment of permanent magnets. These are their cumbrous size and their price. The price (9,000f.) is very high compared with that at which we find to-day the equivalent alternators of commerce (from 3,000f., including the exciter). It is for this reason that a type of machine has been sought with alternate currents presenting the same electrical properties, and, therefore, the same practical qualities.

Alternate Current Dynamos intended to Replace the Magnetos of De Meritens.

First Attempts.—The first solution, which consisted in the employment of a single machine capable of furnishing three currents of 25, 50, and 100 amperes, by a simple modification of the exciting machine was attempted in 1889 without success. The machine was of the Siemens type, properly so called, with an apparent internal resistance extremely small. Its characteristic was almost horizontal, and could give no stability; nevertheless, three good characteristics, with sufficient slope, might have been obtained by the help of the machine by exciting it at 70 volts at least on open circuit, and interpolating in the circuit self-induction coils proportioned to each current. The latter play, in fact, for alternate-current machines, the same part as the rheostat does for continuous current machines, with this difference, that they absorb scarcely any energy. Several attempts made in this direction have given good results, and have shown that we may obtain in this way not only three sloping characteristics, but also three currents of maximum power at 25, 50, and 100 amperes without the intensity and short circuit ever passing $1\frac{1}{2}$ to 2 times the normal intensity. Thanks to this contrivance, any alternator whatever of the ordinary types might supply an arc lighthouse with steadiness, but the efficiency would be unsatisfactory with lower currents, and a machine has been preferred, as said above, with two currents; only it was proposed, as said above, to obtain them by two independent circuits, as in the De Meritens machines, to which the attendants are accustomed.

Alternator without Core, having Separate Exciter.—The Siemens type without core was that which at the outset appeared to lend itself best to this combination, because the subsidiary action, already weak in it, enables us easily to calculate beforehand the self induction of the machine, and to avoid the reactions of one of the circuits on the other.

A machine of this type established according to the programme sketched out was constructed by the "L'Eclairage Electrique" Company on the plans of M. Labour, their engineer, and underwent in 1891 prolonged trials at the Lighthouse Establishment (France). The alternator and its exciter, Fig. 16, are mounted side by side, so that their two shafts may be coupled and driven by a single pulley carried by the shaft of the alternator. To facilitate the throwing in and out of gear, the shaft carries a loose pulley with a grease cup. The exciter is a Rechniewsky continuous current machine, excited in series, whose armature is toothed so as to reduce to a minimum the magnetic resistance of the air gap, and consequently the cost of exciting, and of which the electromagnets are built up of sheets in order to reduce to a minimum the Foucault currents and the consequent loss of energy. The Siemens-Labour alternator, similar in type to the ordinary Siemens in its general arrangements, is distinguished from it by the manner in which the armature coils are mounted and wound. These are made with a conductor, not of thin plates, but of insulated wires, which allows the number of turns to be increased, and the losses by Foucault currents to be diminished. The coils are eight in number, like the pairs of magnet poles. They form two circuits, each comprising four of them (two in series and two in shunt), and leading to three collecting rings, of which one forms a common return.

To obtain in this machine a sufficient self induction, as well as the condition of maximum power, a great quantity of copper must be put in the armature, which has consequently a great resistance, and the magnetic field must be reduced to a comparatively small value. The following statement includes the principal data of its construction, which designedly departs from ordinary conditions:

Data of Construction.—Speed, 800 revolutions; frequency, 53·33 periods. Armature wire of 1·8mm., 120 turns per coil; resistance and self induction of one circuit, 0·41 ohms and 0·006 henrys. Electromagnets, wires of 4mm. 130 turns per electro; resistance, 0·85 ohms. Air gap length 19mm.; section per coil, 73 square centimetres. Magnetic field, about 1,600 C.G.S. Intensity of exciting current, 10 to 11 amperes.

The industrial efficiency, measured with much care, determining the losses, when unloaded, by the aid of a standardised electric motor, has been found equal to 61 per cent. at a current of 25 amperes and 45 volts (one circuit only), and 71·6 per cent. at a current of 50 amperes and 45 volts (two circuits in parallel). The periodic curves of Fig. 11, and the characteristics of Fig. 14 relative to one and two circuits coupled, exhibit the properties of this machine, which differ little, as we see, from those of the

---

The extinction of the arc takes place generally when the pressure at the terminals of the regulator becomes more than 50 volts. The characteristic does not differ much from an ellipse, as Fig. 13 shows. We may then apply with sufficient approximation, as Dr. Hopkinson proposes, the ordinary formula of alternate current (Joubert's formula).

$$I = \frac{E}{\sqrt{R^2 + \left(\frac{2\pi L}{T}\right)^2}}$$

But the self induction, L, which figures in this formula is not constant, in fact we deduce from the curve; knowing the internal resistance of the machine, $r = 0·12\omega$, the following values for the inductive resistance $\frac{2\pi L}{T}$:—

For $I = 25$ amperes $\frac{2\pi L}{T} = 1·13\omega$

„ $I = 50$ „ $\frac{2\pi L}{T} = 0·86$

„ $I = 78$ „ (short circuit) $\frac{2\pi L}{T} = 0·85$

The value of 0·86 corresponds to a self-induction $\frac{0·86}{2·60} = 0·0024$ henry for the complete machine.

* This figure is the apparent efficiency; it ought to be reduced by 5 per cent. to take into account the factor of mean power (0·95) applicable to the arc.

† A more exhaustive study (*Lumière Electrique*, vol. 46, p. 460) shows that with equal retardation the difference of load produced, and, consequently, the corrective action maintaining the synchronism are so much weaker as the normal current is greater compared with the current that the machine can supply on short circuit. Now, in the De Meritens machine the former reaches about two-thirds of the latter, a figure comparatively high. The suitability of these machines for coupling is therefore not great, and the synchronisation might be prevented without much difficulty; in fact, it seems to become impossible when the diameters of the pulleys are in the least degree different, or the belts not equally stretched, of which we have recently had an example at Cape Gris-nez. The complete electrical coupling of the machine with a half machine, practised during some time in order to obtain a current of 75 amperes, has given no very satisfactory result. It gave rise to well marked periodic oscillations, which led to its abandonment.

‡ One of the objections that might be raised against the employment of De Meritens magnetos is that their proper working depends upon the preservation of the magnetism of their magnets. We should be justified, in truth, in having some doubts on this point, seeing that the current of the armature produces a demagnetising effect, and that certain "Alliance" machines (Port Said Lighthouse) have been completely demagnetised. But, in point of fact, except in certain special cases in which a magnet had been recognised as inferior from the outset, no sensible loss of magnetism has been noticed during 10 years in the machines of French lighthouses.

De Meritens magnetos. We might then have found immediately in this machine a satisfactory solution of the problem, if it had not shown certain defects of some importance—viz., the extended form of the two machines together with difficulties of electric coupling arising from the small inertia of the turning parts, and above all, the excessive heating of the armature.

Self Exciting Alternator with Core.—We might remedy without difficulty the greater part of these defects, but it has been preferred to attempt, for comparison, another type of alternator with a core to the armature, which enables such self induction to be obtained as may be desired, and which, owing to the employment of thin iron sheets, may give a better efficiency.

The "L'Eclairage Electrique" Company has constructed a new machine answering to these requirements, after the plans of their engineer, M. Labour. This alternator, Figs. 17 and 17B, shows a model and form similar to those of the Rechniewsky dynamos of the multipolar type. But the armature, in the form of a toothed ring, carries a winding of a special kind; each coil is, as Fig. 18 shows, a kind of flat bobbin formed of concentric turns wound in a number of grooves. Thanks to this arrangement, which is quite new for alternators, and which produces an intimate proximity between the iron and the copper in each coil, we obtain a great economy in the exciting, at the same time as the strong reaction of the armature which is desired. The air gap showing no sensible variation, and the reaction of the armature coils taking place progressively, this machine produces no humming.

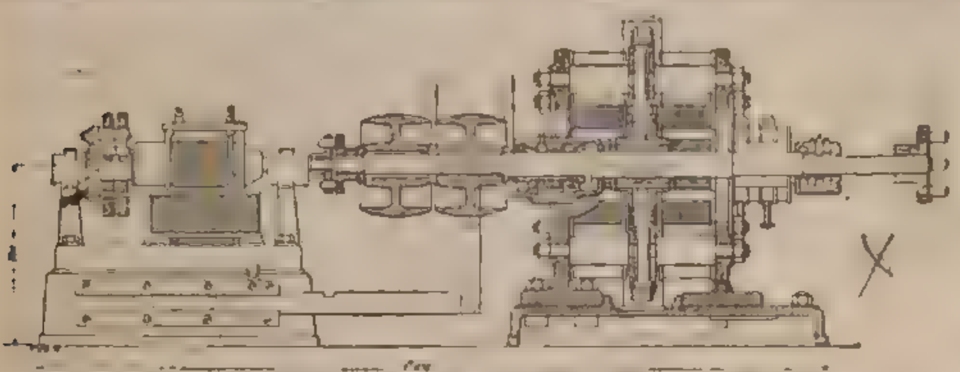

Fig. 16.

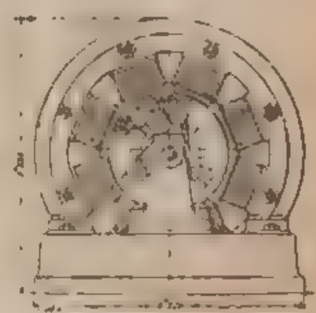

Fig. 17.

The electromagnets and the coils of the armature are still eight in number. The coils are coupled in two circuits, ending in three collecting rings. The principal data of construction are given below.

Data of Construction.—Speed, 800 revolutions. Frequency, 533 periods. Armature wire of 3·2mm. diameter, 36 turns per coil; resistance of one circuit, 0·164 ohms; 72 teeth—i.e., 9 per bobbin. Maximum induction, 7,280 C.G.S. Air gap, 5·5mm. Electromagnets, wire of 2·7mm. diameter, 260 turns per electro. Total resistance, 2·60 ohms. Exciting currents at the 25 ampere currents, I = 3·06 amperes and 3·77. Owing to the employment of the toothed ring, the expense for exciting is extraordinarily low (24 and 37 watts).

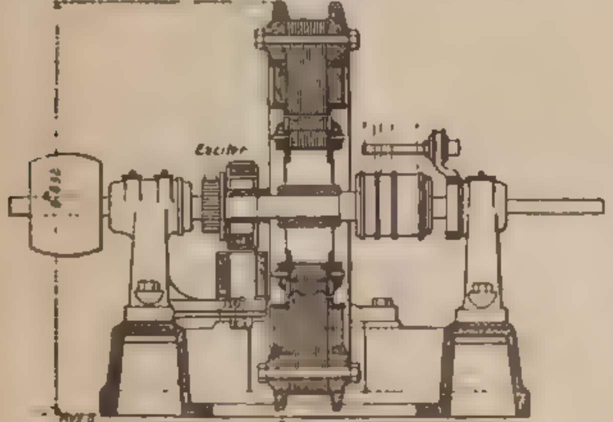

Fig. 17B.

The industrial efficiency, measured as in the case of the preceding machine, reaches the following figures, much superior to those of magnetos. One circuit alone, efficiency 72·2 per cent. Two circuits in parallel at 50 ampere current, 80·4 per cent.; 25 ampere current, obtained by the aid of a self induction coil, 74·5 per cent. The switchboard, Fig. 19, used for this last combination is remarkably simple, especially compared to that of Fig. 20. It was proposed chiefly to simplify the manner of exciting this alternator by the aid of a continuous current circuit, wrapped on the same armature and ending in a commutator placed at the opposite side to the alternate collector. But the reactions of the alternate current on the exciting current caused this arrangement to be abandoned after trial in favour of a small continuous current exciter placed immediately beside the armature, where the continuous current commutator was placed. The dimensions of the machine are not in this way increased. They are extremely small compared with the magnetos of De Meritens.

The periodic curves of Fig. 12 and the characteristics of Fig. 15 exhibit the properties of the machine, which, as we see, do not sensibly differ from those of the preceding machine. An excellent stability is obtained, the condition of maximum power is realised, and the intensity and short circuit is not much above the normal intensity. We may thus consider henceforward this machine as equivalent to the De Meritens magneto.

Comparison of Continuous and Alternate Currents.

This comparison, the elements for which have been furnished in the preceding chapters, should refer at once to the arc, the optical apparatus and the dynamos.

(1) *The Dynamos.*—The continuous current dynamos are satisfactory from the point of view of strength and safety. They show great economy in space and in cost compared to the De Meritens machines, but the steadiness of the arc has only been obtained at the cost of a loss of efficiency, the efficiency at the terminals of the lamp having been reduced to 0·58 or 0·65 at the 25 and 50 ampere currents.* On the contrary, the new alternators allow us to preserve the advantages of the De Meritens machines while costing a little more than the dynamos, and giving electrical efficiencies of 74 and 80 per cent. at the two currents considered. It is these machines, then, which appear at present likely to take the place of the De Meritens machines without any change in the remainder of the service.

But it is not to be forgotten that all the possible advantage obtainable from continuous current dynamos has not yet been obtained, and that by a suitable compounding we might probably realise a stability and efficiency superior to those hitherto obtained with these machines.

(2) *The Arc.*—In spite of the ingenious solenoid of MM. Sautter, Harlé and Cie., and the employment of the rheostat, the continuous current with the positive carbon below remains inferior in regularity to the alternate current arc. This may be seen from the following table, which sums up in a comparison the variations in illumination of the ray observed in the experiments of the central depôt.

Apparatus.	Current.	Relative variations of the luminous power.		
		With current of 25 amperes.	With current of 30 amperes.	With current of 100 amperes.
Feu éclair type, 1892 ..	alternate	Per cent. 30 to 36	Per cent. 40 to 50	Per cent. 50 to 70
Feu éclair type, 1892	continuous	1·42	1·65	1·87

This inferiority is especially important with feux-éclairs, in which the lamp turns with the apparatus, and where it is consequently necessary that the figure should be as symmetrical as possible in order that successive flashes may be of equal power. The arc with positive carbon uppermost would give in this respect more favourable results.

(3) *Apparatus.*—The present bi-focal apparatus is combined for the use of the alternate current. Experiments made at La Hève (*feu-éclair*) with an apparatus of 0·60m. diameter, in four panels, have given, with almost equal currents, luminous powers and efficiencies much superior with alternate currents to those obtained with continuous currents, as is shown by the following table.†

* It is just to observe, nevertheless, that at the lighthouse of La Hève, where the definitive experiments will take place, the steadying resistances may be suppressed in large measure owing to the resistance of the cables.

† We have not quoted in this table the figures of 1,800,000 becs, or 332 per watt, mentioned above, for the current of 98 amperes at 57 volts, because the 500,000 becs of increase were only gained by the excessive diminution of the negative carbon (18 mm. instead of 23), with which such a condition could not be maintained. It produces, also, too great irregularity, the power varying from 580,000 to 3,200,000 becs, while in the normal *régime* the power only varied from 1,300,000 to 3,130,000 becs.

heated also if it were connected to a source of a steady potential. In such a case electricity would be carried away from the button by the freely movable carriers or particles flying about, and the quantity of electricity thus carried away might be sufficient to bring the button to incandescence by its passage through the latter. But the bombardment could not be of great importance in such case. For this reason, it would require a comparatively very great supply of energy to the button to maintain it at incandescence with a steady potential. The higher the frequency of the electric impulses, the more economically can the button be maintained at incandescence. One of the chief reasons why this is so is, I believe, that with impulses of very high frequency there is less exchange of the freely movable carriers around the electrode, and this means that in the bulb the heated matter is better confined to the neighbourhood of the button. If a double bulb,

Incandescence or Phosphorescence of Rarefied Gas.

as illustrated in Fig. 30, be made, comprising a large globe, B, and a small one, b, each containing, as usual, a filament, f, mounted on platinum wire, w and w_1, it is found that if the filaments, $f\,f$, be exactly alike, it requires less energy to keep the filament in the globe, b, at a certain degree of incandescence than that in the large globe, B. This is due to the confinement of the movable particles around the button. In this case it is also ascertained that the filament in the small globe, b, is less deteriorated when maintained a certain length of time at incandescence. This is a necessary consequence of the fact that the gas in the small bulb becomes strongly heated, and therefore a very good conductor, and less work is then performed on the button, since the bombardment becomes less intense as the conductivity of the gas increases. In this construction of course the small bulb becomes very hot, and when it reaches an elevated temperature the convection and radiation on the outside increase. On another occasion I have shown bulbs in which this drawback was largely avoided. In these instances a very small bulb containing a refractory button was mounted in a large globe and the space between the walls of both was highly exhausted.

Luminosity of Gas at Ordinary Pressure.

The outer large globe remained comparatively cool in such constructions. When the large globe was on the pump, and the vacuum between the walls maintained permanent by the continuous action of the pump, the outer globe would remain quite cold, while the button in the small bulb was kept at incandescence. But when the seal was made, and the button in the small bulb maintained incandescent some length of time, the large globe, too, would become warmed. From this I conjecture that if vacuous space (as Prof. Dewar finds) cannot convey heat, it is so merely in virtue of our rapid motion through space, or, generally speaking, by the motion of the medium relatively to us, for a permanent condition could not be maintained without the medium being constantly renewed. A vacuum cannot, according to all evidence, be permanently maintained around a hot body.

In these constructions before mentioned the small bulb inside would, at least, in the first stages, prevent all bombardment against the outer large globe. It occurred to me then to ascertain how a metal sieve would behave in this respect, and several bulbs, as illustrated in Fig. 31, were prepared for this purpose. In a globe, b, was mounted a thin filament, f (or button), upon a platinum wire, w, passing through a glass stem and leading to the outside of the globe. The filament, f, was surrounded by a metal sieve, s. It was found in experiments with such bulbs that a sieve with wide meshes apparently did not in the slightest affect the bombardment against the globe, b. When the vacuum was high the shadow of the sieve was clearly projected against the globe and the latter would get hot in a short while. In some bulbs the sieve, s, was connected to a platinum wire sealed in the glass. When this wire was connected to the other terminal of the induction coil (the E.M.F. being kept low in this case), or to an insulated plate, the bombardment against the outer globe, b, was diminished. By taking a sieve with fine meshes the bombardment against the globe, b, was always diminished, but even then, if the exhaustion was carried very far, and when the potential of the transformer was very high, the globe, b, would be bombarded and heated quickly, though no shadow of the sieve was visible owing to the smallness of the meshes. But a glass tube or other continuous body mounted so as to surround the filament did entirely cut off the bombardment, and for a while the outer globe, b, would remain perfectly cold. Of course when the glass tube was sufficiently heated the bombardment against the outer globe, could be noted at once. The experiments with these bulbs seemed to show that the speeds of the projected molecules or particles must be considerable (though quite insignificant when compared with that of light), otherwise it would be difficult to understand how they could traverse a fine metal sieve without being affected, unless it were found that such small particles or atoms cannot be acted upon directly at measurable distances. In regard to the speed of the projected atoms, Lord Kelvin has recently estimated it at about one kilometre a second or thereabouts in an ordinary Crookes bulb. As the potentials obtainable with a disruptive discharge coil are much higher than with ordinary coils, the speeds must of course be much greater when the bulbs are lighted from such a coil. Assuming the speed to be as high as five kilometres and

Showing the Effect of Confining the Gas Around the Electrode.

Showing the Inefficiency of a Metal Screen.

uniform through the whole trajectory, as it should be in a very highly exhausted vessel, then if the alternate electrifications of the electrode would be of a frequency of 5,000,000, the greatest distance a particle could get away from the electrode would be one millimetre, and if it could be acted upon directly at that distance, the exchange of electrode matter or of the atoms would be very slow, and there would be practically no bombardment against the bulb. This, at least, should be so, if the action of an electrode upon the atoms of the residual gas would be such as upon electrified bodies which we can perceive. A hot body enclosed in an exhausted bulb produces always atomic bombardment, but a hot body has no definite rhythm, for its molecules perform vibrations of all kinds.

If a bulb containing a button or filament be exhausted as high as is possible with the greatest care and by the use of the best artifices, it is often observed that the discharge cannot at first break through, but after some time, probably in consequence of some changes within the bulb, the discharge finally passes through and the button is rendered incandescent. In fact, it appears that the higher the degree of exhaustion the easier is the incandescence produced. There seems to be no other causes to which the incandescence might be attributed in such case except to the bombardment or similar action of the residual gas, or of particles of matter in general. But if the bulb be exhausted with the greatest care, can these play an important part? Assume the vacuum in the bulb to be tolerably perfect, the great interest then centres in the question, Is the medium which pervades all space continuous or atomic? If atomic, then the heating of a conducting button or filament in an exhausted vessel might be due largely to ether bombardment, and then the heating of a conductor in general through which currents of high frequency or high potential are passed must be modified by the behaviour of such medium; then also the skin effect, the apparent increase of ohmic resistance, etc., admit partially, at least, of a different explanation.

It is certainly more in accordance with many phenomena observed with high frequency currents to hold that all space is pervaded with free atoms rather than to assume that it is devoid of these, and dark and cold, for so it must be if filled with a continuous medium, since in such there can be neither heat nor light. Is then energy transmitted by independent carriers or by the vibration of a continuous medium? This important question is

by no means as yet positively answered. But most of the effects which are here considered, especially the light effects, incandescence or phosphorescence, involve the presence of free atoms, and would be impossible without these.

In regard to the incandescence of a refractory button (or filament) in an exhausted receiver, which has been one of the subjects of this investigation, the chief experiences which may serve as a guide in constructing such bulbs may be summed up as follows: (1) The button should be as small as possible, spherical, of a smooth or polished surface, and of refractory material which withstands evaporation best. (2) The support of the button should be very thin and screened by an aluminium and mica sheet, as I have described on another occasion. (3) The exhaustion of the bulb should be as high as possible. (4) The frequency of the currents should be as high as practicable. (5) The currents should be of a harmonic rise and fall, without sudden interruptions. (6) The heat should be confined to the button by enclosing the same in a small bulb or otherwise. (7) The space between the walls of the small bulb and the outer globe should be highly exhausted.

Most of the considerations which apply to the incandescence of a solid just considered may likewise be applied to phosphorescence. Indeed, in an exhausted vessel the phosphorescence is, as a rule, primarily excited by the powerful beating of the electrode stream of atoms against the phosphorescent body. Even in many cases where there is no evidence of such a bombardment, I think that phosphorescence is excited by violent impacts of atoms which are not necessarily thrown off from the electrode, but are acted upon from the same inductively through the medium or through chains of other atoms. That mechanical shocks play an important part in exciting phosphorescence in a bulb may be seen from the following experiment. If a bulb constructed as that illustrated in Fig. 10 be taken, and exhausted with the greatest care so that the discharge cannot pass, the filament, *f*, acts by electrostatic induction upon the tube, *t*, and the latter is set in vibration. If the tube, *o*, be rather wide, about an inch or so, the filament may be so powerfully vibrated that whenever it hits the glass tube it excites phosphorescence. But the phosphorescence ceases when the filament comes to rest. The vibration can be arrested and again started by varying the frequency of the currents. Namely, the filament has its own period of vibration, and if the frequency of the currents is such that there is resonance, it is set easily vibrating, though the potential of the currents be small. I have often observed that the filament in the bulb is destroyed by such mechanical resonance. The filament vibrates, as a rule, so rapidly that it cannot be seen, and the experimenter may at first be mystified. When such an experiment as the one described is carefully performed, the potential of the currents need be extremely small, and for this reason I infer that the phosphorescence is then due to the mechanical shock of the filament against the glass, just as it is produced by striking a loaf of sugar with a knife. The mechanical shock produced by the projected atoms is easily noted when a bulb containing a button is grasped in the hand, and the current turned on suddenly. I believe that a bulb could be shattered by observing the conditions of resonance.

In the experiment before cited it is, of course, open to say that the glass tube, upon coming in contact with the filament, retains a charge of a certain sign upon the point of contact. If now the filament again touches the glass at the same point while it is oppositely charged, the charges equalise under evolution of light. But nothing of importance would be gained by such an explanation. It is unquestionable that the initial charges given to the atoms or to the glass play some part in exciting phosphorescence. So, for instance, if a phosphorescent bulb be first excited by a high frequency coil by connecting it to one of the terminals of the latter and the degree of luminosity noted, and then the bulb be highly charged from a Holtz machine by attaching it preferably to the positive terminal of the machine, it is found that when the bulb is again connected to the terminal of the high frequency coil, the phosphorescence is far more intense. On another occasion I have considered the possibility of some phosphorescent phenomena in bulbs being produced by the incandescence of an infinitesimal layer on the surface of the phosphorescent body. Certainly, the impacts of the atoms are powerful enough to produce intense incandescence by the collisions, since they bring quickly to a high temperature a body of considerable bulk. If any such effect exists, then the best appliance for producing phosphorescence in a bulb which we know so far is a disruptive discharge coil giving an enormous potential with but few fundamental discharges, say 25-30 per second, just enough to produce a continuous impression upon the eye. It is a fact that such a coil excites phosphorescence under most any condition and at all degrees of exhaustion, and I have observed effects which appear to be due to phosphorescence even at ordinary pressures of the atmosphere, when the potentials are extremely high. But if phosphorescent light is produced by the equalisation of charges of electrified atoms (whatever this may mean ultimately), then the higher the frequency of the impulses, or alternate electrifications, the more economical will be the light production. It is a long known and noteworthy fact that all the phosphorescent bodies are poor conductors of electricity and heat, and that all bodies cease to emit phosphorescent light when they are brought to a certain temperature. Conductors, on the contrary, do not possess this quality. There are but few exceptions to the rule. Carbon is one of them. Becquerel noted that carbon phosphoresces at a certain elevated temperature preceding the dark red. This phenomenon may be easily observed in bulbs provided with a rather large carbon electrode (say, a sphere of six millimetres diameter). If the current is turned on after a few seconds a snow white film covers the electrode, just before it gets dark red. Similar effects are noted with other conducting bodies, but many scientific men will probably not attribute them to true phosphorescence. Whether true incandescence has anything to do with phosphorescence excited by atomic impact or mechanical shocks still remains to be decided, but it is a fact that all conditions which tend to localise and increase the heating effect at the point of impact are almost invariably the most favourable for the production of phosphorescence. So, if the electrode be very small, which is equivalent to saying in general that the electric density is great, if the potential be high, and if the gas be highly rarefied, all of which things imply high speed of the projected atoms, or matter, and consequently violent impacts, the phosphorescence is very intense. If a bulb provided with a large and small electrode be attached to the terminal of an induction coil, the small electrode excites phosphorescence while the large one may not do so, because of the smaller electric density and hence smaller speed of the atoms. A bulb provided with a large electrode may be grasped with the hand while the electrode is connected to the terminal of the coil, and it may not phosphoresce; but if instead of grasping the bulb with the hand, the same be touched with a pointed wire, the phosphorescence at once spreads through the bulb, because of the great density at the point of contact. With low frequencies it seems that gases of great atomic weight excite more intense phosphorescence than those of smaller weight, as, for instance, hydrogen. With high frequencies the observations are not sufficiently reliable to draw a conclusion. Oxygen, as is well known, produces exceptionally strong effects, which may be in part due to chemical action. A bulb with hydrogen residue seems to be most easily excited. Electrodes which are most easily deteriorated produce more intense phosphorescence in bulbs, but the condition is not permanent because of the impairing of the vacuum and the deposition of the electrode matter upon the phosphorescent surfaces. Some liquids, as oils, for instance, produce magnificent effects of phosphorescence (or fluorescence?), but they last only a few seconds; so if a bulb have a trace of oil on the walls, and the current is turned on, the phosphorescence only persists for a few moments until the oil is carried away. Of all bodies so far tried, sulphide of zinc seems to be the most susceptible to phosphorescence. Some samples obtained through the kindness of Prof. Henry, in Paris, were employed in many of these bulbs. One of the defects of this sulphide is that it loses its quality of emitting light when brought to a temperature which is by no means high. It can therefore be used only for feeble intensities. An observation which might deserve notice is that when violently bombarded from an aluminium electrode it assumes a black colour, but, singularly enough, it returns to the original condition when it cools down.

The most important fact arrived at in pursuing investigations in this direction is that in all cases it is necessary, in order to excite phosphorescence with a minimum amount of energy, to observe certain conditions. Namely, there is always, no matter what the frequency of the currents, degree of exhaustion and character of the bodies in the bulb, a certain potential (assuming the bulb excited from one terminal) or potential difference (assuming the bulb to be excited with both terminals) which produces the most economical result. If the potential be increased, considerable energy may be wasted without producing any more light, and if it be diminished, then again the light production is not as economical. The exact condition under which the best result is obtained seems to depend on many things of a different nature, and it is yet to be investigated by other experimenters; but it will certainly have to be observed when such phosphorescent bulbs are operated if the best results are to be attained.

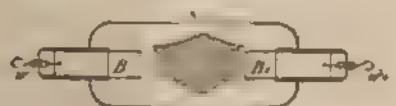
Coming now to the most interesting of these phenomena, the incandescence or phosphorescence of gases, at low pressures or at the ordinary pressure of the atmosphere, we must seek the explanation of these phenomena in the same primary causes, that is, in shocks or impacts of the atoms. Just as molecules or atoms beating upon a solid body excite phosphorescence in the same or render it incandescent, so when colliding among themselves they produce similar phenomena; but this is a very insufficient explanation, and concerns only the crude mechanism. Light is produced by vibrations which go on at a rate almost inconceivable. If we compute from the energy contained in the form of known radiations in a definite space the force which is necessary to set up such rapid vibrations, we find that though the density of the ether be incomparably smaller than that of any body we know—even hydrogen—the force is something surpassing comprehension. What is this force, which in mechanical measure may amount to thousands of tons per square inch? It is electrostatic force in the light of modern views. It is impossible to conceive how a body of measurable dimensions could be charged to so high a potential that the force would be sufficient to produce these vibrations. Long before any such charge could be imparted to the body it would be shattered into atoms. The sun emits light and heat, and so does an ordinary flame or incandescent filament, but in neither of these can the force be accounted for if it be assumed that it is associated with the body as a whole. Only in one way may we account for it, namely, by identifying it with the atom. An atom is so small, that if it be charged by coming in contact with an electrified body and the charge be assumed to follow the same law as in the case of bodies of measurable dimensions, it must retain a quantity of electricity which is fully capable of accounting for these forces and tremendous rates of vibration. But the atom behaves singularly in this respect—it always takes the same "charge."

It is very likely that resonant vibration plays a most important part in all manifestations of energy in nature. Throughout space all matter is vibrating, and all rates of vibration are represented, from the lowest musical note to the highest pitch of the chemical

rays, hence an atom, or complex of atoms, no matter what its period, must find a vibration with which it is in resonance. When we consider the enormous rapidity of the light vibrations, we realise the impossibility of producing such vibrations directly with any apparatus of measurable dimensions, and we are driven to the only possible means of attaining the object of setting up waves of light by electrical means and economically—that is, to affect the molecules or atoms of a gas, to cause them to collide and vibrate. We then must ask ourselves—How can free molecules or atoms be affected?

It is a fact that they can be affected by electrostatic force, as is apparent in many of these experiments. By varying the electrostatic force we can agitate the atoms, and cause them to collide under evolution of heat and light. It is not demonstrated beyond doubt that we can affect them otherwise. If a luminous discharge is produced in a closed exhausted tube, do the atoms arrange themselves in obedience to any other but to electrostatic force acting in straight lines from atom to atom? Only recently I investigated the mutual action between two circuits with extreme rates of vibration. When a battery of a few jars (*c c*,

Electrostatic Action Between Primary and Secondary, with Extremely High Frequencies.



Carbon Deposit in Tube in a Magnetic Field

Fig. 32) is discharged through a primary P, of low resistance (the connections being as illustrated in Figs. 19*a*, 19*b*, 19*c*), and the frequency of vibration be many million, there are great differences of potential between points on the primary not more than a few inches apart. These differences may be 10,000 volts per inch, if not more, taking the maximum value of the E.M.F. The secondary, *s*, is therefore acted upon by electrostatic induction, which is in such extreme cases of much greater importance than the electro-dynamic. To such sudden impulses the primary, as well as the secondary, are poor conductors, and therefore great differences of potential may be produced by electrostatic induction between adjacent points on the secondary. Then sparks may jump between the wires and streamers become visible in the dark

vibrate as a whole. I am convinced that no discharge through a gas can vibrate. The atoms of a gas behave very curiously in respect to sudden electric impulses. The gas does not seem to possess any appreciable inertia to such impulses, for it is a fact that the higher the frequency of the impulses, with the greater freedom does the discharge pass through the gas. If the gas possesses no inertia then it cannot vibrate, for some inertia is necessary for the free vibration. I conclude from this that if a lightning discharge occurs between two clouds, there can be no oscillation, such as would be expected, considering the capacity of the clouds. But if the lightning discharge strike the earth, there is always vibration—in the earth, but not in the cloud. In a gas discharge each atom vibrates at its own rate, but there is no vibration of the conducting gaseous mass as a whole. This is an important consideration in the great problem of producing light economically, for it teaches us that to reach this result we must use impulses of very high frequency and necessarily also of high potential. It is a fact that oxygen produces a more intense light in a tube. Is it because oxygen atoms possess some inertia and the vibration does not die out instantly? But then nitrogen should be as good, and chlorine and vapours of many other bodies much better than oxygen, unless the magnetic properties of the latter enter prominently into play. Or, is the process in the tube of an electrolytic nature? Many observations certainly speak for it, the most important being that matter is always carried away from the electrodes and the vacuum in a bulb cannot be permanently maintained. If such process takes place in reality, then, again, must we take refuge to high frequencies, for with such electrolytic action should be reduced to a minimum, if not rendered entirely impossible. It is an undeniable fact that with very high frequencies, provided the impulses be of a harmonic nature, like those obtained from an alternator, there is less deterioration and the vacua are more permanent. With disruptive discharge coils there are sudden rises of potential and the vacua are more quickly impaired, for the electrodes are deteriorated in a very short time. It was observed in some large tubes, which were provided with heavy carbon blocks, B B_1, connected to platinum wires, *w* w_1 (as illustrated in Fig. 33), and which were employed in experiments with the disruptive discharge instead of the ordinary air gap, that the carbon particles under the action of the powerful magnetic field in which the tube was placed, were deposited in regular fine lines in the middle of the tube as illustrated. These lines were attributed to the deflection or distortion of the discharge by the magnetic field, but why the deposit occurred principally where the field was most intense did not appear quite clear. A fact of interest, likewise noted, was that the presence of a strong magnetic field increases the deterioration of the electrodes, probably by reason of the rapid interruptions it produces, whereby there is actually a higher E.M.F. maintained between the electrodes.

Some of the Designs Produced by Intermittent Discharges.

if the light of the discharge through the spark gap, *d d*, be carefully excluded. If now we substitute a closed vacuum tube for the metallic secondary, *s*, the differences of potential produced in the tube by electrostatic induction from the primary are fully sufficient to excite portions of it; but as the points of certain differences of potential on the primary are not fixed, but are generally constantly changing in position, a luminous band is produced in the tube, apparently not touching the glass, as it should if the points of maximum and minimum differences of potential were fixed on the primary. I do not exclude the possibility of such a tube being excited only by electro-dynamic induction, for very able physicists hold this view; but, in my opinion, there is as yet no positive proof given that atoms of a gas in a closed tube may arrange themselves in chains under the action of an electromotive impulse produced by electro-dynamic induction in the tube. I have been unable so far to produce striæ in a tube, however long, and at whatever degree of exhaustion—that is, striæ at right angles to the supposed direction of the discharge or the axis of the tube; but I have distinctly observed in a large bulb, in which a wide luminous band was produced by passing a discharge of a battery through a wire surrounding the bulb, a circle of feeble luminosity between two luminous bands, one of which was more intense than the other. Furthermore, with my present experience I do not think that such a gas discharge in a closed tube can vibrate—that is,

Much would remain to be said about the luminous effects produced in gases at low or ordinary pressures. With the present experiences before us we cannot say that the essential nature of these charming phenomena is sufficiently known. But investigations in this direction are being pushed with exceptional ardour. Every line of scientific pursuit has its fascinations, but electrical investigation appears to possess a peculiar attraction, for there is no experiment or observation of any kind in the domain of this wonderful science which would not forcibly appeal to us. Yet to me it seems, that of all the many marvellous things we observe, a vacuum tube, excited by an electric impulse from a distant source, bursting forth out of the darkness and illuminating the room with its beautiful light, is as lovely a phenomenon as can greet our eyes. More interesting still it appears when, reducing the fundamental discharges across the gap to a very small number and waving the tube about, we produce all kinds of designs in luminous lines. So, by way of amusement, I take a straight long tube, or a square one, or a square attached to a straight tube, and by whirling them about in the hand I imitate the spokes of a wheel, a Gramme winding, a drum winding, an alternate current motor winding, etc., Fig. 34. Viewed from a distance, the effect is weak and much of its beauty is lost; but being near, or holding the tube in the hand, one cannot resist its charm.

In presenting these insignificant results I have not attempted to arrange and co-ordinate them as would be proper in a strictly

scientific investigation in which every succeeding result should be a logical sequence of the preceding, so that it might be guessed in advance by the careful reader or attentive listener. I have preferred to concentrate my energies chiefly upon advancing novel facts or ideas which might serve as suggestions to others, and this may serve as an excuse for the lack of harmony. The explanations of the phenomena have been given in good faith and in the spirit of a student prepared to find that they admit of a better interpretation. There can be no great harm in a student taking an erroneous view, but when great minds err the world must dearly pay for their mistakes.

STAFFORD ELECTRIC LIGHTING.

REPORT BY DR. JOHN HOPKINSON, M.A., F.R.S., M.I.C.E., ETC.

I have carefully considered the conditions of the town of Stafford in regard to electric lighting, and have visited the town for the purpose of seeing the site upon which it appears to be best to erect the machinery, and the character of the demand for light in the town.

The town of Stafford presents both favourable and unfavourable conditions in regard to electric lighting. Coal is cheap, water for condensation is accessible, and it would be easy for the Corporation to combine in a measure their electric light staff and the staff employed in the production of gas; these conditions all tend to economy of production. On the other hand, the demand for electric light in the town is not likely to be very large, and there will be many consumers whose demand for a supply will last for a short time only, whose account will therefore be small, but for whom it will be necessary to incur considerable expenditure for plant.

The first point to be decided is the site upon which the generating machinery is to be placed. In this respect you are fortunate, inasmuch as you have an excellent site at the gasworks which is not likely to be required for the production of gas. This site presents the advantage that, if steam be used, the boilers can be utilised for the purpose of the gasworks when they are not required for the production of electric light. From this will result a considerable economy of coal and wages. The site, too, is in proximity to the district where at first the principal demand may be expected. I am therefore of opinion that there can be no doubt whatever that the gasworks site is the right site for you to adopt.

The site for the generating plant having been decided upon, the next question is, what is the right system of supply to adopt? The whole of the lighting which you will have to do at first is comprised within a distance of about 700 yards from the generating station. It is now well recognised by all electric light engineers that when the district to be lighted is so near to the generating station, the proper system to adopt is that with continuous currents at low pressure. The continuous current has the great advantage that with it accumulators may be used. These are continually becoming cheaper, and even at their present price they are of great service in small stations, such as yours will be, in enabling the machinery to be stopped during the greater part of the 24 hours, so economising the wages of the attendants, who otherwise would have to be present for the purpose of supplying a very few lights. They have also the advantage that they enable you to increase to a material extent the maximum output of the station, inasmuch as you are able to add the output of the accumulators to the output of the machinery. The continuous current has the further advantage that it is more readily applied to the supply of mechanical power. I should therefore advise you to adopt the continuous current, with the system of conductors known as the three-wire system, which enables you to materially increase the pressure at which you work, and therefore to diminish the size and cost of your conductors. I should also advise you to make use of accumulators. If at a future time a demand for electricity arises at a greater distance from the station, this would be met by putting down a battery in the neighbourhood of the demand, and charging the battery from the station directly, if the distance did not exceed a mile, by means of a transformer if it was more considerable. One question still remains—as to the motive power to be used. It has been suggested that gas-engines should be adopted. I have not the least doubt that a perfectly satisfactory result could be attained with gas engines. I should, however, prefer steam for two reasons—firstly, if gas-engines be used it is necessary to increase the number of accumulators employed, in order to secure that steadiness of light which is essential; accumulators, of course, are costly instruments, and it is not desirable to increase their numbers beyond what is really necessary. Secondly, on anything but a small scale steam is cheaper than gas.

In laying out a plant for an electric light station it is of the greatest importance to so arrange that in the first instance no more machinery is laid down than there is reasonable certainty will be required within a very short time, and on the other hand, that as the demand increases, extensions can be made without undoing work already done. You are under obligation to supply light within an area indicated in your provisional order, and with this area I should advise you to begin, putting down distributing conductors from your generating station along Gaolgate street and Greengate street, to the end of Bridge street, and laying a feeder from the generating station to the Market square, which is the point at which your greatest demand is likely to be found. From this system of distributors you will lay service conductors to the various consumers as may be required. The cost of these conductors will be seen from the annexed schedule. The amount of light which will be required in this area is of course, necessarily a matter of speculation: it is impossible to say how many of the shops will take it, as this may be governed partly even by fashion. If one shopkeeper chooses to take it, his neighbours will probably follow his example. I think, however, that you cannot do less than begin with three engines of about 100 i.h.p. each, each driving a dynamo machine working at about 240 volts. Each of these machines would be capable of giving a maximum of about 60 units per hour—that is, of supplying 900 16-c.p. lights, or a little more. Two of these machines would be at work at one time, the other being spare. In connection with these machines I would provide an accumulator capable of giving 46 units for three hours, or, if absolutely necessary, 88 units for one hour, bringing up the total normal supply to 166 units. In the schedule appended to this report will be found an estimate of the cost of this plant, from which it appears that the expenditure which I consider it is absolutely necessary for the Corporation to incur is £12,000. In this estimate it will be observed that there is an adequate allowance for contingencies, and that meters are not included. As, however, I think that further extensions will be speedily required, I should advise you to go to the Local Government Board for permission to borrow a larger sum though I would not advise you to order more plant in the first instance. An estimate should be prepared, conceived upon a somewhat wider basis, to justify the larger borrowing powers. This larger estimate I have no doubt would be soon justified by the actual execution of work, but there is no necessity for incurring the expenditure until the demand actually makes it necessary.

The present estimate, then, is for machinery, mains, and everything necessary for a supply of 166 kilowatts (units per hour), or for lighting 2,500 16-c.p. lamps at one time. This would probably permit twice as many lamps to be wired, as it is not likely that more than that proportion would be required at one time. An additional 120 kilowatts could be added by a capital outlay of about £5,500, and further additions in proportion.

In the second schedule is given the estimate of the expenses chargeable to revenue. The coal account is small, but it must be remembered that the great expense of coal in electric lighting is due to the short hours during which steam is used; in your case these hours will be extended by other uses for the steam. The repairs are estimated for an average of many years; they would at first be much less.

An estimate of annual receipts is difficult, and must of necessity be something of a guess. I will assume, however, that 100,000 units are paid for per annum—that is to say, that the output of the station is used for 600 hours in the year, a figure which I should hope would be exceeded. If that were so, the electric light would pay its way at an average charge of 4½d. per unit. At this price, electric light would cost the consumer about 30 per cent. more than gas.

An inspection of my estimate of annual expenses at once shows that the expense of supplying customers for many hours is not much greater than that of supplying them for very few. The profitable consumers are those whose demand is long. In other towns I have endeavoured to meet this by a method of charge partly by meter and partly by the maximum current which the consumer may take. When the time comes, I should advise you to adopt a similar system.

The conclusions at which I arrive are: That the electric lighting will certainly pay in Stafford, but that the profits will not be large as the business will be small; that the necessary outlay will be £12,000, but that the Local Government Board should be asked to sanction a loan of £20,000; that the system should be the three-wire direct current system, supplied by steam engines and a small battery of accumulators.

SCHEDULE I.

Two boilers, with mountings and injectors; Two economisers, each of 72 pipes; Steam and water pipes	£1,665
Three condensing engines, each of 100 i.h.p.; Three ejector condensers; Two steam-pumps for supplying water to condensers; Water pipes for pumps and condensers; Three belts	1,920
Three dynamos	990
Conductors: Distributors from engine house to junction of Greengate and Mill Bank; Feeders from engine house to Market square; 100 house connections	2,420
Accumulators	1,190
Switchboards and instruments	300
Buildings, including overhead traveller	2,000
	10,485
Contingencies, engineering expense, 15 per cent.	1,572
	£12,057

SCHEDULE II.

Interest and sinking fund, at 6 per cent.	£720
Coal, at 6lb. per unit	90
Oil, waste, and petty stores	20
Wages for running, exclusive of wages for repair	350
Repairs and maintenance, at 5 per cent.	600
	£1,780

LEGAL INTELLIGENCE.

HALL v. VAUGHAN

A case of considerable interest to electrical engineers came on for hearing at the Liverpool Assizes before Mr Justice Kennedy and a special jury on Thursday, August 3.

The plaintiffs, Messrs. A. Hall and Co., electrical engineers and contractors, of 1 and 11, South John street, Liverpool, sued Mr. John Vaughan, of Nannau, Dolgelly, to recover £665 damages for breach of contract. The circumstances appear to have been as follows. Early in December last plaintiffs supplied an estimate for lighting defendant's mansion, which was accepted; the plaintiffs immediately preparing to execute the work and contracting with other manufacturers for the turbine and generating plant. After a few weeks the defendant, without consulting Messrs. Hall, appointed as his consulting engineer a gentleman who happened to be a local contractor and competitor of the plaintiffs, and they immediately advised the defendant that having already undertaken the work and accepted all responsibility, they could not recognise the authority of any engineer to interfere with their arrangements, especially as they asked no payment until the whole was satisfactorily completed, and were willing that the defendant should have the installation examined and tested by any recognised consulting engineer before accepting same. The defendant, however, would not allow the plaintiffs to commence the erection of any part of the installation, and after delaying for considerable time, during which he sent enquiries for various particulars of the work to submit to his engineer, he finally refused to allow plaintiffs to carry out their contract, stating it would not be satisfactory. The plaintiffs therefore sued for damages, and when the case came on in court, the defendant's counsel, evidently appreciating plaintiffs' position, offered to compromise by paying £150 costs, and withdrawing any imputation upon plaintiffs' ability to carry out the work. This was accepted. The installation consisted of 120 16 c.p. incandescent lamps to be erected in the Hall, the generating plant being placed near a stream three-quarter mile distant from the Hall, and it included a special Victor turbine. As there was at all times an abundance of water and the attendant was to live in rooms adjoining the one containing the generating machines, the plaintiffs offered to carry out the work without accumulators, and their contract did not include that. It was evident there would be a considerable loss in the mains, and that means for regulating the E.M.F. at their distant end must be provided. This was stated could not be satisfactorily done. In their estimate plaintiffs only specified compound machines, and in answer to the enquiries afterwards sent them they stated they expected to use a $\frac{19}{14}$ main, which would have resistance of about ·68 ohm. The lamp voltage was to be 110, and therefore with such a cable the maximum loss during a night would have been about 20 volts, or 15 per cent., that is, with 50 lights on, which is probably more than required on all ordinary occasions; but if every lamp in the house had been switched on, there would have been a loss of 48 volts, or about 31 per cent. of the dynamo E.M.F. Plaintiffs had not bound themselves to that size of cable, but stated it as the smallest they might use. Their arrangements consisted of a large machine capable of supplying all the lamps to be used during the hours of heavy load, and a small machine capable of driving a little less than half the lamps to be used during the night and hours of light load. Both machines would have been compound wound to raise the E.M.F. as the current increased, so as to compensate for the loss in the cables and maintain a constant E.M.F. at the distant end. That is frequently done with colliery lighting machines, and in other similar places where there is a single pair of mains with the load at the far end. It will be seen that if a cable as small as stated were used the large machine would have to "compound up" nearly 45 per cent. of its minimum E.M.F. (110 volts) when driving every lamp in the house, and it is possible that a machine wound to do this might give an unstable E.M.F., the tendency being always for its E.M.F. to drop too low, if it should be kept running when there was a very light load. This, plaintiffs stated, could be obviated by the use of a Willans governor; it being arranged to operate a switch inserting resistance in the dynamo shunt or the main circuit, thereby correcting and assisting the dynamo regulation as well as increasing its range, the machine being then easily wound within its limits of stability. Plaintiffs stated that they intended to fix an automatic cut-out at the house, so that even if any accident were possible there could be no danger of an injurious E.M.F. reaching the lamps. The cut-out would have, of course, been shunt wound, and adjusted to work at about 115 volts. The small machine had only to compound for two-fifths of the total load, and would in any case be easily made to give a stable E.M.F. and even regulation throughout its range. It will be noticed that the possible failing of the E.M.F. of large machine at light load, even with no governor, would not be any trouble, as the smaller machine only was intended for use during that time. The plaintiffs had also obtained definite offers from Messrs. Crompton and Co., Wilson Hartnell, Esq., of Leeds, and Messrs. A. M. Walker and Co., of Liverpool, all of whom were prepared to supply dynamo machines compound wound for the maximum loss stated, and to guarantee their satisfactorily regulating over the whole range, using a small coupled separate exciter for the shunt and no governor at all. Another method, plaintiffs state, they could have used for the larger machine is that of placing in the circuit a small series wound step-up dynamo to compensate for the loss, it being in series with the large machine, which could then have been plain shunt wound. Their case was simply that they had the contract, and were prepared to prove that they could have carried it out satisfactorily. Although they obtained practically the same terms they had offered before taking proceedings, they state that they much regret having been so interfered with as to obliged them to do so. There being so few places in this country where there is such an excess over the required water power at so convenient a distance, the installation would certainly have been interesting.

On behalf of the plaintiffs the following gentlemen appeared in court to give evidence: Mr. C. T. B. Brain (to whom plaintiffs had previously referred the case), and Messrs. W. H. Pott (representing Messrs. Crompton and Co.), Wilson Hartnell (of Leeds), and A. M. Walker (of Messrs. Walker and Co., Liverpool). Besides Mr. Lester Taylor, the gentleman whom defendant consulted, he had engaged Messrs. A. B. Holmes, F. G. Bailey, T. L. Miller, and W. J. Boult.

COMPANIES' MEETINGS.

LIVERPOOL OVERHEAD RAILWAY COMPANY.

The tenth half-yearly general meeting of the proprietors of this Company was held on Tuesday, at Liverpool, under the presidency of Sir Wm. B. Forwood. The report and statement of accounts were taken as read.

The **Chairman,** in moving their adoption, said: It affords your Directors very great satisfaction to meet you on this the first annual meeting after the completion of our overhead railway. This feeling of satisfaction is very much increased by the fact that the railway, both in its construction and in its electrical equipment, has been most successfully carried out. Very rarely indeed has an undertaking of such magnitude, involving so many considerations of the highest scientific importance, been so successfully inaugurated. From the first week after the railway was opened for public traffic we have maintained a regular and reliable quick service of trains, and to-day, although we are running a five minutes service, 94 per cent. of our trains are on time, and of the remaining 6 per cent. 3 per cent. are irregular only to the extent of a few seconds. Yesterday we ran a 3½ minutes' service without a hitch. For this excellent result we are indebted to the skill of our engineers, Sir Douglas Fox and Mr. Greathead, whom I am glad to see here to-day; last, though by no means least, the attention and care of our general manager and engineer, Mr. Cottrell. Your Directors only modestly claim credit for having insisted upon having first-class work both in the construction and equipment of the railway, and also in having everything thoroughly and carefully tested before opening the line for traffic. The accounts presented to you to-day embrace a period of rather more than 16 weeks; we carried during that period 1,370,742 passengers, or at the rate of 4,300,000 per annum. It is estimated that the penny omnibuses at present running in competition with the railway are carrying at the rate of 2,000,000 passengers per annum, thus making the traffic already developed along the line of docks more than 6,000,000 passengers per annum; and this during a time of great commercial depression, when the shipping trade of the port has been paralysed. This depression has affected the railway in a curious way. Usually the roadway fringing the docks is so blocked with carts and lurries conveying merchandise as to make quick vehicular traffic impossible. At present the goods traffic is so light that the omnibuses have been able to make very fair running time. This, coupled with the extraordinarily fine weather, has no doubt given them a larger proportion of the passengers than will, with ordinary conditions, fall to them. We are every day developing new sources of traffic. A ride upon the electric overhead railway has become an important item in the programme of every well-conducted excursion, and although our present northern terminus is nearly a mile away from the Seaforth shore, we carry large numbers destined for Seaforth. This induces your Directors to expect a large increase of traffic on completion of the northern extension. While we are thus engaged in endeavouring to increase the number of our travellers we are not unmindful of making such economies in our working expenses as may be practicable, having due regard to the efficiency of the service. Electrical traction, combined with automatic electric signals and lighting, should make a very cheaply worked line; and we believe when we take the electrical generating station into our own hands we shall effect a considerable saving. But we have, however, never regretted having placed this part of our system in the hands of the Electric Construction Corporation to work for us until it had been thoroughly tested. You will notice that the result of our 16 weeks' working has been that, after paying all expenses, rates, and taxes, and general charges, there is a balance to the credit of net revenue account of £5,361 15s.; deducting from this interest on debentures and the dividend due on our preference capital, we are left with a balance of £3,293 9s. This is equal to about 2½ per cent. on our ordinary capital for the time we have been at work. Your Directors recommend that the balance be carried forward. The amount of share capital issued is £470,000, and of debenture stock £125,000. This, your Directors estimated, would complete the railway, including the northern expansion to Seaforth, but we find we have to provide about £11,000 to settle the contractor's bill of extras, and a further amount for new stations. We also consider we ought to have a sum in hand as working capital to provide for these items. We, to-day at a special meeting, ask you for power to issue the remainder of the preference capital. We shall, of course, only issue such an amount as may be necessary; we are unable at present to define the

amount, as a good deal depends upon the settlement of our accounts with the Dock Board. These accounts are now in course of adjustment. The northern extension is being proceeded with and should be completed by the end of the year. In conclusion, I have only to repeat what I have said before, that in the overhead railway we have a very valuable property with a sure, and I think rapidly progressive future. There have been many in Liverpool who have been sceptical as to the extent of our traffic, and the estimate we put forward in our prospectus of 5,000,000 passengers per annum was deemed extravagant. We have only been running for four months, yet we see a total traffic developed of over 8,000,000 per annum. It is the old, old story: give rapid, frequent, and cheap means of travel through a populous place, and you cannot fail to create an unlooked for and unexpected amount of travel. These conditions exist upon our railway, and I feel certain you will not be disappointed. No one who has witnessed the marvellous development of local travel which has followed the opening of the overhead railway in New York can doubt that a similar development will take place on the Liverpool Overhead Railway. We are not so fully supported by our merchants and shipowners as we had a right to expect, for the railway was mainly constructed for their convenience and to enable them to economise in their working expenses. Cotton porters, ship people, and passengers still largely use the buses, though the loss of time in doing so is very considerable. I think we may fairly ask the mercantile public to take a little trouble to see that their work-people make use of the railway. We have also introduced cheap workmen's return tickets. Return tickets for 2d. are now issued up to 8 a.m., which are available for return during any hour of the day. We shall consider further concessions in this direction. We see our way to a considerable increase of our excursion traffic next year, and we are every day drawing more and more passengers from those parts of Bootle and Toxteth Park in proximity to the railway. To give you an idea of the earning capacity of the railway—in consequence of the fire at the north end, we yesterday carried 47,456 passengers, our earnings for the day making £413 14s. 3d. The Chairman concluded by moving the adoption of the report and the statement of accounts.

Mr. R. Hobson seconded the motion, which was carried.

On the motion of the **Chairman**, seconded by **Mr. R. Hobson**, a dividend of 5 per cent. per annum upon the preference shares of the Company was declared.

This concluded the business of the ordinary meeting, which then resolved itself into a special meeting.

The **Chairman** said the object had already been explained to them, and he simply moved "That the Directors be and they are hereby authorised to issue 4,500 preference shares of £10 each (being the unissued portion of the 12,000 preference shares of £10 each bearing interest at the rate of £5 per cent. per annum, created by the Company on the 10th day of January, 1893), in such amounts and manner, at such times and on such terms, as they may think fit."

Mr. Hobson seconded, and the resolution was carried unanimously.

Mr. Stevenson, a shareholder, enquired when it was intended to extend the railway southward.

The **Chairman** said they had parliamentary powers to carry the line southward so as to effect a junction with the Cheshire Lines Railway, and if they exercised these powers they would tap a large traffic. They had pledged themselves to the shareholders that they would obtain their sanction before proceeding with the extension, and that pledge they would carry out. At present the Directors thought that it would be better for them to develop the present line before fully undertaking that extension.

Another **Shareholder** asked if it was the intention of the Directors to allot the new issue of preference stock among the ordinary shareholders.

The **Chairman** said the subject would be carefully considered by the Board, and he hoped that the ordinary shareholders would obtain the bulk of the new stock.

A vote of thanks to the Chairman and Directors brought the meeting to a close.

COMPANIES' REPORTS.

BIRMINGHAM CENTRAL TRAMWAYS COMPANY, LIMITED.

Directors: Joseph Ebbsmith, Esq. (chairman), M. J. Smith, Esq., William Neale, Esq., W. J. Carruthers-Wain, Esq., A.I.C.E., managing director.

Report of the Directors to be submitted to the shareholders at the twelfth ordinary general meeting, to be held at the Queen's Hotel, Stephenson place, Birmingham, on Wednesday, August 16, 1893, at 12.30 p.m.

Working Accounts.—Having regard to the malignant and unfounded statements which have been made concerning the affairs of this Company, the Directors trust that every shareholder will give his especial attention to the accounts now presented. The record is one of traffic fully sustained, with a decrease of working expenses and an increase of working profits to the extent shown in the comparative statement.

Revenue Account.—The revenue account shows a balance of £24,216 8s. 1d., to which has to be added the sum of £13,921 18s. 8d. brought forward from last year's accounts, making together £38,138, 6s. 9d.

Appropriation of Profits.—Your Directors recommend (1) that the sum of £20,000 be placed to reserve account against depreciation;

WORKING ACCOUNTS.—COMPARATIVE STATEMENT.

Year ending.	Miles run.	Passengers carried.	Traffic receipts, etc.	Working expenses.	Working profits.
June			£ s. d.	£ s. d.	£ s. d.
30, 1892	2 657,145	25 718 282	152 238 15 2	115,210 13 5	37,028 1 9
30, 1893	2,655,802	26,277,080	154,684 5 8	111,230 4 10	43,454 0 10

(2) that the payment of the dividend upon the 5 per cent. guaranteed shares, amounting to £5,000, be confirmed; (3) that a dividend of 2½ per cent. for the year ending June 30, 1893, be declared and paid upon the ordinary shares of the Company, amounting to £9,700; and (4) that the balance of revenue account, amounting to £3,438. 6s. 9d., be carried forward.

Balance Sheet.—The shareholders will be gratified to observe how completely the audited accounts sustain the reassuring statement made by the chairman of the Board in his circular letter of June 12 in this year. The balance of £9 302. 18s. 4d. due to the bankers on June 30, 1892, has been repaid, and on June 30, 1893, the bankers held the sum of £8,623. 9s. 5d. to the credit of the Company. This result evidences the ignorance, if nothing worse, of those alarmists who wilfully excluded profit-earning power from the resources of the Company. Particular attention is directed to the auditors' certificate. It will be recollected that Mr. Mantle, in his circular of June 2 in this year, stated that the debenture issue could not be increased, and that the reserve fund was non-existent. It will be seen from the auditors' special certificate that the Company have debentures to the amount of £18,000 available for issue, if and when thought advisable; and that the reserve fund is invested in the most legitimate manner in the development of the resources of the Company.

Directors.—Having regard to the special character of the present meeting, the whole of the present ordinary Directors retire; and, being eligible, offer themselves for re-election. They have also the pleasure of stating that Messrs. B. J. Round and J. Booth, both well known citizens of Birmingham and substantial shareholders in this Company, consent to submit themselves as additional directors. The present Directors trust that the nomination of these very representative shareholders may be cordially supported. Mr. Ebbsmith submits himself for election as a director for the ensuing year, upon the representation that his retirement at the present time would be detrimental to the interest of the Company, and upon the condition that he will be permitted to retire from the chair.

Auditors.—Messrs. Howard Smith, Slocombe, and Co., retire, and are eligible for re-election as auditors of the Company.

Note.—Miles run, 140,993; passengers carried, 1,257,399.

The auditors, Messrs. Howard Smith, Slocombe, and Co., chartered accountants, report: "We have examined the books of account, vouchers, and other documents relating to the accounts of the Company, and find the foregoing statements to agree therewith.

We are informed that it is the intention of the Directors to set aside out of the profits of the two years ended June 30, 1892 and 1893, the sum of £20,000 as a reserve against depreciation of assets, and we are of opinion that such provision is sufficient as regards all assets other than leasehold lines and parliamentary concessions, which apparently represent over £300,000 of the capital expenditure, and the present value of which we cannot estimate.

With the foregoing explanation we believe the balance sheet to be a complete and fair statement of the assets and liabilities of the Company, and the revenue and working accounts to truly set forth the transactions of the past year. (*See also special report below.*)

AUDITORS' SPECIAL REPORT.

We have been asked by the Directors to report upon two statements contained in a circular issued by the Birmingham Central Tramways Shareholders' Association, dated June 2, 1893. The first of these statements is as follows: "There is no reserve fund beyond the printed figures which appear in the balance sheet. It is absolutely non existent." In reply to this, we beg to state that in none of the reports and accounts laid before the shareholders has it been suggested that a reserve fund had been invested outside the business of the Company, or that the item "reserve fund" on the debit side of the balance sheet related to any other assets than those shown on the credit side. The reserve fund (£51,126) shown in the balance sheet of June 30, 1892, had been created by transfer thereto of £32,903 premiums on new ordinary shares issued some years ago, less (£11,777) discount on debentures sold, and three sums of £10,000 each charged against the profits of the Company for the years ended June 30, 1889, 1890 and 1891, in accordance with the resolutions passed on the recommendation of the Directors. In our reports on the accounts for those years we stated the reasons why such sums should be set aside, and we further stated that there was a portion of the capital outlay of the Company in respect of which no depreciation had been made. If these three sums of £10,000 each had not been so appropriated, it would have appeared that they were available for dividend. They were, in fact, employed in the business of the Company, and if they had not been so retained and employed, the amount of lost capital to be provided for in any reduction of capital would be increased by £30,000. In the year 1892 a proposal for writing off part of the capital outlay by reduction of share capital was mentioned in the report of the Directors, and for that reason our report on the accounts referred only in general terms to the necessity for a proper addition being made to the reserve against depreciation of assets. The second statement is as follows: "The debenture debt cannot be increased." Upon this we would remark that debentures are issued upon condition that the Company "shall not borrow at any time on mortgage or debenture more than one third of the amount of the subscribed capital of the Company for the time being."

The subscribed capital is	£488,000	0	0
And one third of that amount is	162,666	13	4
The amount borrowed on mortgage or debenture is	144,600	0	0
Therefore the debenture debt can be increased by	£18,066	13	4

BUSINESS NOTES.

Portsmouth.—The chimney shaft at the electric light station in Gunwharf road has been completed. It is 122ft. high.

Southampton.—The docks recently acquired by the South Western Railway Company are to be lighted by electricity.

York.—As will be seen by our advertisement columns, the Technical Instruction Committee of the city of York require tenders for the electric lighting of the institute.

Bournemouth.—The amended estimate of Messrs. Dawson's to erect call bells for £137. 10s., and to maintain them for £17. 10s. per annum, has been accepted by the Town Council.

St. Pancras-Charing Cross Railway.—On Tuesday the Lords' amendments to the Hampstead, St. Pancras and Charing Cross Railway Bill were agreed to by the House of Commons.

Brighton.—The Town Council, as will be seen by our advertisement columns, invite tenders for the supply and erection of fittings for lighting the Municipal School of Science and Art.

Personal.—We understand that Mr. Johnson, secretary and manager of the Sheffield Electric Light and Power Company, sailed for New York by the "Britannia" on the 9th inst. *en route* for Chicago.

Electric Construction Corporation.—Mr. Justice Vaughan Williams has granted a supervision order in the case of the Electric Construction Corporation, the object being to reconstruct the Company.

Newcastle.—The City Lighting Committee have decided to present a report to the Watch Committee requesting them to consider the advisability of acquiring the electric lighting of the city generally.

Power from Refuse.—The experiments which have been in progress at Halifax with a view to bring into practical use a patent for generating power by the burning of refuse are, it is said, likely to lead to the floating of a company.

Liverpool.—In connection with the great fire at Liverpool on Saturday night, the overhead electric railway, running by one of the burnt timber yards, was slightly burnt for a length of about 50ft., but not to such an extent as to interfere with the traffic.

General Electrolytic Patent Company, Limited.—This Company has been registered by W. Bohm, 23, Old Jewry, E.C., with a capital of £24,000 in £1 shares. The object is to enter into an agreement for the acquisition of certain patents, and to develop the same.

Manchester Central Station.—We are informed by Messrs. E. Green and Son, Limited, of 2, Exchange street, Manchester, that they have put down at the central station a large economiser in connection with the boiler plant, and that it will result in a great saving in fuel.

City and South London Railway Company.—The receipts for the week ending August 6 were £801, against £919 for the same period last year, or a decrease of £118. The total receipts for the second half year of 1893 show an increase of £286 over those for the corresponding period of 1892.

Ambleside.—At the monthly meeting of the Local Board a letter was read from the Holloway Electric Company, and also from Messrs. Fell and Son, of Troutbeck Bridge, respecting the laying of electric wires. The Holloway Company were going to apply for a provisional order to supply the Ambleside Local Board.

Derby.—A general trades and industrial exhibition is being held at Derby. The exhibits, which belong mostly to local firms, are classed under four general heads—namely, engineering, electrical, inventions, and manufactures. There are altogether 106 exhibitors, 76 of whom are local tradespeople and manufacturers. The most prominent feature of the exhibition is, perhaps, the electrical machinery.

Salt Lake City.—The Gas, Water, and General Investment Trust are offering for subscription 1,250,000dol. 6 per cent. first mortgage bonds at the price of £205 per 1,000dol., secured by a registered first mortgage over the properties of the Salt Lake and Ogden Gas and Electric Light Company, subject only to outstanding bond issues, amounting in all to 110,000dol., which will be paid or provided for out of the present issue.

Burnley.—Supplementing our remarks of last week concerning the condition of electric lighting, Alderman Lancaster, at the meeting of the Town Council, said that as soon as the plant was completed the committee proposed to have an exhibition of electrical apparatus, lamps, switches, etc., and to throw it open as far as possible to the public, so that they could go and inspect the station, and see what could be done with the electric light.

Agency.—Mr. L. H. Bloomfield, of 11, Queen Victoria street, E.C., informs us that he has taken over the sole representation in the United Kingdom of Messrs. O. L. Kummer and Co., electrical engineers, of Dresden. Mr. Bloomfield will undertake the laying down of plant of every description. Messrs. Kummer and Co. are large makers of accessories for electric lighting, as, for instance, carbons, insulators, lampholders, switchboards, volt and ammeters, accumulators, portable batteries, etc.

West Bromwich.—At a meeting last week of the Town Council, the Highway Committee reported that they had received a communication from the Board of Trade granting an extension of the time for the use of steam on the South Staffordshire tramways till April 1st next, upon the understanding that the company will promote an order in the next session of Parliament to substitute some other motive power for steam, in which case there is to be a further extension for nine months to enable the works to be carried out.

Chesterfield.—On Tuesday, Alderman Wood, at the quarterly meeting of the Town Council, in moving the adoption of the minutes of the Electric Lighting Committee, said the Council would see from the report of the engineer that until a circular had been sent out to those residing within what the engineer termed the trade area, and replies were received saying how many lamps they would take, they could not proceed much further. When replies were received figures would be laid before the Council. The minutes were adopted.

Wakefield.—At a meeting last week of the City Council, the minutes of the Sanitary Committee contained the following: "The report of the Electric Lighting Sub-Committee, laid before the last meeting with respect to the visit made by them to Leeds on the 21st ultimo, when they inspected the lighting station of the Leeds Electric Supply Company, Limited, and the works of Messrs. John Fowler and Co., Limited, was again read, and the town clerk was directed to write Mr. Hammond, of London, and make an appointment with him to meet the committee on the 26th inst."

Canterbury.—The Electric Lighting Committee of the Town Council recommended last week the approval of the transfer of the Canterbury Electric Lighting Order, 1891, as amended by the Board of Trade. The Mayor said the committee found that the slight alterations made by the Board of Trade in the electric lighting order were rather in favour of the company than the Corporation, showing that the city representatives had exacted quite as much as was due to them. They had accepted the alteration in the agreement and were only awaiting the confirmation of the Dover people.

The Strand.—The Strand District Board of Works have had under consideration the electric lighting of the Strand by the Metropolitan Electric Light Company, who proposed to substitute for the present 67 gas lamps, costing £473. 11s. 11d. per annum,

22 arc lamps at a yearly cost, including renewals of carbons, cleaning, and all attendance, of £1,195 per annum, on the assumption that half that number of lamps would be extinguished at midnight. As, however, the increase in cost over the present system of lighting by gas would be more than 100 per cent., the Board decided not to adopt the electric light until it became cheaper.

Keighley. The subject of electric lighting was discussed by the Town Council on Tuesday on the occasion of the recommendation of the Gas Committee to apply for borrowing powers to the extent of £30,000 for gasworks extension purposes. It was urged that the committee should take steps towards furnishing a supply of electric light, but Alderman Brigg said they were carefully watching experiments, and it might be possible to find some system cheaper and better than that in use in many places. But however that might be, it was generally found that the adoption of electric lighting did not diminish, but rather increased, the consumption of gas. The recommendation was adopted.

Eccles. The electric lighting order promoted by the Town Council has received the Royal assent, and copies of the order have been furnished to members of the Borough Council. The second schedule to the order provides that within two years sufficient and suitable mains shall be laid to light various streets. The first schedule states that the area of supply shall be the whole of the borough of Eccles, and in addition to the mains specified the Corporation shall at any time after the expiration of 18 months after the commencement of the order lay down suitable and sufficient mains for general supply through every street of the borough upon being required to do so in the manner provided by the order.

Aberdeen. The Gas Committee of the Town Council have recommended the Council to fix the price for the supply of electricity to private consumers at 7d. per Board of Trade unit. The Gas Committee, at a meeting of the Town Council on Monday, submitted a list of candidates for the appointment of electrical engineer, and stated that one of the applicants, Mr. A. H. Gibbings, Sussex, had withdrawn, having received an appointment in Hull. A vote was taken between the other three candidates—viz., Mr. J. Christie, Glasgow; Mr. E. T. Ruthven Murray, Larne, co. Antrim; and Mr. A. C. Nixon, Belgravia, London. On a division, Mr. Murray was declared to be elected, the remuneration being £200 per annum.

Rugby School Electric Lighting Company.—Under this title a company has been registered to supply electricity to the boarding houses and to the buildings of or connected with the school, and all buildings occupied by persons residing in Rugby holding appointments in the school or in connection therewith. The nominal capital is £5,500, divided into 110 shares of £50 each. The registered address is Dunchurch road, Rugby. The subscribers to the articles of association are: J. Percival, J. Collins, F. D. Morice, A. E. Donkin, W. Gordon Michell, W. Parker Brooke, G. Stallard, C. Godfrey Steel, and R. Whitelaw. At present it is only intended to supply the schools and boarding houses. The necessary buildings are being erected, and most of the plant is said to have arrived.

Fareham. At a meeting of the Local Board, the question of the contract with the electric lighting company for supplying light for the streets came on for consideration. The clerk read the contract as amended since the last meeting and it was pointed out that the only difference was that the lights were now described, and that the penalties for inefficient lighting were reduced from 3d. to 1½d. per hour for arc lights, and ½d. per hour for incandescent lamps. The company agreed to give the same number of lights—20 arc lamps of 1,200 nominal candle power each, and 92 incandescent lamps of 20 nominal candle power each, for the sum of £549 per annum for a period of three years, the contract to be terminable by six months' notice if the light did not reach the proper standard. After a discussion, it was resolved that the contract be sealed with the company.

Rochdale Sanitary Works. The sanitary works of the Corporation have been electrically equipped by Messrs. Laing, Wharton, and Down, and the switching on of the light took place on the 4th inst. There are about 80 lights of various powers—ranging from 16 candles to 50—and they illuminate the whole of the works, stables, offices, yard, etc. The lamps are arranged so as to suit their varied positions. A slow-speed incandescent light dynamo is worked by the waste power of the engine which drives the machinery, so that there is practically no extra cost for motive power. The engine is equal to about 100 h.p., and since the stoppage of the pulsometer at the sewage works it is quite capable of doing more work than it does now. The boiler fuel consists entirely of rubbish, no coal being used. The arrangements are made so that the number of lights could easily be doubled if necessary. The Health Committee of the Corporation met to start the lighting, and Councillor Hardman said these were the only sanitary works in the world in which the electric light was in use. He also remarked on the fact that the driving power was obtained from refuse which in other towns was thrown away and wasted. The Health Committee were to be congratulated on their economical and progressive policy.

Stafford.—Last week, at a quarterly meeting of the Town Council, the Electric Lighting Committee recommended the carrying out of the scheme proposed by Mr. Bell, gas engineer, and endorsed by Dr. John Hopkinson, and that application be made to the Local Government Board for authority to borrow £20,000 for the erection of buildings and an electrical installation, £12,000 of which was to be spent at once. Alderman W. H. Peach (chairman of the committee) proposed the adoption of the report. Dr. Hopkinson did not suggest any street electric lighting at present, but only to supply private consumers. He gave it as his opinion that they could supply the electric light at a small profit with 15,000 to 20,000 lamps. Mr. Peach pointed out that they had got customers who would have 15,000 lamps at the price of 7d. per unit, which was the price which the committee proposed to charge. The system recommended was the continuous current low tension one. This was thought to be the best for Stafford, as it lent itself most readily to extension when required. Councillor Wormal seconded, and after some discussion the report of the committee was carried. On the recommendation of the Gas Committee, it was resolved that sufficient land be set apart at the gasworks for a site for the electric supply station, and that Mr. Bell be requested to prepare plans, etc., for the necessary works.

Bolton.—A central station is to be erected in Spa road, and tenders are now being obtained by the architects, Messrs. Hinnell and Murphy. The station is to be erected on land belonging to the Gas Committee, the offices having a frontage to Spa road, and the engine and dynamo house, boiler house, chimneys, sheds, etc., being erected at the rear. The office buildings will be two storeys in height, the ground floor comprising enquiry, drawing, and engineers' office, with lavatory and other accommodation. The first floor will contain committee room, testing and accumulator room, and also a passage from which admittance is gained to the switchboard gallery. The offices are to be built with brick, faced with stone, the floors are to be of concrete and wood blocks, and the roof, which is of timber, is to be ventilated by means of tube inlets and flue outlets. The works buildings will consist of boiler house, 83ft. 6in. by 50ft., for accommodating six boilers, the requisite coal shoots, bunkers, and concrete water tanks; also circular chimney, 50 yards high, engine and dynamo house, repairing shop and storeroom, closed shed for stores, open shed in yard for carts, tools, etc., and railway siding. The engine and dynamo house and boiler house are to be built of brick, the floors being of concrete, and the roofs of wrought iron, that of the boiler house being louvred. The chimney is to be built of brick with stone capping, and provided with lightning conductor. The flues are arranged so that any number and any of the boilers may be worked at the same time. The engine and dynamo house will be provided with machinery entrance, iron ladder to switchboard gallery, with suitable foundations of concrete and stone.

Richmond Electric Lighting.—At the Richmond Town Council last week the Electric Lighting Committee reported as follows: "The committee have been in communication with Latimer Clark and Co. on the subject of the lighting of the public street between the Kew road railway bridge and the bridge over the river, and the matter is now referred to Messrs. Urquhart and Small, the newly-appointed electrical engineers to the Corporation, for consideration and report. The feeding mains for the electric light have been laid in Eton-street, and the distributing mains are now being laid on one side of George-street, leaving the other side to be done when the fire call cables are ready to be laid, thus avoiding the reopening of the pavement trenches. Mr. Shoolbred has declined the offer of the Council to pay him £105 in respect of his charges against the Corporation, and the matter having been placed in his solicitor's hands, is left with the town clerk, who has received a communication from the solicitor, and the committee will be able to report further hereon hereafter. Meanwhile the clerk was instructed to ask for all plans and papers in Mr. Shoolbred's possession, which have been obtained." Councillor Christie urged the need of watching the manner of the erection of the electric lighting works now in progress, with a view to what the Council might have to pay for them when eventually taking them over. The Mayor said that at the end of 30 years the Corporation would take over the works at a valuation, and not upon the basis of what they cost. Councillor Ryan had a notice upon the paper, to move "That the reports of and correspondence with Mr. Shoolbred, C.E., and the Electric Lighting Committee, be printed." He consented to adjourn his motion, as the Council had been sitting for more than four hours.

Fire Alarms at Richmond. The Richmond Town Council have decided to have a system of fire alarms instituted throughout the borough, and at the monthly meeting last week the Works Committee presented a supplementary report on tenders for electrical apparatus as follows: "Electric Fire Calls.—The committee have received a number of tenders for these works, the list of which will be laid on the table at the Council meeting. They recommend the Council to accept the tender of Messrs. Blinko and Co., of 34, Leadenhall street, £899. 10s. (the lowest tender), for cables, wires, boxes, etc., and their tender at £153. 10s. for instruments and apparatus, together £1,053, subject to the sureties being satisfactory, and that the contract be sealed. The committee also recommend that they be allowed to have the work carried out forthwith." The Mayor said that since the report was presented it had been thought that it might be better to accept the tender of Messrs. Callender and Co., £980. 19s. 6d., in preference, for the cables, as they were the makers, and this might ensure more prompt delivery. He moved that that tender should be accepted, and that the question of the tender for instruments should for the present be left over. Councillor Ryan thought the Council would be acting wisely in adopting this amendment. The question of time was very important, and he did not think that it would be well to give the contract simply to the lowest tenderer. He also thought that no tender for instruments should be accepted before the most careful enquiry had been made with regard to the ability of the firm to fill it. The Mayor's recommendation was adopted. Councillor Bickerton enquired what limit of time there was during

which the company would be bound to make good the roads and footpaths disturbed. The Mayor said the surveyor made good the places disturbed at the expense of the contractors.

Cheltenham. -The report of the Electric Lighting Committee of the Town Council, presented on Tuesday by Mr. George Norman (chairman of the committee), recommended the adoption of the high pressure alternating-current system for the town, the supply to be undertaken by the Corporation, using the ash destructor site for the station. Mr Norman explained that Mr. W. H. Preece had given the committee the benefit of his advice. In the course of his interview with the committee, Mr. Preece said he had the strongest belief that the only satisfactory system which they could introduce, and which would give proper financial results, was the high pressure system. The low pressure system would mean that they would require a central station in a central part of the town, and that they would have to expend a large sum of money in mains. The high pressure system meant that they could place their station anywhere, and that they would not have to spend so much money in mains The ash-destructor station was eminently adapted for a central station, as the destructor would always be at work, and this was an element of considerable economy in the working expenses. He had no doubt as to the success of the light. He would not go so far as to say that in the first year they would make sufficient to pay interest on redemption fund, but they would cover their working expenses; and in the second year there was not the slightest question they would clear sufficient to pay interest and provide a sinking fund as well. Dealing with the question of cost, Mr. Preece said "Gas at 3s. per 1,000 is equivalent to electricity at 6d. per unit. Therefore if you introduce your electricity as you propose, at 6d. per unit, you are introducing a light which is equivalent to gas at 3s. per 1,000ft. If you get a large *clientèle* and have also a long use for the light your cost would come to less than 4d per unit, and you would be in a position to reduce the charge to perhaps even less than 3d. per unit." Mr Norman having moved the adoption of the committee's recommendation, Alderman Colonel Moyts seconded the motion, which was adopted.

Gas and Electric Lighting in Glasgow. -The report by the Committee of Gas Supply and Electric Lighting for the year ending May 31 has been issued. The gross revenue of the gas department for the year amounts to £594,049, and the gross expenditure to £464,449, to which is added depreciation, written off capital, £34 419, leaving a balance of £95,181 to be carried to profit and loss account. After meeting payments for annuities on stock, interest on borrowed money, and sinking fund, there remains a surplus on the year's operations of £29,539 Out of this sum the committee have met the balance at the debit of previous year's accounts of £26,139, the loss on the electric lighting account of £1,773, and have transferred to insurance fund £1,500, leaving a balance of £126. In the electric lighting department the gross revenue from March 1, 1892, to May 31, 1893, amounted to £7,784, and the gross expenditure to £5 416, to which was added depreciation written off capital, £1,328, leaving a balance of £1,039 The committee had to meet interest on loans, £2,012 18s 10d., payment to sinking fund, £800; and, deducting these sums from the credit balance, there remained a deficiency of £1,173, which was transferred to the debit of the gas account. The above result was not unexpected by the committee during the first year's operations. The capital expenditure on the new system during the greater part of the year was unproductive of revenue, and in the meantime interest had to be paid upon the money borrowed. The committee fixed the price of electric energy from June 1, 1892, at 7d per Board of Trade unit, at which price they recommend it should be continued for the current year. During the period of this account the committee had purchased ground at the corner of Waterloo and Mains streets, and have erected thereon a central supply station, which, with machinery and plant, has cost £44,000. The committee were glad to state that not only will these works be fully employed during the winter, but that it had already been found necessary to extend the plant in order to meet the increasing demand for current, and they hope that the future reports of this enterprise will show an increasing prosperity from year to year. The number of consumers when the undertaking was acquired by the Corporation was 37, while the number at May 31, 1893, had increased to 108.

Glasgow.—The question of the municipalisation of telephones came up for discussion at the quarterly meeting of the Town Council on the 3rd inst Mr. Starke, in moving the approval of the minutes of the Telephone Committee, and of the relative minute of the Finance Committee, said the committee had resolved to recommend that an application be made to the Postmaster General, in terms of the Treasury minute of May 23, 1892, for a license to supply the community with an efficient telephone service A deputation of the Telephone Committee afterwards met with the Finance Committee for the purpose of seeing as to ways and means by which the proposal might be carried out. The Finance Committee heard their statement, and gave it a hearty and generous response, and "resolved to concur in the recommendation of the special committee that an application should be made for a license They further agreed to recommend that the Corporation should advance the sum necessary to start the system, but that, after the license is obtained, the first opportunity should be taken to apply to Parliament for statutory powers" There was a general feeling that this matter must be taken up by the State or by the municipal authorities in connection with the State. Having explained the position of the Government in the matter and that they had erected two great trunk lines between London and Glasgow and one between London and Edinburgh, with branch lines from them to the large English cities, Mr. Starke contended that it lay with municipalities to provide an adequate local service. It was becoming, he said, that Glasgow, among all the great corporations, with the prestige she held as a bold and successful exponent of municipal enterprise, should step out and be the first in the direction of dealing with the telephone service. There were other cities watching very carefully what they did that day, and which might follow in their footsteps. The system in Glasgow, which was a single wire system, was totally unfitted for such a great city. On the financial aspect of the question, Mr. Starke said that so far as they could get reliable estimates they could lay down a new system in Glasgow for 3,500 users for £52,000. As to the financial arrangements, he pointed out that 3,500 subscribers at £5 per head would amount to £17,500, and there would be at least 2,000 private instruments, which would make the income £19,500. The working expenses might be reasonably taken to mean 50 per cent. of the revenue, while the Government license would be 10 per cent. on the net income. Then he proposed that 5 per cent. should be set aside every year as a sinking fund, so that the whole should be wiped out in 20 years. He thought they were entitled to take from that the interest which would accrue on the subscriptions paid in advance. Allowing £2,000 for sundries, he estimated they would have a clear revenue of between £5,000 and £6,000 per annum. Bailie Alexander seconded the motion. Bailie Primrose moved that the whole subject be remitted to a committee for further consideration, with instruction to report fully and in detail. After further discussion, the motion as amended was adopted.

Hampstead. The results of tenders will be found in our last issue, but it may be useful to be able to compare the amounts, so we give the report of the committee on the subject "1. For the erection of a chimney shaft and buildings for the proposed central electric supply station, with foundations for the machinery, etc. 2. For the plant for the proposed station and the provision of the necessary mains, etc., in the compulsory area. Your committee beg to state (1) That the following is a list of the tenders received in response to the advertisements issued—viz.: (a) For the buildings (including chimney shaft), 12 tenders:

Yerbury and Sons	£10,870
Killby and Gayford	10,634
Holliday and Greenwood	10,555
Simmons Bros	10,300
Reid, Blight, and Co.	10 300
Chessum and Sons	10,185
Neil	10,000
Wall Bros	9,825
McCormick and Sons	9,700
Ballard	9,477
Allen and Son	9,339
Allen and Son	9,189

(b) For the plant—31 tenders, of which number six only were from firms tendering for the whole of the sections included in the specifications—viz.:

Brush Company	£22,047
Latimer Clark and Co.	21,850
Latimer Clark and Co. (alternative tender)	21,129
Sharp and Kent	21,572
Crompton and Co.	21,512
Electric Construction Corporation	21,232
Siemens Bros and Co.	19,914
Siemens Bros. and Co. (alternative tender)	19,120

(2) As to the buildings: The prices being much in excess of the estimate, your committee appointed a sub-committee to examine, in conjunction with Mr. Preece and the architect, the drawings and specifications with a view to see whether, with a due regard to efficient work, any saving in expense could be secured in constructing the buildings and shaft. The result of this examination was that certain modifications were determined upon, the plans and specifications were revised, and the parties tendering also revised their estimates in accordance therewith, the same now being as follows:

Wall Bros.	£8,425
Reid, Blight, and Co.	8,295
Killby and Gayford	8,270
Neil	8,092
Holliday and Greenwood	7,836
McCormick and Sons	7,794
Simmons Bros.	7,536
Yerbury and Sons	7,350
Chessum and Sons	7,344
Ballard	7,207
Allen and Son	7,100

After careful consideration your committee have determined to recommend that the tender of Messrs. R. A. Yerbury and Sons, of Birchington road, Kilburn, for the erection of the chimney-shaft and buildings for the proposed central electric supply station at the parish stoneyard, Lithos road, with foundations for the machinery, etc., in conformity with the specifications and plans prepared by Mr Preece, for the sum of £7,350 be accepted. The original estimate for the buildings was £6,000, but the committee considered it advisable to build at once a chimney shaft large enough to accommodate the machinery required for lighting the whole parish, and so to arrange the building as to hold one extra boiler, and to be easily adapted for extensions. The larger shaft was estimated to cost at least £1,000 extra. It will, therefore, be seen that the actual tender recommended for acceptance is only £350 above the estimate. (3) As to the plant:

A long report on these tenders was presented by Mr. Preece, who pointed out that he had found it advisable, in view of future requirements, to add an extra boiler, and also to increase the size of one of the steam dynamos. These alterations entailed an extra cost of about £1,000 After carefully considering the question of efficiency of the machinery proposed, and the experience in the type of machinery required, your committee resolved to recommend that the tender of Messrs. Siemens Bros and Co., of 12, Queen Anne's gate, Westminster, for the supply of electric lighting plant, for proposed installation at the parish stoneyard, together with the necessary mains, etc., for the compulsory area in conformity with the specifications and plans prepared by Mr. Preece, for the sum of £19,794, be accepted Note. This sum of £19,794 represents Messrs. Siemens's tender of £19,914, subject to a deduction of £120." As we stated, the tenders of Messrs Yerbury and Sons for building and of Messrs. Siemens for plant were accepted, and the Electric Lighting Committee is now left to carry out the work.

Peterborough. -A public meeting was held last week at the Angel Hotel, under the presidency of the Mayor, to consider the question of electric lighting The Mayor, in introducing Mr. Hammond, said there were some difficulties at present existing in the minds of the Corporation as to whether the time had arrived when they should take up this subject. Hitherto Peterborough had been pretty well to the fore in railways and many other things, and he did not think they would allow the town to be backward in the matter of electric lighting Mr Hammond then gave an explanation of how the electric light was generated, and the manner in which it was distributed He claimed for the light a great superiority over other artificial illuminants, one most important feature being the fact that it did not feed upon the air, as was the case with gas or lamps, which robbed the atmosphere in a room of its life-sustaining properties. Another great advantage of the electric incandescent lamp was its absolute freedom from danger or fire, it being quite impossible to light anything from an incandescent lamp because immediately the glass containing the light was broken the light went out The electric light did no damage to ceilings and furniture. Recent improvements insisted on by the Board of Trade had made electric lighting free from the possibilities of serious accidents, the pressure required to light an incandescent lamp being so small that should a person touch the wires so as to bring them into contact, there would be no danger whatever. The electric light was so convenient to turn off and on, no matches being required, that a great difference was thereby saved in the cost. Dealing with the cost, Mr Hammond said some people were inclined to wait before going in for electric lighting, under the impression that there would would be a marked reduction in the cost in a few years, but this he said was a mistaken notion, for as far as apparatus was concerned, they had got very nearly to the lowest level There was every reason to gather from Board of Trade returns that electricity could be produced and distributed at a profit at 6d per unit, which was equivalent to gas at 3s and 3s 4d per 1,000 cubic feet. Some of the companies were making a profit at 4d per unit, but 6d. would equal the price paid in Peterborough for gas The present Act under which electric lighting was carried out was very strict, and there was not a single instance of a system laid down under this Act that had not been a success, and there was not a single house to house supply system that had proved a failure Electrical works at present in operation had absorbed four and a half millions of capital, of which amount four millions was provided by the companies, and half a million by local authorities, but if they considered works at present in hand and others for which sanction had been obtained, they found the capital provided by companies had only increased to £4,188,000, whilst that of local authorities had risen to £2,000,000 The electric lighting business at the present time could be shown to be on a sound basis, and some towns which had allowed private companies to step in and supply the light were already talking of buying the companies out. The cheapening of the incandescent lamp made him confident that in a very short time they would be able to supply electricity at a cheaper price than gas, to say nothing of its other innumerable advantages In reply to Councillor Nichols, Mr. Hammond said he should say they could make a very profitable beginning in Peterborough with a capital of £9,000 or £10,000 At the close of the proceedings it was decided to memorialise the Town Council to either adopt the electric light or allow a private company to step in.

PROVISIONAL PATENTS, 1893.

JULY 31.

14640. **A form of water actuated electric switch.** Alfred René Upward, 150, Holland road Kensington, London.

14643. **Beboutoff's automatical and electrical pile or monkey driver.** Prince Abessalum Beboutoff, Fincastle House, Queen's terrace, Middlesbrough

14647. **Improvements in apparatus for working electric tramways by means of underground cables.** Christopher Anderson, Lane House, Jack lane, Hunslet, Leeds

14664. **Improvements in electromotors for alternating currents.** John Augustine Kingdon, 29, Marlborough hill, St. John's Wood, London

14685. **Improvements in and relating to apparatus for heating and warming by electricity.** Lionel Herbert Hordern, 70, Chancery-lane, London.

AUGUST 1.

14715 **Improved bell-pull arrangement for electric bells.** Edgar Godwin Harcourt, 13, Temple street, Birmingham.

14742. **Improvements in or appertaining to electric light fittings.** Frederick William Plumstead and Henry Hatt Hunter, 121, Chancery lane, London

14756. **Improvements in dynamo-electric generators and motors.** Alfred George Brookes 55, Chancery lane, London. (Harris Joseph Ryan.) Complete specification.

AUGUST 2.

14816. **An improved electromotor for boats and like purposes.** Albert Antoine Lateulère, 97, Newgate street, London.

AUGUST 3.

14863. **Improvements in electrical resistances.** Albert Campbell, Ballynagard House, Londonderry.

14868. **Improvements in electricity meters.** John Thomson, 87, St Vincent street, Glasgow.

14910 **A method of and apparatus for electrolytical decomposition while using quicksilver as cathode** Peter Jensen, 77, Chancery lane, London. (Alf Sinding-Larsen, Norway.) (Complete specification.)

AUGUST 4.

14953. **Improvements in regulating the supply of electricity to incandescent lamps** Thomas Budworth Sharp, County chambers, Martineau street, Birmingham.

14966. **Improvements in the construction of loud-speaking micro telephones.** Edward Morway, 27, Chancery-lane, London.

14969. **Improvements relating to two-pole dynamos motors, and the like** Francis Murray Newton and Tom Hawkins, Norfolk House, Norfolk street, London.

14979. **Improvements in electric lighting and signalling apparatus for use on cycles and other vehicles** Alfred Julius Boult, 323, High Holborn, London. (Carl Duvivier, Belgium.)

14997. **Improvements in electric contacts for telegraphic vibrators.** Edmund Edwards, 35, Southampton buildings Chancery lane, London. (Paul la Cour, Denmark)

15001. **Improvements in telegraph forms** Cyril Arthur Pearson and Frederick Jonathan Gallaher, 37, Chancery lane, London.

AUGUST 5.

15025. **An electric plant protector.** Francis Alexander James FitzGerald, 27, Upper Merrion street, Dublin

15050. **Slow striking electric bells.** Hermann Oppenheimer, 55, Redcross street, London.

15064 **An improved electric arc lamp** Frank West Suter and Sydney John Suter, 28, Southampton buildings Chancery-lane London

15073 **Improvements in electric arc lamps.** Henry Hayes Cooper and the Electrical Installation Company, Limited, 53, Chancery lane, London

15074. **An improved electric coupling.** Henry Hayes Cooper and the Electrical Installation Company, Limited, 53, Chancery lane, London

SPECIFICATIONS PUBLISHED

1892.

13395. **Electrical signalling.** Mercier.

13543. **Electrical installations** Siemens Bros and Co., Limited. (Siemens and Halske

16046 **Electrolytic decomposition of alkaline salts.** Castner.

16489. **Electrical rock drill.** Taylor

17691. **Cutting glass by electricity.** Havaux

1893.

10347. **Battery switches.** Spangenberg

11143. **Electrical switches, etc.** Dorman and Smith

11622. **Magnetic separation.** Sanders and Thompson

NOTES.

Verdun.—The local gas company is lighting the Grand Theatre by electricity.

Bilbao.—The electric light has been installed in the telegraph station at Bilbao.

Bournemouth.—The new Hotel Metropole, opened on Tuesday, is lighted electrically.

Bernburg.—Electricity works are shortly to be erected here for lighting purposes, and for the working of an electric tramway.

Motte-Chalencon.—The electric light installation in this town has been experimentally run, and lighting is now being commenced.

Bournemouth.—We understand that a station for the charging of carriage, police, cycle, and portable lamps is to be opened in a few weeks.

Metz.—The military hospital is to be lighted by electricity; the motive power to be obtained from the fall of water at the Sauley Island.

Grasse.—The subject of connecting Grasse with the railway station by means of an electric tramway two miles long is under consideration.

The Azores.—The steamer "Seine," which has been chartered to lay the new cable between Portugal and the Azores, left Lisbon on Sunday.

Whitworth Scholarship.—A scholarship worth £125 a year, tenable for three years, has been gained by Mr. W. Hamilton, electrical engineer, of Glasgow.

Induction.—The working of the electric tramway started between Herstel and Wandre, Belgium, a short time ago, has caused disturbances in the telephone wires carried alongside the line.

Oil Insulation.—We are glad to learn that the oil-insulated system of underground mains is working satisfactorily. The mains can now be laid for the transmission of current at any voltage.

Franco Swiss Telephony.—The conditions under which telephonic communication is to be carried on between France and Switzerland have been published by the Government of the former country.

Villa Borghese.—An electric tramway just over one mile in length has been put in operation to connect the Porte Pinciano and the Villa Borghèse. There are three cars in service on the storage battery system.

Hamburg.—The preparations for the working of the tramways by electric power have been well advanced by the Union Electricity Company, and the belt line is proposed to be set in operation in November.

Paris.—The formation of a new company is spoken of in Paris for the electrical transmission of power over long distances. For this purpose it is intended to utilise water power in the midlands and south east of France.

Underground Conduits.—The large orders mentioned in another column as having been obtained for the Johnstone system of underground conduits show that this system has obtained a firm footing in this country.

Commerce.—The furtherance of technical education and the adoption of the decimal system will be considered at the autumn meeting on September 26 and 27, to be held at Plymouth, of the Associated Chambers of Commerce

Miners and Electricity.—The members of the society frequenting the Bergmannstag at the meeting at Klagenfurth, Austria, on Wednesday and yesterday, are considering, among other matters, the subject of electricity in mining.

Obituary.—The death has just occurred at Canonbury of Mr. W. S. B. Woolhouse, F.R.A.S., who was a well-known mathematician. He contributed to the *Philosophical Magazine* for May, 1860, a paper on "The Deposit of Submarine Cables."

Milan.—Operations have already been commenced at Milan by the Edison Company on the work of constructing the electric tramway on the overhead trolley system. The generating station contains steam-engines, driving two dynamos of 150 h.p. each.

Transmission of Power.—A concession has been asked for by a Frankfort company for the utilisation of the water power of the Lech, near Gersthofen. The available water power amounts to 5,000 h.p., and it is proposed to transmit this to Augsburg and the neighbourhood.

Gas, Electricity, and Water.—In Rhineland and Westphalia these subjects are treated at meetings of a society constituted to consider the three interests, and usually information of much value is adduced. At the general meeting, however, just held, nothing of importance as regards electricity or gas was brought forward.

South London Railway.—The bursting of a water-main at the Oval Station of the City and South London Railway on Tuesday evening caused considerable inconvenience. The main conveys water for operating the hydraulic lifts. Before the supply could be turned off the water partially flooded the line, and it was with great difficulty that trains could proceed.

Simultaneous Contrast Colours.—The very interesting article by Mr. Alfred M. Mayer on "Simultaneous Contrast Colours, and a New Photometer for Measuring Lights of Different Colours," which we recently mentioned, is given in the *Philosophical Magazine* for this month. It is certainly worth reading in full by those interested in photometrical studies.

The Remscheid Tramway.—The popularity of this electric tramway is shown by the fact that during the first four weeks that the line has been at work, no less than 65,674 passengers have been carried. A third generating set—boiler, engine, and dynamo—is to be laid down and five new cars put into service. This is good progress considering that the tramway was started only at the beginning of July.

Electrical Purification of Sewage.—Some interesting experiments in this direction are being carried out in the most populous and unhealthy part of Havre, and they concern the destruction of the impure elements in both liquid and solid sewage. Hopes are entertained that the results of the experiments will facilitate a solution of the problem relating to the drainage of Havre, upon which the municipality is about to spend £400,000.

Switches.—A revised price-list of fittings has been issued by Mr. A. P. Lundberg, of Bradbury street, Kingsland, N. One of the chief specialities made is the "Unique" switch, which we described some time ago, and the popularity of which is shown by the fact that since its introduction last year nearly 30,000 have been disposed of. Illustrated descriptions are given of the "Unique" main and other switches, sockets, ceiling roses, etc.

Electricity in Mining.—An important installation has been carried out at the Ziegler pit of the Blattnitz steam-coal mines at Nurschan, near Pilsen. On the surface is arranged a steam-engine of 120 h.p., which drives a continuous-current dynamo used for lighting the under-

ground roads. Here the current is employed to actuate various motors which operate hauling engines, ventilators, pumps, and a chain tramway. It is shortly intended to increase the plant and lay down two rock-drills.

Price of Gas.—The members of the Gas Consumers' Protection League, recently formed to obtain a reduction in the price of gas supplied by the Gaslight and Coke Company, and generally to protect the interests of gas consumers north of the Thames, met on Wednesday at the Foresters' Hall, Clerkenwell-road. The members would do well to support an electric light scheme, and although they may have to pay more for the light, they would not grumble about that, because of its superior advantages over gas illumination.

Crystal Palace School of Engineering.—On Saturday the thirty-third session was terminated, and the successful students received their first-class certificates. The examiners' report specially dwelt on the importance of the electrical section. The following were the most successful students: H. A. Bailey, W. Collins, G. Stirling, R. H. Pocklington, P. H. J. Bishop, W. C. Gravely, T. A. S. Dyer, D. Clark, J. Braby, H. T. Cressy, R. H. Hayne, F. H. Hodson, J. C. Lyell, R. F. Skinner, H. F. Deslandes, A. D. O. Travers, and M. G. Bradford.

Birmingham Electric Cars.—The proceedings at the annual meeting of the Birmingham Central Tramways Company on Wednesday were of an animated character. As the chairman mentioned, the conclusions of the Joint Parliamentary Committee on Electric Traction Powers had removed the restrictions which the telephone company had sought to place upon them. The company had been encouraged to proceed with negotiations which had been held in suspense, and which they believed would mean a profit to the company upon the Bristol-road line of not less than £2,000 per annum.

Richmond.—A correspondent complains of the erection by the electric light company of a high chimney in the centre of Richmond, and which he regards as an eyesore. He states that: "It may be urged, perhaps, that the lower part of the town is unpicturesque and commercial, and therefore that the interests and the feelings of the inhabitants are unworthy of consideration; but when this monster chimney is completed the dwellers on the hill will find that they too have their part in the nuisance, and that, intersecting the fine northward view and the wooded valley of Kew and Isleworth, there will stand a hideous shaft more suggestive of Oldham or Warrington than of a favourite West-end suburb."

Electric Cautery.—This subject was referred to in the evidence given before the Select Committee on the Marking of Foreign Meat. In their report, issued on Monday, the committee state that they are disposed to believe that after public attention has been called to the system of marking by electric cautery, the improvements of inventors and the experiments of agricultural societies and other bodies interested in this matter may develop a plan which, either alone or combined with that of affixing metal tags through the shank bones, would still further protect the customer. The committee were impressed with the fact that, owing to the greater thickness of the skin, the application of cautery to the sides of the animal was attended with considerably less injury both to skin and flesh than was the case with the shoulders or legs.

The National Telephone Company.—The *Pall Mall Gazette* states: "For recuperative energy the National Telephone Company is a difficult corporation to beat. It has survived the execrations of its London subscribers; seen the birth and ignominious extinction of the New Telephone Company, which was organised to crush it; passed through unsuccessful lawsuits that would have ruined any other company, and successful ones that would have broken a bank; it is in a fair way to elude the action of the new model tramway (electric) clauses for at least three years; and now an uneasy feeling is abroad that it has diddled the whole country over the negotiations for the national purchase of trunk lines, pocketing no inconsiderable portion of the sum voted, and handing over in return the one portion of its system which could not by any possibility ever pay by itself, and which it would be glad to be rid of at any price."

Technical Education.—The London County Council has issued circulars relating to their scheme of technical education, which is under the supervision of Prof. Garnett. Beside giving 200 minor scholarships to pupils from elementary schools, and inaugurating classes for cookery and dressmaking, it is intended to aid the evening science classes held within the administrative county of London. This aid will take the form of a payment for each student attending certain classes a stated number of times, also an additional grant for maintenance of laboratory. These payments are made in addition to the grants received from the Science and Arts Department. The special subjects mentioned for which assistance is to be given are mathematics, theoretical and applied mechanics, practical geometry, building construction, machine drawing, naval architecture, chemistry (inorganic and organic), physics, botany, geology, mineralogy, steam, navigation, and nautical astronomy.

Long-Distance Telephony.—In the *Philosophical Magazine* for August, Prof. Perry, assisted by H. A. Beeston, has a paper on "Long-Distance Telephony," treated from the mathematical point of view. As it is given to few men, he says, to discuss complicated mathematical formulæ without making mistakes, he has instructed his pupils to experiment with their formulæ, using numerical values for their variables. Some of his students have recently obtained numerical results which are embodied in tables given in this paper. The tables show the limiting distances in millions of centimetres for various amounts of leakage and self-induction (one million centimetres is equal to about six miles). Other tables give numbers which, divided by $\sqrt{kr}$ for any telephonic line, and also by the value, m (depending on the allowable variation), considered suitable, will give the limiting distances for that conductor. These tables neglect terminal conditions.

Electric Light and Cooking by Gas.—Towards the conclusion of a paper on "Cooking by Gas," read by Mr. J. Ballantyne before the North British Association of Gas Managers, the author said: "One thing is certain, that should the electric light become the light of the future (as it no doubt will to a certain extent in the course of time) those towns which have been fostering cooking and heating by gas will come out of the struggle with least loss. In our case, suppose we lost the whole 20 million cubic feet of gas now required for lighting purposes, we should still require to manufacture at least 12 millions for our gas stoves. This, then, is the weapon with which to fight the electric light. If this branch of our business were pushed as it might be, we need have no fear of seeing the electric light introduced, because all that would be more than regained by the gas required for cooking and heating purposes." This is a very candid statement, but the author has left out of consideration the subject of cooking by electricity.

Lighting at Halifax.—The application of the Town Council for permission to borrow £30,000 for the construction of a central station was considered on Wednesday by Colonel Hasted, R.E., on behalf of the Local Government Board. The application is made under a provisional order, and the scheme has been prepared by Mr. Wilmhurst, and approved by Mr. W. H. Preece. The permissive area of supply is the whole of the county borough, but the compulsory area is certain streets within the borough. The plant proposed to be put down at first will be sufficient for about 10,000 lights. The application was opposed on behalf of several ratepayers and the Halifax Electric Light and Power Company. The latter was formed in 1889, and had expended £6,000 in supplying a portion of the borough with the electric light. The company would have opposed the granting of the provisional order had they not received certain assurances.

Rheostats.—The carrying capacity and resistance of hot wires for use as rheostats are, says *Industries and Iron*, worthy of investigation. If iron is used there is an uncertainty about the temperature coefficient and the specific resistance, so that it is difficult to know beforehand what a given set of spirals will do. If a more expensive metal or alloy is used, what is wanted is to get the largest surface with the least metal—that is to say, the wires should be as thin as is compatible with mechanical strength and durability. This is often overlooked, and resistances for large currents are made of large wire, whereas several small wires in parallel would be cheaper. It is most important that rheostats for testing work should be made up to exact resistances or conductivities; so that in testing, say, a 100-volt machine, the current may be exactly 100 times the conductivity of the circuit arranged. This dispenses with an ampere-meter, a matter of great convenience, especially when the currents are large. The information wanted is the carrying capacity of spirals of different pitches and diameters of wires of different gauges of copper and various definite alloys.

Dead Wires.—Seeing that the National Telephone Company may be said to have won all along the line in regard to all competitors, it may be worth while to ask what is being or will be done with regard to the many dead wires which are to be found all over the kingdom. If there is any danger in overhead wires—and we do not think this will be denied—the greatest danger is from those which are not continually under supervision, and particularly among these are those known as dead wires—that is, which have been used, but for some reason or other have been given up. We quite understand that it is always convenient for the company to disconnect these wires, because it may so happen that within a very short period some other subscriber will enable them to utilise such wires. Still, there remains a good few which have not been used for a considerable length of time. It has been suggested that if the use of overhead wires is to be continued no unused wires should remain *in situ* after the lapse of a certain time, and that the company should be compelled within the limits of this time to take down the wires, and so lessen the probability of accident.

Long-Distance Telephony.—Telephonic communication between Sweden and Norway will soon be established. The funds necessary for carrying out the work were voted by the Governments of the two countries in 1891, but for various reasons the carrying out of the scheme was deferred until this year. From Stockholm the telephone line passes *via* Oerebro, Karlstad, and Kongswinger to Christiania. The line is composed of a double copper wire 3·3 millimetres in diameter, and is suspended from the telegraph posts. It is anticipated that conversation will be rendered easy by the use of this type of wire between the Swedish and the Norwegian metropolis, and with the southern portion of Sweden. On the Swedish ground the line is connected with the State telephone network and with the system of the General Telephone Company, which uses double wires. On the Norwegian side, a public call office has been established at Kongswinger and a special call office at Christiania. A conversation of three minutes' duration between Stockholm and Christiania costs 1s. 10d.; the charge being double for six minutes. Telephonic communication is also about to be started between Sweden and Denmark, and the charge for conversation between Malmo and Copenhagen will be likewise 1s. 10d. per three minutes.

Comparison of Artificial Lights.—A series of comparisons has been made by Mr. C. Feldmann between the light obtained from different artificial sources and daylight. According to his conclusions, artificial light gives the most satisfactory results when under spectroscopic examination it approaches as near as possible daylight in the character of the rays. The arc lamp and the Auer incandescent gaslight are the artificial sources of light that approach sunlight most nearly in nature, but all artificial light has a warmer or more golden tint than daylight. Ordinary gas flames and low-power incandescent electric lamps emit the red and yellow rays in great excess, and are consequently still less satisfactory. The percentage of the total radiation that is received by the eye as light, varies greatly in different sources. It is lowest in the candle and the ordinary gas flame produced with a slit burner; it increases in the argand and regenerative burners, and in the Auer burner it reaches 20 times the percentage of effective radiation in the candle. With incandescent electric lights it is, however, slightly higher; and in the arc light as much as 80 times the proportion of radiation effective for lighting to the total radiation of a candle may be attained. The author suggests that suitable coloured reflectors attached to arc lamps would give a light closely approaching daylight in character.

A New Electric Railway.—This week the members of the Society of German Engineers, at their thirty-fourth annual meeting at Barmen, made an inspection of the mountain electric railway now completed in that town by Messrs. Siemens and Halske. The line is just over a mile long. It connects the centre of the town with the Barmen Wood and the elevated part near the Toelle Tower, and it affords a rapid means of transit towards the local pleasure grounds. The average gradient is 1 in 10, and the most severe is 1 in 5. The line is double throughout, and the gauge is 3ft. 4in. Each car accommodates 36 persons, and is equipped with two electric motors of 36 h.p. The motors actuate gearing which drives pinions gearing into the rack rail laid in the centre of the line. The current is collected from a copper conductor, as in the usual overhead trolley system, and after operating the motors, returns by the rails to the generating station in the town. The dynamos generate at 500 volts, and the overhead conductor is carried on transverse span wires fixed to iron pillars in the town and to wooden posts in the open ground. The cars are provided with three brakes, and there are four stations. The generating station has been designed with a view of dealing with the local supply of motive power, and for the operation of the electric tramways shortly to be constructed in the town.

Mid-African Telegraph.—This telegraph is intended to connect the Cape with Cairo, and contracts have already

been entered into to carry the line as far as Lake Nyassa. The section to the south of the Zambesi is to be made in the territory proper of the British South Africa Company, but the work of constructing the northern section in Nyassaland will be carried on under Mr. H. H. Johnston. The two sections when completed will meet at the point of junction selected upon the Zambesi. The whole length of line, for the construction of which the contracts have been signed, is 400 miles, and, in accordance with the decision to carry on construction from both ends at once, material for 200 miles has been sent to Chinde, while the material for the remaining 200 miles has been sent to Beira. The terminus at the northern end will be Zomba, near Blantyre, where Mr. Johnston has fixed the seat of government for Nyassaland. The line will be carried throughout upon iron poles, and at the point at which it crosses the Zambesi it will be carried to a height at which there will be no chance of the lines interfering with shipping. The work will be carried out in a spirit of the most friendly co-operation with Portugal, and in return for the right of using the already existing Portuguese wires to Quilimane, which establishes a branch connection with the eastern coast, the company will undertake to transmit Portuguese Government messages free of cost over their wires.

Electric Cooking.—The *Pall Mall Gazette* in a short article which savours of padding, and hard work for padding at that, says of electric cooking: "At present electric cooking is a fad. 'Tis true, 'tis pity; but pity 'tis 'tis true. Its merits are much talked about but seldom sampled. A delicate-handed lady will watch the broiling of the afore-mentioned cutlet with curiosity. She will prod it with a fork, and exclaim 'How delightful!' She feels on a sudden that here is something new; something she can show off to her friends in a dainty drawing-room at Bayswater. The absurdity of afternoon cutlets is self-evident, and she buys instead—an electric tea-kettle for occasional use. There is no thought whatever of a clean, convenient, economical method of cooking. No notion of its usefulness, no desire to try it crosses her mind. It is new, and therefore it is *chic*. It is a pretty toy. Yet if everyone would use electric cooking-stoves, or even gas-stoves, what a difference in the matter of fogs it would make to suffering London! Nothing but a course of plagues, followed by the simultaneous asphyxiation of all the firstborn, will ever instil into the breasts of the community such a communal idea as this. Let my neighbours all use smokeless stoves and welcome—each man says—then my one poor little kitchen fire will make no difference. And so say all of us—in London." It would be interesting to know any new departure that was not originally "a fad." It seems to us that many of the generally used notions nowadays were first of all obtained by the luxurious as luxuries, and descended like words from the drawing-room to the kitchen. It may be *chic* to have an electric tea-kettle, but as electric wires ramify from the mansion to the ordinary dwelling-house, so will electric kettles and other such-like paraphernalia.

Underground Telephone Wires in Manchester. The question of placing telephone wires underground in Manchester has not yet been settled. When the members of the City Council met on Wednesday the subject was warmly discussed. The Guardian Society for the Protection of Trade and the Chamber of Commerce had presented resolutions in relation to underground telephone wires. The former represented that the number of overhead wires already in existence had reached a point threatening the public safety. They were consequently of opinion that the time had arrived when all telephonic wires within the city should be laid in conduits underground, the Corporation reserving to itself the exclusive use of such conduits or the leasing thereof on such terms and conditions as it might prescribe; and, further, that in settling such terms and conditions, care should be taken to prevent the service becoming an absolute monopoly. They claimed, first, that the charge should not be more than would be sufficient to yield a reasonable return upon the cost of supplying the service; secondly, that every citizen prepared to pay the fixed charge should be secured in his right to demand the service; and, third, that the service should be constant and continuous. The memorial of the Chamber of Commerce expressed the opinion that it was essential that the Corporation should continue to retain complete control over the public streets. A resolution was moved that negotiations should be opened with the National Telephone Company on the subject of underground wires; but an amendment that, pending the result of certain negotiations at present in progress, and the consideration of the petitions of the Guardian Society and Chamber of Commerce, it was expedient that any action in placing telephone wires underground be postponed, was carried. Thus the matter stands at the present moment.

M. d'Arsonval's Experiments.—The experiments brought to the notice of the French Académie des Sciences by M. d'Arsonval on what he terms autoconduction of the body, have created a vivid interest in electrical circles. They bear on the same field as the celebrated experiments of Tesla. The body, or a part only, is placed in an oscillating magnetic field of very high frequency. This field is produced in the following manner: On a cylinder of insulating material (cardboard, wood, or glass, according to the dimensions of the apparatus) is wound in one or several layers an electric light cable carefully insulated. This constitutes a solenoid, in the interior of which the subject is placed. The solenoid is traversed by the discharge of a condenser rendered oscillating according to the process described in his paper to the Société de Physique (April 20, 1892). As condenser, two to twelve cylindrical Leyden jars are used, arranged in two batteries, connected in cascade, the covered surface being 50cm. high by 20cm. diameter. The charge is effected periodically by a transformer giving about 15,000 volts. This transformer is excited by a Siemens alternator, without iron, capable of giving a maximum of 12 amperes at 350 volts. The frequency is 60 periods per second. Under these conditions the inductive power of the solenoid on any conducting body placed inside it is truly astonishing, as the following experiments show: (1) Into a solenoid of three to five turns of a cable of eight strands of $8mm^2$ is placed a single turn of copper carrying a 100-c.p. lamp requiring three amperes at 100 volts; this lamp is brought to a dazzling brilliancy. (2) A man rounds his arm so as to embrace the solenoid, and takes in each hand one loop of an incandescent lamp. In the circuit formed by his arm a current is generated sufficiently strong to light a lamp taking 0·1 ampere. The resistance of the skin is diminished as much as possible by dipping them into two vessels containing warm salt water.

Consulting.—There is a point about which some consulting engineers are particularly sore. It is that too great generalisation is made in many of the reports that are given to local authorities. We agree that the practice is somewhat dangerous, and may lead to trouble. It is of comparatively little use telling an authority that one system will cost so much less or more than another system. What it wants to know is the system it must use, and the probable cost of that system. Great credit is ofttimes taken that a high-pressure transformer

sub-station system is far and away more economical than a low-pressure system. So perhaps it is in extreme cases; but in other cases there is not a pin to choose between the two as far as economy is concerned, and in other cases the low-pressure has the advantage. Far too great a stress is laid upon initial cost, rather than an accurate account of initial cost plus estimated cost of maintenance being given. Every week almost, if it was necessary, harsh criticisms might be made against the generalisations given in reports which can be proved to be more misleading than fit for acting upon. It is a frailty attributable to human nature that men in doubt like to get corroboration of views expressed; but "too many cooks spoil the broth" is an axiom that has a wide application, and reports upon reports are more likely to do harm than good. No two engineers would do any work in exactly the same way, yet either would do it well; so we still urge the principle of selecting a capable consulting engineer to prepare plans, and not to get report after report upon his performance. There are enough capable men to select from, and either would provide an excellent, economical, and workable scheme. Most of them indeed swear by economy, and thoroughly understand the difference between extra initial cost with cheapness of maintenance and less initial cost with an early ramshackle condition.

Welding Rail Joints.—In the course of a paper read before the American Street Railway Association, Mr. A. J. Moxham gave the results of experiments made at Johnstown, Pa., in the electric welding of very long rails. These experiments were carried out with rails joined solidly and held by heavy fishplates, and they demonstrated that for street rails buried in the ground expansion could be neglected. Subsequently 3,000ft. of line was welded solid, and although the track has been subject to a range of temperature of 30deg., no linear or lateral motion has been observed. This line was laid in May, and the welds were made with a specially-designed Thomson welder. Now, as mentioned in a previous issue, 16 miles of track at Cambridge are being welded. The track has been in constant use for two years, and the welding is being done without disturbing the track or paving, except to remove a few paving blocks at the rail joint. The rail is a heavy girder rail about 8in. deep. The old fishplates are first removed, and the ends of the rails freed from rust and scale by a hand emery-wheel on a flexible shaft and operated by an electric motor. A thin piece of steel of the same shape as the rail section is driven tightly between the rail ends to ensure contact. Then the joint is ready for welding. The current necessary to the operation of the car and plant is taken from the trolley wire over the track. This current is employed directly to propel the car, to operate the derrick by which the welding machine is moved, to run the emery-wheels before mentioned, and to actuate a large dynamotor inside the car. This machine takes the 500-volt direct current of the trolley wire and converts it into an alternating current of 300 volts potential. This alternating current is in turn conducted into a transformer, which reconverts it into a current estimated at four volts and 40,000 amperes. This current is then conducted from the transformer through 1,000 strips of copper to the secondary poles, and through the fishplates and the web of the rail. The forcing of this great current through the plates and rail causes heating sufficient to produce a white welding heat in two or three minutes. The poles in contact with the white-hot fishplates are kept cool by a jacketing of water circulated through pipes. When a welding heat is obtained the pressure is applied by a few revolutions of a hand-wheel, and the fishplates are forced against and cemented to the web of the rail. This pressure is accomplished by a system of levers. The poles of the transformer, the tie plate, and the web of the rail are between the lever jaws. By such an arrangement of levers and screws a small force applied to the hand-wheel exerts a pressure of 400,000lb. at the weld. Under this pressure a perfect union of the pieces is obtained and the welding completed. The current is then cut out, the machine is lifted by the electric derrick, and the operation is repeated at another joint.

Municipal Telephones.—The following is a copy of the application by the Glasgow Town Council to her Majesty's Postmaster-General for a telephone license: "The Lord Provost, Magistrates, and Council beg to apply to the Postmaster-General for the requisite license to empower them to establish a telephone exchange service within the city and Royal burgh of Glasgow. The applicants administer the municipal, police, and sanitary affairs of the city; have the control of the public parks and galleries; are the owners of the street tramways within the city and the suburbs thereof, and have power to work the same; manage the public markets and slaughter-houses, and carry out the Contagious Diseases (Animals) Acts, including the establishment of foreign animals' wharves, in terms of those Acts; as the Glasgow Water Commissioners they control the water supply of the city, and a widely extended area in its vicinity; as Gas Commissioners they have the sole right of manufacturing and supplying gas within the city and the adjacent burghs and districts; and they have also obtained a provisional order constituting them undertakers for the supply of electric light within the city. It is the opinion of the applicants that whenever the carrying on of any undertaking within the city necessitates the opening of streets and interference with drains, sewers, gas and water pipes, the control of such undertaking should be in the hands of the municipality. This opinion has again and again been given effect to by Parliament, not only in special legislation relating to Glasgow and other large towns, but in the general Acts empowering local authorities to establish gas, water, and electric lighting works, and to become owners of street tramways within their jurisdiction. The applicants submit that the principles which have been laid down by parliamentary committees, and by Parliament, with reference to these various matters are equally applicable to the establishment of a municipal telephone service. This view is confirmed by the report recently issued by the General Committee of the House of Lords and House of Commons on Electric Powers (Protective Clauses), one of whose recommendations is: 'The committee are of opinion that it is desirable in every way to facilitate the use of complete insulated metallic circuits for telephones, and for this end they recommend that statutory powers be granted enabling telephone undertakers to lay their wires underground.' The carrying out of this recommendation would place the telephone service in the same position as gas, water, and electric lighting undertakings. A cheap and effective telephone service is now recognised to be an absolute necessity in large business centres such as Glasgow, and the present service within the city does not meet the needs of the community. The service is not an efficient one, and the cost is excessive. It is also to be pointed out that the amenity of the city is being destroyed by the network of overhead wires running in all directions, which are also a source of no inconsiderable danger. The applicants are themselves the municipal authorities of the entire area for which a license is being applied, and consequently no consents under the Treasury minute of 23rd May, 1892, require to be produced."

WESTINGHOUSE DYNAMOS.

The Westinghouse Electric Company, whose name is a household word in the United States with reference to electric light and power, have one of the most complete organisations in the world for the supply of electric installations—from engines right through to lamps. While, of course, the work of the company is greatest in their own country, work of all kind is going on all over the world in the erection of stations, supply of power-transmission plant, transformers, and meters. In the erection of stations there is not so much doing at the present time in Europe by the Westinghouse Company, though, as is known, several large stations—Sardinia-street being the most noticeable—have been equipped. But in England and Europe generally a very large business is being done in transformers and meters—in fact, for meters, we suppose the supply of the Shallenberger meter is one of the largest businesses in England in this kind of apparatus. We saw recently a statement of four days' orders—8th to 12th of

Westinghouse Direct Current Railway Generator

this month—for 450 meters, perhaps rather an exceptional run, but one which serves to indicate the activity of this branch of the electrical business. Transformers also form a large branch of work, as the Westinghouse transformer has a deservedly good name for high efficiency and very small drop in the voltage between high and no load.

We have thought it would be interesting to illustrate a few of the most used types of dynamos and motors of the Westinghouse Company, now so largely employed in central light and power station work. Public attention has been turned to Chicago as the embodiment of American ingenuity and engineering skill. Here the Westinghouse Company shine conspicuously. It was this company that obtained the order for lighting the exhibition, and there are working at Chicago 12 1,000-h.p. generators, besides exciters and other machinery, making a total of some 13,000 h.p. used in driving the Westinghouse dynamos. The illustration shows one of these 1,000-h.p. machines belt-driven. There are six such machines direct coupled to Westinghouse engines, and six others driven by other people's engines by belts. One immense Corliss engine drives two of these latter dynamos, tandem fashion, with a "rider" belt—the largest instance on record of rider belt driving, being 2,000 h.p., transmitted by two belts running on the same engine pulley.

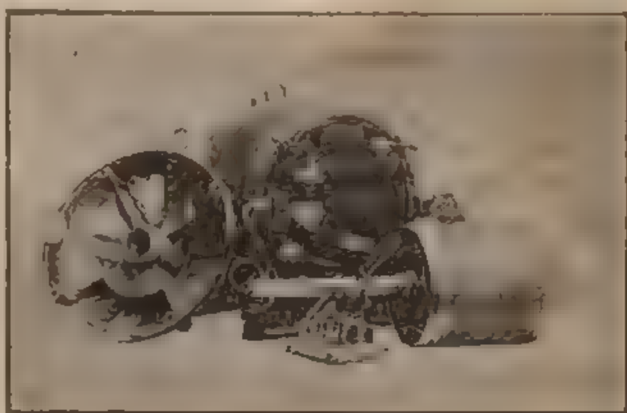
Each of these dynamos is capable of supplying 15,000 lamps of 16 c.p., so that with spare dynamos there are over 150,000 lamps lighted by the Westinghouse Company alone. The armature of these machines is double, in reality being two armatures side by side. It is about 8ft. high, and has very wide bearings. It is driven at 200 revolutions, and gives current at 2,000 volts.

Two Phase Tesla Motor.

These dynamos are all made self-regulating, to give constant potential at any load in a manner somewhat similar to compound windings—that is, by the means of coils whose special function is to increase or decrease the voltage as the load rises or falls. These dynamos are now being made for speeds as slow as 90 revolutions for 2,000 volts.

This Westinghouse alternator is used at Chicago for two-phase currents displaced a quarter of a phase for driving motors and power transmission generally. By a slight rearrangement of the armature on the shaft it will give the usual alternating current.

The switchboards used in conjunction with these dynamos are most magnificent affairs, built of white marble, and fitted with polished metal instruments enclosed in plate-glass frames. All the connections are made below the surface, and no contact can be made or shock obtained by the hands. The connections are made by double plugs fitting into holes making contact behind. In switching, all the connections are made before the current is switched over,



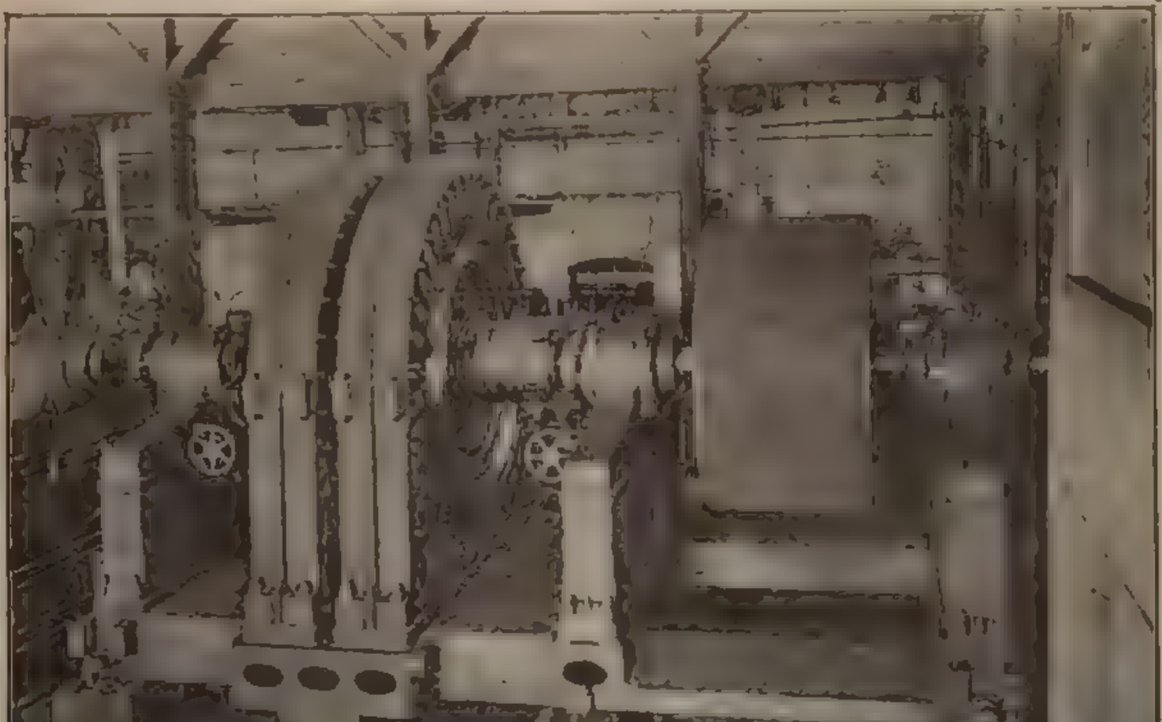
Tesla Motor in Parts.

and only when all the combinations are made and ready is the switch turned. This makes the switching very convenient and very safe. In the great switchboard at Chicago, there are over 1,000 instruments mounted on the white marble slabs.

Although for electric lighting the alternators are most used, for that other great branch of electrical engineering, electric railroads, direct-current generators and motors are, of course, employed. We illustrate one of the standard type of Westinghouse direct-current generators. These are made in four-pole type up to 250 h.p. or so, and to 500 h.p. in the six-pole pattern. Usually, these are compound

wound, with the shunt coils in series, and the four series coils in multiple. The four-pole machines have four carbon-brush holders, the two opposite brushes being cross connected. The six-pole machines have six brushes. These generators are very compact, and when joined to the Westinghouse engine on one bed plate make a most convenient form of railway generator. The company have recently issued a neat instruction book for engineers of railway generators which contains good rules for working such machines. It is to be noticed that fusible cut outs are not used, magnetic contact breakers being now always employed. In these a thick spiral of a turn or two keeps up a double-knife contact switch furnished with two side wings of thick carbon pencil, the latter rubbing against carbon plates. On excess of current passing, the armature is attracted, drops the switch, but the last break is made by the two carbon rods as they leave the carbon plates.

Westinghouse Alternator



1,000 h.p. Westinghouse Alternator used at Chicago.

An interesting engineering feature about all these dynamos and motors is that there is no winding apparent on the surface of the armature. The iron plates are

stamped out, and the coils are usually lathe-wound and slipped into slots on the armature, and then squeezed into shape by a special tool.

Amongst the most interesting of the Westinghouse productions stands the Tesla alternate-current motor. Very great things are expected of this motor, and Mr. Reginald Belfield, the Westinghouse Company's London engineer, at their offices, 32, Victoria street, Westminster, reports that, having seen the alternate current motors of Brown, Oerlikon, and others in Europe, the Westinghouse Tesla motor has proved itself far more practical that any that he has yet seen in Europe. The Tesla motors are made in two general styles—small motors up to 10 h.p. on the simple two-phase system, and large motors up to 500 h.p. or so of a combined alternate current now exhibited for the first time in Chicago. We illustrate the small Tesla motor as it appears in work, and also taken to pieces showing the armature. The motor starts with a very strong torque, and usually starts easily at full load.

It will be remembered that the Westinghouse Company have recently started a 10 000-volt power transmission plant at Pomona for transmission 28 miles, which we have already mentioned. This important installation is on the two-phase system, with the new motors. We think there might be a good deal of such work done in England if any engineer were audacious enough to introduce the two-phase currents, as this system is found better than the three-phase for lighting, and very much more convenient for motors.

Not content, however, with the simple alternate-current system—single-phase or two-phase—the Westinghouse Company are now perfecting a combined system of alternate and direct current distribution which will bid fair to revolutionise present methods. With the combined two-phase machines they can produce not only high-pressure alternating current for transmission and low pressure for lighting, but current for alternate-current motors, and also, by special transforming arrangements, low pressure direct current for charging accumulators, for ordinary motors, or for chemical decomposition. The system holds out great promises for the future. For it can, we think, be said that only when such a complete installation is at work for town supply, and for every purpose that customers can desire, are engineers making the fullest use of all the advantages of a central system of electrical distribution.

THE PRACTICAL MEASUREMENT OF ALTERNATING ELECTRIC CURRENTS.*

BY PROF. J. A. FLEMING, M.A., D.SC., F.R.S.

LECTURE I.

THE MEASUREMENT OF ALTERNATING CURRENT STRENGTH.

The subject on which I have undertaken to speak to you in this and three succeeding lectures is the practical measurement of alternating electric currents. The limits of time at our disposal will not permit me to deal with the question of electric measurements in general, far less to discuss the elementary principles on which all such measurements depend. I shall take it for granted that you are, at any rate, familiar with the fundamental facts concerning the production of electric currents, and most, if not all of you, familiar with the processes and instruments used in the measurement of continuous or unvarying currents.

The measurement of alternating or periodic currents involves processes and ideas which are somewhat more difficult to master than the simple conceptions which are sufficient to guide us in dealing with unvarying currents. It is towards the elucidation of these special difficulties that these lectures will be directed; and, keeping in view the special requirements of practical engineers dealing with alternating currents, I shall address myself entirely to the practical question of measurement, leaving out of account altogether theoretical matters. The practical measurement of alternating currents is a very important subject, because probably by far the larger portion of the electric lighting of the world is now conducted with alternating currents, and some of the largest schemes of transmission of power that are in process of development or already completed are being carried out by means of alternating currents.

Our first duty will be to begin with some familiar definitions which will make clear the meaning of the terms to be employed. When a conductor is traversed by an electric current we know that certain physical effects are produced. We know nothing about the real nature of an electric current. All that we can do is to measure the degree or amount of the physical effects it produces. Two of these effects are at once evident on very simple investigation—namely, that the current heats the conductor and produces around it a magnetic field. The moment we begin to investigate these effects we find that the electric current may be either in a variable state in which progressive changes are taking place in the effects produced by that current, or it may be a steady or unvarying condition in which the effects remain constant; or it may give evidence of being periodic in its nature—that is to say, the electric current may vary in strength and in direction in a periodic manner. When any cycle of operations takes place in such a way that any given effect runs through a series of changes, we speak of the periodic time of that effect, meaning by that term the time in which the whole cycle of operations is completed. Also we speak of the frequency of the change, meaning by that term the number of cycles completed in a second. A familiar illustration of the use of these terms may be drawn from music. In the case of a musical sound, the string or the air in the pipe runs through a certain cycle of movement, and the periodic time of the note is the time of completion of one complete vibration of the string or of the particles of the air; the frequency is the number of complete vibrations per second. The middle C of the piano has, or may have, a frequency of 256, the octave below that 128, the octave below that 64. In the case of electric currents which are periodic, the strength of the electric current is changing from instant to instant, and it is periodically reversed in direction. Applying the above terms, we speak of the frequency of the current, meaning the number of complete cycles in a second. For instance, the alternating current supplied to this lecture room from Deptford has a frequency of about 84, which corresponds to the lower F on the bass clef. The currents employed in the electric lighting of Rome are about an octave lower—namely, 40 in frequency.

You may picture to yourselves the difference between a continuous and an alternating current as similar to the difference between a non-tidal and a tidal river. In the case of a non-tidal river the waters flow on always in one direction—down the river; but in the case of a tidal river, such as the Thames at London Bridge, the direction of the flow of the water is periodically reversed. When we are dealing with periodic currents or periodic E.M.F.'s, it is very convenient to represent these by means of current curves or E.M.F. curves. To do this we take a horizontal line to represent the periodic time of the current, and dividing this line into a number of small equal parts, we erect perpendiculars at each point, proportional to the strength of the current or to the E.M.F. at that instant; joining the tops of these lines by a curve, we have an E.M.F. or current curve. We then may speak of the instantaneous value of the current or E.M.F., meaning thereby the value it has at any instant, or we may speak of the mean value of the current or E.M.F., meaning thereby the average value which it has during the period. It is also necessary to consider another, a rather more complicated kind of average, which is called the square root of the mean square value. This is obtained by taking the mean of the squares of all the instantaneous values taken at the equidistant intervals during the period, and then taking the square root of this mean value. To avoid constant repetition of this cumbersome phrase, the square root of the mean of the squares of the equidistant values during the period, we shall call it shortly the $\sqrt{\text{mean square}}$ value of the current or E.M.F.

Presently we shall see why it is that certain instruments give us this $\sqrt{\text{mean square}}$ value. It is important, sometimes, to be able to draw these current curves for any alternating current, and this has been done by many observers, notably by Duncan, Ryan, and Hopkinson.

In Fig. 1 we have a diagram of an apparatus used for this purpose by Dr. Hopkinson. On the shaft of an alternator is placed an ebonite disc, having at one point on its circumference a narrow feather of brass laid in. As the ebonite disc is carried round by the machine the brass edge is made to complete the circuit between two metallic brushes, which press against the ebonite disc, and the instant when this occurs can be determined by varying the position of the brushes. By connecting an electrometer with these brushes in the manner shown in Fig. 2, the electrometer gives us the measure by its deflection of the instantaneous value of the E.M.F. of the machine at that one particular instant. By shifting the position of the brushes we can measure the E.M.F. at equidistant intervals during the period, and then plot out the E.M.F. curve. In the same way, by measuring the instantaneous value of the potential difference between the ends of the resistance traversed by an alternating current, we can delineate the form of the current curve for that particular current.

In Fig. 3 are shown E.M.F. and current curves for a particular alternator, and it will be seen that they are highly irregular curves. We have, in the next place, to understand what it is that we are able in general to measure in dealing with alternating currents. When the alternating current flows through a wire, we may, by means of the instrument above described, determine the instantaneous values of that current. But this is not what, in general, we wish to do, neither are we much concerned with the true mean value of that alternating current. In by far the larger number of cases, the only thing that we want to know, and the only thing that we are able to measure, is the $\sqrt{\text{mean square}}$ value above explained.

When an electric current flows through a wire it heats it, and the rate of production of heat is any instant proportional to the square of the current strength. Hence, if the current strength is

* Cantor lectures, delivered before the Society of Arts.

changing from instant to instant, the total quantity of heat produced in the wire in any given time is proportional to the mean of the square of the current strength. Under fixed conditions the temperature which the wire will assume will depend upon this mean square value of the current; for the wire attains its final temperature when there is a balance between the rate at which the heat generated in it and the rate at which the heat has lost by it. The wire loses heat in three ways by convection, by radiation, and by conduction. If a wire is enclosed in a tube in such a way that convection is prevented, then the wire attains a final state of temperature, when there is a balance between the rate at which the wire loses heat by radiation and gains it by internal generation. Under these conditions, the temperature, and therefore the length of the wire, is determined, not by the average, but by the mean square of the current strength. If, therefore, the current is an alternating current, the final temperature, and therefore the length of the wire, enables us to measure this mean square value of the current. In the same way if two conductors, one of which is fixed and the other movable, are traversed by the same electric current, the electro-dynamic repulsion or attraction between these two conductors, due to the

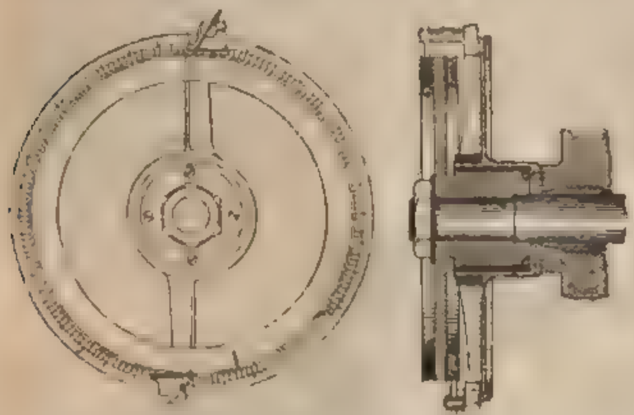


FIG. 1.

magnetic field around them becomes a measure of the same mean square value of the current, for at any instant the stress between the conductors is proportional to the square of the current strength flowing through them, and if the current is varying from moment to moment the average value of this stress is a measure of the mean of the square of the current strength. We may therefore employ either of these two physical effects, the heating of a wire by a current, or the mutual stress between two conductors traversed by the same current, to measure the mean square value of that periodic current.

So much being understood, it is now possible to point out to you what we mean by an alternating current of one ampere. A continuous current of one ampere has been defined by the Board of Trade Committee as an unvarying current of electricity which, when passed through a solution of silver salt, deposits ·001118 grammes of silver per second, or 4·0248 grammes per hour. This may be taken as the practical definition of what is meant by an electrical current having a strength of one ampere when that

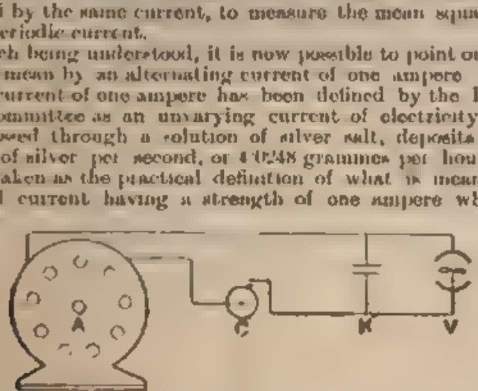

FIG. 2.

current is an unvarying current. An alternating current cannot, however, be estimated by such an electro-chemical method, but it is defined as follows: An alternating current of one ampere is understood to be a periodic current which, when passed through a conductor, brings this conductor to the same final steady temperature as an unvarying current of one ampere would do when passed through it under the same conditions. It is therefore an alternating current whose $\sqrt{}$ mean square value is unity, assuming the instantaneous values to be measured in fractions or multiples of an ampere. Having defined our unit of alternating current, and the two particular general methods of the $\sqrt{}$ mean square value, I may show you two experiments illustrating these facts.

Before me is an instrument which I have designed for some other purposes, but which is practically an apparatus for the measurement of the expansion of a wire. If you look at it you will see it consists of a wooden stand, A B, Fig. 4, having a sliding rod, *a*, at one end, pushed forward by a micrometer screw, M, and at the other end a system of levers, *c*, *d*, *e*, moving a mirror, *m*, from which a ray of light is reflected on to the screen. The micrometer rod and the system of levers are connected by a very fine copper wire, *w*, about 1½in long. On passing a continuous current of electricity through the wire, you see the spot of light on the screen changes its position, indicating that the wire has elongated. I can then, by means of the screw, bring the spot of light back to its old position, and thus measure the elongation of the wire, and therefore its mean temperature. Performing, then, the same experiment with an alternating current which is adjusted to give the same expansion to the wire, I know that I have now passing through the wire an alternating current of which the $\sqrt{}$ mean square value is equal to the value of the continuous current. Such a thermal instrument may be modified in many ways, and we shall presently see the forms it assumes; but in all of them the same principles are, in practice, employed.

In the next place, let me direct your attention to another apparatus, intended to illustrate the electro-dynamometer method of measuring alternating currents. An electro-dynamometer is an instrument which consists of two coils of wire, one of them fixed and the other movable. In the apparatus before you the movable coil is hung up by a steel wire. The movable coil is placed with

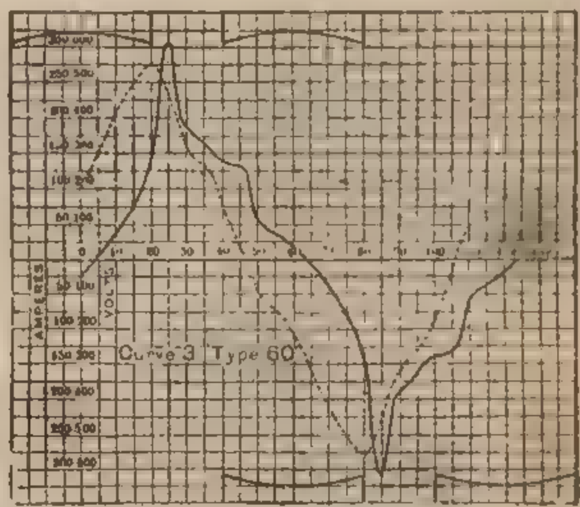

FIG. 3.

its axis at right angles to that of the fixed coil, and when one and the same current is passed through the coils, the movable coil tends to turn round so as to place its axis in line with that of the other; but by twisting round the suspending wire we can bring the coils back to their original position, and this amount of twisting is a measure of the mean square value of the current strength flowing through the coils. If, therefore, the current varies from instant to instant, the force which is required to hold the movable coil in any given position varies as the average of the square of the strength of the periodic current. Hence by means of these instruments, as by means of the hot-wire apparatus, we can measure the mean square value of the periodic current. Whilst I have this instrument before me I will point out one fact which is of practical importance. We know that if a copper plate is held in front of an alternating electromagnet it is repelled, and, similarly, if a copper plate is held near the movable coil of this dynamometer,

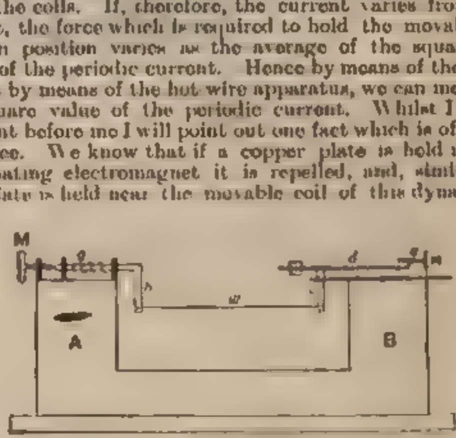

FIG. 4.

it in like manner repels the movable coil when that movable coil is traversed by an alternating current. I shall afterwards have to point out the practical importance of this fact. On the table before me are many different kinds of electro-dynamometers, which have been lent to me by Messrs. Siemens Bros., and you will be able to examine them afterwards; in each case you will see that there is a fixed coil or coils of wire which can be traversed by the current to be measured, and a suspended coil which is also traversed by the same current which passes through the fixed coil. The suspended coil is hung up by a steel spring which resists the movement of the movable coil. When the current passes through the instrument, the movable coil is twisted round, and the amount of torsion which has to be applied to it to bring it back to its original position is the measure of the mean square value of current strength.

Before going on to discuss in detail various classes of practical instruments which depend upon the principles just explained, it may be convenient to give here a brief classification of electric measuring instruments. The table below will show that these instruments may be classified into six divisions, depending on the kind of quantity they are intended to measure. They may also be classified into five species, depending on the particular physical principle which is employed in the instruments. It is not, however, every one of all possible varieties of such instruments that exists. Those instruments which have practically been made are indicated by + in the following table.

—	Electro-dynamic.	Electro-magnetic.	Electro-thermal.	Electro-chemical.	Electro-static.
Ammeters or current meters..	+	+	+		
Voltmeters or pressure meters	+	+	+		+
Ohmmeters or resistance meters		+			
Coloumb meters or quantity meters...				+	
Ergmetersorenergy meters.	+	+			
Wattmeters or power meters......	+	+			·

Taking, then, the first species of instruments—namely, those depending on electro-dynamic force -I will proceed to describe the valuable instruments invented by Lord Kelvin. Broadly speaking, these instruments may be described as electro dynamometers in which there are four fixed coils, around or between which are placed two movable coils attached to a balance arm. Before me on the table are some fine examples of the current balance lent by Messrs. James White and Co. The particular point to notice in these instruments is the manner in which the balance arm which carries the movable coils is suspended, so as to permit the coil to move freely, and will enable us to get the current into and out of the movable coils. Lord Kelvin solved that problem by the highly ingenious arrangement of suspending the balance arm by a large number of very fine copper wires. These flexible ligaments of copper are fixed at one end to a pair of fixed copper trunnions, and the other ends to projecting copper lugs attached to the balance arm. When the balance arm is in equilibrium the movable coils occupy a position between the fixed coils, and the connection of the circuits is such that the current can be passed through the whole of the coils in series. When this current so passes it brings into existence forces of attraction and repulsion between the fixed and movable coils, and the balance arm is tipped over in one direction. Equilibrium can then be restored by moving a sliding weight along a tray attached to the balance arm, and when the balance is obtained the position of this weight can be read by means of a scale. By the principles above explained the force required to hold the beam in its position of equilibrium is proportionally to the square of the current strength, and accordingly the beam can be graduated in such a manner as to read off currents directly. Fig. 5 shows the latest pattern of standard centi ampere balance.

(To be continued.)

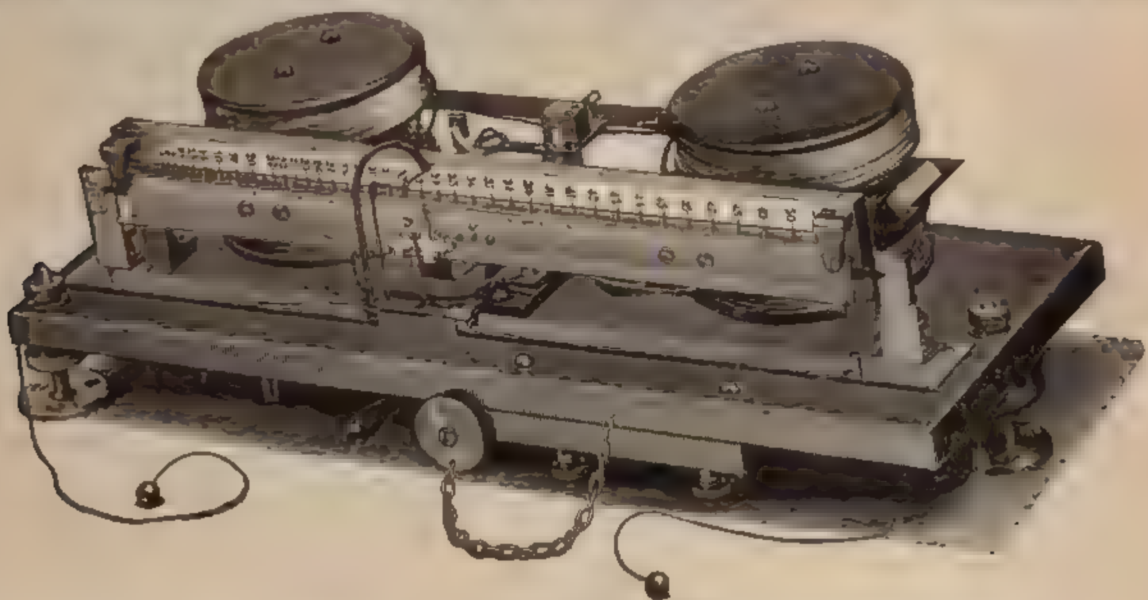

Fig. 5.—Standard Centi-Ampere Balance.

REPORT AND ACCOUNTS OF THE BRUSH CO.

Directors: J. B. Braithwaite, Esq., jun. (of Messrs. Foster and Braithwaite), chairman; Arthur Ayres, Esq., M Inst C.E., Aymor H. Sanderson, Esq., Colonel Frederick George Steuart, B H. Van Tromp, Esq., Edward Woods, Esq. (past president Institution of Civil Engineers). Joint Managers: John S. Raworth, M I E.E., and R. Percy Sellon, M I E.E.

Fourth annual report to be presented to the shareholders at the general meeting of the Company to be held at Cannon street Hotel, E.C., on Thursday, August 24, 1893, at 3 p m.

The profit and loss account shows a gross profit of £50,158. 6s., including the amount brought forward from last account, to which must be added £3,150. 12s. 2d., the balance of premium after payment of expenses arising from the additional preference and ordinary shares issued during the year. After deducting standing charges, maintenance of buildings, plant, and patents, interest on debenture stock, and the whole cost of concentrating the Company's works at Loughborough, amounting to £1,328 11s. 2d., there remains a balance of £26,394. 12s. 9d. to be dealt with. After providing the full dividend on the 6 per cent. preference shares for the year, and an interim dividend at the rate of 5 per cent. per annum, which has already been paid, on the ordinary shares for the half year ended December 31, 1892, the Directors recommend that the whole amount standing to the debit of preliminary expenses account, amounting to £1,575. 2s. 3d., be written off; and that a further dividend at the rate of 7 per cent. per annum be paid on the ordinary shares for the six months ended June 30, 1893, leaving £815. 5s. 3d. to be carried forward. The capital account has been increased during the year by the issue of 15,000 6 per cent. preference shares, and 11,617 ordinary shares, which have been fully subscribed. During the year the sum of £10,681 19s 10d. has been expended on capital account, chiefly in additional plant and buildings at Loughborough, and further extensions of the Company's works there are still in progress. These extensions have been rendered necessary by the increasing volume of central station plant which the Company are being called upon to manufacture. Good progress has been made with the construction of heavy plant for the Bankside station of the City of London Electric Lighting Company, the dynamos for which are each capable of supplying current for 15,000 incandescent lamps of 8 c.p. The first two of these are now delivered, and four more are in course of construction at Loughborough. During the past year the Directors have concluded a satisfactory arrangement with the Otis Elevator Company, of Mansion House-buildings, E.C., for the manufacture, at the Loughborough works, of the elevators and other appliances required by them. In view of the growing demand for electrically-worked lifts, arising from the introduction of electric supply into the leading towns of Great Britain and elsewhere, it is thought that the step which has been taken will prove of increasing advantage to your Company in the future. The home business of the Company generally continues in a healthy state, and the expiry of the Edison master incandescent lamp patent next November will probably give an additional impetus to central station development. Your Directors have made arrangements to resume the sale of incandescent lamps of their own manufacture as soon as the above Edison patent expires. The Australian branch of your business has naturally received a severe check owing to the late financial crisis in the Colonies, but your Company has sustained no loss through any of the bank failures which have taken place. In Austria your business shows a steady growth, and the factory is kept fully employed on continental orders. During the year the municipality of Temesvar has purchased your central station there. The amount thus received has been deducted from the property accounts of your foreign and colonial branches, a separate balance sheet of which is subjoined as usual. The outlook for the current year is good. Your works are at present fully employed and fresh orders are coming in well; whilst in the coming year the full benefit of the economies anticipated from the concentration of the Company's manufacturing operations at Loughborough should now be felt. It is believed that these economies will prove sufficient to provide the dividend upon the last issue of shares. The Directors deeply regret to record the loss by death of the late chairman—the Duke of Marlborough. The active interest he displayed in all questions affecting the electrical industry causes his loss to your Company to be the more keenly felt. Mr. J. B. Braithwaite has been elected chairman in his place. Mr. E. Garcke has resigned his position on the Board and, subject to the confirmation of the shareholders at the general meeting, Mr. Arthur Ayres has been elected to succeed him. Messrs. J. B. Braithwaite and B. H. Van Tromp retire by rotation, and, being legible, offer themselves for re-election. The auditors, Messrs. Cooper Bros. and Co., also retire and offer themselves for re-election.

Balance-sheet, June 30, 1893.

	£.	s.	d.	£.	s.	d.
Authorised capital	750,000	0	0			
Capital issued—viz., 90,000 6 per cent. preference shares of £2 each	180,000	0	0			
90,000 ordinary shares of £3 each	270,000	0	0			
	450,000	0	0			
Less calls unpaid	6,765	0	0			
				443,235	0	0
4½ per cent. perpetual debenture stock				125,000	0	0
Creditors—sundry debtors	35,660	5	2			
Bills payable	5,426	2	7			
				41,086	7	9
Reserve account, as per last account, less £1,550. 3s. 10d. applied during the year				1,529	16	11
Balance of profit and loss account	26,394	12	9			
Less interim dividend paid on preference and ordinary shares	10,500	0	0			
				15,894	12	9
				£626,745	17	5

Note.—Contingent liability in respect of uncalled capital on shares in other companies on guarantee and on bills receivable discounted, £9,429. 13s. 9d.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ACCUMULATOR TRACTION.

Sir,—"My powerful thirst for information" has at last drawn from the Epstein Accumulator Company, through the mouth of their prophet, Mr. Broekman, certain statements which I venture to think, when analysed, will be found to yield a no more valuable marketable commodity than that of froth.

Having satisfactorily proved to the electrical world that traction by Epstein accumulators is, in efficiency, durability, and economy of working, as well as in initial cost, the acme of perfection in their own opinion, *vide* Mr. Epstein's evidence before the Joint Committee and Mr. Broekman's letters, I trust that any remarks of mine in this letter will not dishearten them in trying to develop their system up to the summit of their ambition—viz., ebullition. "The never-failing regularity of accumulator traction" *versus* "the frequent irregularity of the direct system," does not appear to compensate the directors of the Birmingham Central Tramway Company, who, by their balance-sheet, inform us that although the Bristol-road section has a larger earning capacity per car mile than any other part of their system, yet the expenses per car mile are considerably higher than those of horse, cable, or steam traction, each of which they make use of. Of course, Mr. Epstein or his prophet might suggest that this was due to expensive and incompetent management, but as the same management is over each system, it is clear by parity of reasoning that the cost of motive power on the Bristol-road must be the highest.

Before passing to criticise the figures given by Mr. Broekman for the cost of motive power for accumulator traction, I do no more than suggest that any alleged advantages in efficiency must be greatly discounted by the increased weight of car, to which will have to be added the extra cost for wear and tear on the permanent way. I notice that the Epstein Accumulator Company are prepared to stand by the figures they have now given, to work any line at the cost of 3.928d. per car mile. This is to include fuel, oil and waste, brushes on motors, lubrication, wages at charging station, depreciation of buildings, and maintenance of accumulators; but I ask, what has become of car repairs and those necessary but expensive adjuncts to traction, drivers and conductors?

With these additions to Mr. Broekman's figures, it is significant that he is prepared to contract to work electric cars (for motive power only) at a price which is above the total cost of traction on the Leeds electric tramway, and about two-thirds more than the present cost of traction on the Liverpool overhead.—Yours, etc.,

London, S.W., Aug. 15, 1893. Stephen Sellon.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months
United Kingdom............	3s. 3d.	...	6s. 6d.	...	13s. 0d
Other Places..................	4s. 11d	...	9s. 9d.	..	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s*

THE OUTLOOK.

August is not a bad month to lazily look backwards or forwards, and to contemplate work that has been done or which is likely to be done. Since last year the air has cleared a bit—struggling firms have given up the ghost, and trade is getting on a firmer footing. There is still, however, too much cutting and too much work that is of a flimsy character. Gradually the majority have come to the opinion that to local authorities must we look for the future development of electric lighting and transmission of power. The gas interests are as rampageous as ever, attacking every loose statement, making the most of failures, dragging failures to the front and putting on one side all successes—trying, in fact, their level best to inculcate false notions in the minds of all who attend to their sayings. From most of those who favour gas, electricity has never had fair play, and we who advocate electrical work should recognise this, never allowing statements to pass without pointing out their one-sidedness. But to return to the present position of affairs and the immediate outlook. We have commenced during the past week or two a tabular statement showing the position of municipal electric lighting. This has been done in the interests of business men. The time has long passed when it was possible to keep the position of municipal matters secret, although in the earlier stages of negotiations every attempt is usually made to do so. The awakening of a local authority is often due to the initiative of some contracting firm or supply company, and the negotiations between these parties ought to be held somewhat sacred by competitors. Many a station has been delayed, many an arrangement spoilt by idiotic interference. It would be by no means difficult to pillory men now in active work who have been and are guilty of pushing into places already negotiating with others, promising to carry out the work at an impossible cost and for a smaller than ordinary remuneration. Generally, in the long run, the cost of the work is greater than it would have been in the hands of the original engineer. So much for interference; but there are places where the initiative comes from the local authority, and the matter is open to everybody without fear or favour. The opening of a small or large central station does not mean business only to the extent of the contracts. There is the wiring of houses and factories, the supply of electroliers, of lamps—arc and incandescent. There is, in fact, a new industry opened to the tradesmen of the town, and unless the electrical general factors are asleep, their travellers will soon open accounts in that town and supply the various materials that must be in constant demand. The ironmonger who keeps a stock of chandeliers will soon find it to his interest to keep a stock of electroliers. The big London firms cannot open branches everywhere, and though Edison-Swan may find it advantageous to do so, say, at Manchester, they will most likely prefer an account with a local man at Burton-on-Trent. A local authority, then, taking up electrical work thus

opens a number of doors for orders, and the ramification of the business developed is felt in many a centre of industry. At first the bulk of business may be small, but it increases, and must increase. There is much knowledge to be obtained by the earnest business enquiries that we cannot give—that we, in fact, honestly ought not to give. Take a piece of work at random, say at Nelson. This is a very enterprising, rising, prosperous Lancashire town, envied somewhat by its neighbours because of its rapid prosperity, all its actions watched critically and, if showing the shadow of success, followed. It owns the gasworks, but it also goes in for electrical work, and without a doubt various other towns will follow in its wake. It is not difficult for a business man to find out where these towns are, but it would be impossible for a journalist to give information. He can do nothing till a public sign is made, till the matter is mentioned in council or committee, and then if the business man is not already on the spot and in the swim he has been lax, and ought to find himself outside. The field is not open to suppliers of wire, lamps, fittings, and such-like apparatus till a later period, but it is best not to leave these matters too long, or the field may be found unprofitable. As we are showing in our table, there is a large amount of work under consideration. Plans are already under weigh for several important centres, and the successful opening of one station frequently causes other authorities to come to a definite decision to set to work, so that unless the unforeseen happens, the next year should see a fairly large number of stations commenced and completed. To the unemployed this should prove grateful tidings, for the equipment of these stations will need a certain number of electrical mechanical engineers, and, as we have previously said, the position of electrical engineer to a local authority will become one of the prizes of the profession.

GLOBULAR LIGHTNING.

SIR,—I am sending you an account of what appears to have been a very interesting case of globular lightning, as I am sure it will be of interest to some of your readers. The case referred to occurred at Dunchurch Hall, near Rugby. There had been a severe thunderstorm in the neighbourhood, and about three quarters of an hour after the last flash was seen, what looked like a ball of fire passed obliquely just over the house, struck a tree, which it cut into two pieces, and then exploded with an alarming report. The tree is about 20 yards from the house. Twenty-seven panes of glass were broken, and fragments of wood no larger than an ordinary chip were blown right over the house on to the drive, showing what a violent explosion must have taken place. Photographs of tree, with *débris* scattered about, have been taken.—Yours, etc.,

W. P. STEINTHAL.

32, Clarence-street, Loughborough.

ELECTROLYSIS OF PIPES.

SIR,—In your issue of the 11th inst. you give a note upon electrolysis of pipes, and quote from the *Canadian Architect* a method suggested for the protection of the pipes which to us seems entirely impracticable, on account of the amount of labour and great expense entailed in putting it into effect.

Permit us to point out to you that by coating the pipes with two coats of anti-sulphuric enamel a complete protection is assured. This material is an elastic composition which has been used for this purpose with the greatest success in many instances, as it is not only a perfect insulator, but being unaffected by acids, earth salts, and moisture, is superior to any other material that can be used for the purpose, and entirely dispenses with the covering of tarred hemp and two or three coats of a good hard elastic japan suggested by the *Canadian Architect*.

The "anti-sulphuric enamel" is an elastic composition which can be easily applied, and dries rapidly.—Yours, etc.,

GRIFFITHS BROS. AND CO.

Bermondsey, S.E., Aug. 16, 1893.

ELECTRIC LIGHTING OF LIGHTHOUSES.

In the course of a paper, read recently before the Maritime Congress, on "The Progress of Lighthouses," Mr. D. A. Stevenson, B.Sc., engineer to the Commissioners of Northern Lighthouses, referred as follows to the use of the electric light:

After many trials, the electric light was first exhibited from the South Foreland Lighthouse in December, 1858, the lamp used being that of Duboscq. Various inventors have improved the electric lamp, of whom Staite, Serrin, and Berjot are the chief; and the lamp most generally in use combines the essentials of the two last named. Various powerful machines exist, but it has been found that for lighthouse purposes a magneto-electric machine gives the best results, and that of De Meritens has been introduced at several lighthouses with excellent results.

The optical apparatus used with the electric arc at Dungeness (1862), La Heve (1865), Grisnez (1869), etc., were sixth order. In a report dated November, 1865, Messrs. Stevenson recommended the use of apparatus of the third order, and they further proposed to obtain the proper horizontal and vertical divergence by adopting Mr. T. Stevenson's differential lens suggested in 1860. The South Foreland (1872), Souter Point (1871), Lizard's (1878), are third order; Macquaire (1881), first order Tino (1884), Isle of May (1886), and St. Catherine's (1888) are second order.

There are now five electric lights on the coast of England, and one in Scotland. Between 1863 and 1885 eight electric lights had been established on the coasts of France, and the French authorities are still extending this system.

The relative penetrative powers of gas, oil, and electricity during fog formed the subject of careful photometric enquiry by Mr. H. B. Dixon, at the South Foreland experiments in 1885, and the results arrived at were as follows: "(1) That the oil and gas lights when shown through similar lenses are equally affected by atmospheric variations. (2) That the electric light is absorbed more largely by haze and fog than either the oil light or gas"; but that "in all weathers and at all distances its penetration has proved superior to the gas and oil lights." (3) That "all three are nearly equally affected by rain."

These conclusions have been amply verified in actual practice at lighthouses in Scotland. At midnight at each lighthouse in Scotland the keepers observe the lights which are visible in clear weather from their stations, and record in their journal whether they are visible or not. The following are the results of their records so far as they bear on this question:

	Times per annum.
Isle of May electric light was not seen from St. Abb's, distant 22 miles, on an average of four years	116
St. Abb's oil light was not seen from Isle of May on an average of four years	167
In favour of electric light	51
Isle of May electric light was not seen from Fidra, distant 10 miles, on an average of four years	59
Fidra oil light was not seen from Isle of May on an average of four years	134
In favour of electric light	75

Isle of May electric light was not seen from North Carr lightship, distant seven miles, on an average of four years	21
North Carr lightship was not seen from the Isle of May on an average of three years	135
In favour of electric light	114

St. Abb's Head is a first order eight-sided flashing light, using a five wick paraffin burner—one of the most powerful oil lights in the Northern Lighthouse Service.

The illumination of beacons by electricity conveyed by submarine wires was suggested by Messrs. Stevenson in 1854, and experiments were tried between the chain pier at Trinity and Granton breakwater, a distance of half a mile. The battery consisted of 16 Bunsen cells, and Wilde's electromagnetic machine was also tried. The results were satisfactory, but the experiments were not prosecuted, mainly on the score of cost. This proposal has now been fully realised at Gedney's Channel leading to New York Harbour. The electric station is at Sandy Hook, whence cables are led partly by overhead wires and partly by submarine cables to light six buoys for marking each side of Gedney's Channel, a beacon at Sandy Hook, and three buoys in the main channel. The lights are incandescent lamps of 100 c.p. each, shown from spar buoys about 50ft. in length, and rising 10ft. above the water. The power to work two dynamos is from 8 h.p. to 10 h.p.; normal voltage, 156; normal current, 29 amperes. The cost of the plant has been £2,913, while the maintenance is £683 yearly. The practical result of this better lighting of the approaches to New York Harbour is that the number of ships using it by night per month between 1889 and 1892 has doubled.

In the United States Lighthouse Service, electric lights, combined with dioptric apparatus, have been introduced in lightships. On each of the two masts there are four lanterns "hung on gimballs in brackets permanently fastened to each masthead. In each lantern is a 100 c.p. incandescent light. It is estimated that with the increased power due to the len's lanterns, the four lanterns at each masthead will give a total light equal to 4,000 c.p. Major Heap devised an exceedingly simple apparatus by means of which the lamps are extinguished and lighted automatically at definite intervals. Thus the light has the appearance of a flashing light."

MEANS OF DIMINISHING SPARKING IN CONTINUOUS-CURRENT DYNAMOS.*

BY W. C. RECHNIEWSKI.

We know that even in the best continuous-current machines it is necessary to shift the brushes to prevent sparking when the current varies. That a dynamo shall work well in practice it is necessary not only to find a non-sparking position for each current, but also that this position affords a certain margin on each side so that a small error in the position of the brushes is not prejudicial, and it is also requisite that the current may vary within large limits without necessitating the shifting of the brushes. The ideal would be to have no shifting at all at any load. A good machine may come near to this desideratum; we wish to study the means to achieve it.

There are two quite distinct phases of the problem to distinguish.

Suppose an armature traversed by a current, C; this current enters the circuit by one brush, divides in two, and becomes reunited at the other brush as it leaves the armature. The current in the sections of the armature is therefore C/2, and it changes its direction each time the coil passes the brushes.

1. For each given load of the dynamo there should exist a non-sparking position.

Theoretically, this position is that where, by the sole play of the E.M.F.'s acting on the coil short-circuited by the brush, the current in this coil is reversed and brought to its normal value, C/2, which it will have when the brush leaves the segment of the commutator.

* From *L'Electricien*.

If the brushes are too far back, the current will not have attained, at the moment of breaking the short circuit, the value C/2, which it should have after this; there will, therefore, be a sharp jump accompanied by sparking. If, on the contrary, the brushes are too far forward, the current in the coil will be not only reversed, but its value will exceed the C/2 which it will have after breaking the short circuit; there will, therefore, be a sharp change of current, and, consequently, sparking at the brushes. Figs. 1, 2, and 3 show these three cases. In these figures the abscissæ represent the displacement of the coils under the brushes; the ordinates the currents in the coil. The distance between the vertical lines represent the period during which the coils are in short circuit.

FIG. 1.

Fig. 1 shows the case in which the brushes are too forward, and the current has not attained the value C/2. In Fig. 2 the current has just reached, at the moment of breaking, the value it should have afterwards; while in Fig. 3 it has overstepped this limit. It is evident that Fig. 2 is the best.

FIG. 2.

We must remember that in order to make this position possible, and the same for all coils, the coils must be distributed very uniformly over its surface, and, further, that the difference of magnetic potential between the pole-pieces, expressed in ampere-turns, should be greater than the number of ampere-turns on the armature. These conditions are well known, and we need not further insist thereon.

2. But it is also necessary that the current, C, of the dynamo may vary without change in the position of the brushes; and the greater this variation the better will be the machine.

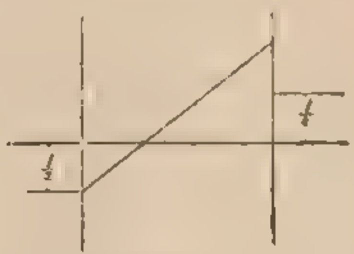

FIG. 3.

In motors, for instance, where the load varies constantly—tramway motors, travelling cranes, machine tools, etc.—the brushes cannot be constantly shifted: it is therefore very important that a great variation of load can be made without dangerous sparking.

Let us consider a position of the brushes which does not give rise to sparking, and let us vary the current. When the current increases, the magnetic field for the short-circuited coil ought to increase, in order that there should be no sparking, whereas, on the contrary, it decreases by reason of the reaction of the armature. The current in the short-circuited coil will not, therefore, have attained the value C/2 at the instant the brushes leave the commutator seg-

ment. At this moment there will be a sharp change of current, and consequently sparking.

The advantage is easily seen of rendering this reaction of the armature as low as possible; that is, of rendering the difference of magnetic potential between the armature and the pole-pieces expressed in ampere-turns as large as possible, relatively to the ampere-turns of the armature. Unfortunately, all sorts of practical considerations are against this, especially the question of price. We have, therefore, to turn to the other factors upon which we can act.

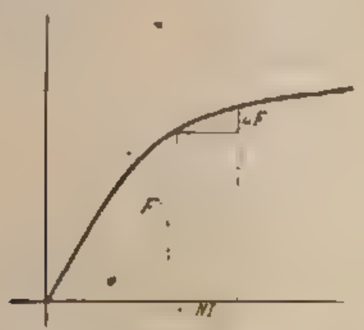

Fig. 4.

Each time the load varies above or below that for which the brushes are set, there will be a sudden change of current in the short-circuited coil at the moment of leaving the brushes. The change of current will be accompanied by a sudden change of flux which will rise to sparking, or a tendency to sparking, at the brushes. We may even say that the sparking will be in direct proportion to the variation of flux.

The problem therefore consists in making this change of flux as small as possible for a given change of current in the section passing under the brushes. To apply the results of the calculation to any machine, we must take the relation between this change of current in the short-circuited coil and the total current in the dynamo. Calling this current C, let us see, for instance, what would be the variation of flux when the current in the coil under the brushes changes from $-\frac{C}{2}$ to $+\frac{C}{2}$; that is, charges by C amperes. Call the number of turns in the coil N, and the variation of ampere-turns will be N C.

F being the flux of the dynamos at the moment considered, it will be easy to see on the characteristic, Fig. 4, to what change of flux, Δ F, the change, N C, in the excitation corresponds.

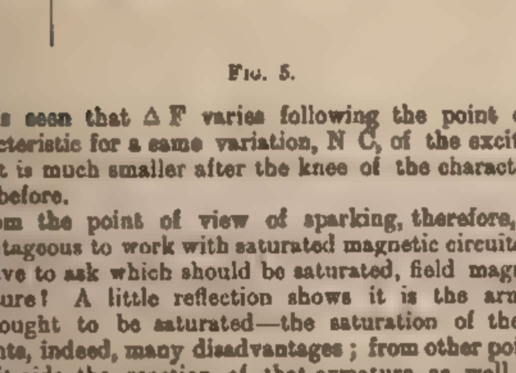

Fig. 5.

It is seen that Δ F varies following the point of the characteristic for a same variation, N C, of the excitation, that it is much smaller after the knee of the characteristic than before.

From the point of view of sparking, therefore, it is advantageous to work with saturated magnetic circuits; but we have to ask which should be saturated, field magnet or armature? A little reflection shows it is the armature that ought to be saturated—the saturation of the field presents, indeed, many disadvantages; from other points of view it aids the reaction of that armature as well as the lowering of the voltage which results therefrom when the load is raised, while saturation of the armature avoids many inconveniences.

It is often said that smooth-surfaced armatures spark less than toothed armatures. This might be true if we worked with armatures not saturated, or very little saturated. In Fig. 5, where *a* represents a characteristic with a toothed armature, and *b* with a smooth armature, this latter is much less steep at its first part before the bend than the curve *a*, because the magnetic resistance of a dynamo with smooth armature is much greater than one with toothed armature; and it is evident that for a change of excitation, N C, the change, Δ F, in the plan is much greater for a toothed armature than for a smooth armature. But matters are entirely changed when the bend of the curve is passed; indeed, once the armature is saturated the inclination of the characteristics becomes the same in the two cases, and consequently the variation of flux, Δ F, causes sparking, and as this state is arrived at much more rapidly with the toothed armature—that is, with less excitation—there is every advantage in employing it.

Instead of saturating the body of the armature, it is usually more advantageous to saturate the teeth themselves. Once the teeth are saturated the armature behaves exactly as if its air-gap had been increased by the height of the teeth—*i.e.*, had become much greater than that of the smooth armature; and as this is achieved with less excitation, there is an advantage in employing saturated teeth.

The figures indicating the tendency to spark will be therefore:

For ring winding in parallel—

$$\alpha \frac{F}{2}\frac{C}{2} = \frac{1}{4}\alpha F C.$$

For winding in series—

$$\alpha\, 2 \frac{F}{2} C = \alpha F C,$$

or four times greater.

For drum winding in parallel—

$$\alpha F \frac{C}{2} = \frac{1}{2}\alpha F C.$$

For drum winding in series—

$$\alpha . 2 F . C = 2 \alpha F C.$$

It is seen, therefore, for large machines, that the Gramme winding in parallel is the best, on the condition, of course, that only one turn per section is used. The combinations of windings which can be made for dynamos with six, eight, or more poles are still more numerous, but it is easy to apply to them the same reasoning.

(To be continued.)

ELECTRIC LIGHTING AT CHELTENHAM.

In our last issue we gave a brief account of the proceedings on the 8th inst. at the meeting of the Town Council of Cheltenham on the occasion of the presentation of the report of the Electric Lighting Committee by Mr. G. Norman, and we now give a more complete report. The minutes comprised an account of an interview between the members of the committee and Mr. Preece, F.R.S., with reference to the scheme for the lighting of Cheltenham. It will be remembered that when the reports sent in by Mr. Hall (the borough surveyor) and Prof. Ayrton, F.R.S., were discussed at a meeting of the Town Council in January last, it was suggested that a further opinion should be taken, and Mr. Preece was called in. The Mayor (Alderman J. C. Griffith) occupied the chair at the interview.

Mr. Preece. I have had just as much experience of the high-pressure system as the low pressure system, and I have recommended the low-pressure system where it is best from the engineering point of view, and I have recommended the high-pressure system where that is best from the engineering point of view. I have read with a great deal of care the reports of Mr. Hall and Prof. Ayrton. I have been over the ground, I have examined the place, and I have got all the information I could within the time at my disposal. I find your compulsory area extends over a considerable distance; I find that your anticipated clients are scattered about very much; and I have the strongest belief that the only satisfactory system which you could introduce here and with which you could give proper financial results is the high-pressure system. The low pressure system would mean that you would require a central station in the central part of the

town, and that you would have to expend a large sum of money in your mains. The high pressure system means that you could place your station anywhere and that you would not have to spend so much money in mains. And here you have special reasons, which I will give you by and by, why the destructor station is eminently and admirably adapted for a central electric light station, and where you could work it with economy on the high pressure system, and where you certainly, because you have the destructor always at work, have an element of considerable economy in the working expenses. I have no doubt whatever as to the system to be introduced here. It must be the high pressure system. The success of a gas industry is an indication of the success of electric lighting. There is no doubt as to the relative merits of the two lights. If you could supply anybody with the electric light at the same price he had to pay for gas, it is certain that people would take the electric light in preference to gas, not only because it has a brilliancy all its own, but because it is so health giving, and does not do the mischief to goods and decorations which gas sometimes does. So I say that by simply looking at the success of the gas industry here, you have an almost certain criterion of the success of your electric lighting industry. But when you come to the town itself, and go through the streets, and see the hotels, shops, Assembly rooms, theatre, Montpelier Gardens, why, long before you decide upon a certain scheme, long before your works are ready, and long before you turn on the current, you will have such a demand for the light that the amount of supply you now contemplate will not be sufficient. I am sure that you will have a return that will pay you very well, and I have no doubt that the prospect of business here is very encouraging. But the fear of most ordinary beings in connection with town councils is that they may have, at any rate for the first year or two, to incur a loss and fall back upon the rates to meet some deficiency. There is not a single instance on record where the electric light has been introduced where there has been any necessity to make a call upon the rates. In every single case where electric lighting has been introduced, the working expenses have been met, even in the first year.

Mr. Steel: Is that correct in regard to Ipswich?

Mr. Preece: The electric light has not been carried out by the Corporation at Ipswich. I am confining my remarks to installations carried out by corporations. There have been a great many companies who have carried out experimental installations which have been failures—cheap and nasty kind of things; but where a corporation has deliberately gone to work out a well-designed installation, or any installation, it has always proved a success, and I have not yet succeeded in finding one single failure.

Alderman Wethered: That does not include cases where the corporation has taken over the works from a company, but where the corporation has started the industry?

Mr. Preece: Yes, where they have started the industry. I mention this in particular, because the argument has been used "We shall have a tremendous loss the first year." Even your engineer, Mr. Hall, expects a loss on the first year. I don't. I think you will succeed in covering your working expenses. I won't go so far as to say that in the first year you will make sufficient to pay interest on the redemption fund; I will only say this, that you will cover your working expenses. You won't incur a loss which will compel you to come upon the rates, and in the second year there is not the slightest question you will clear sufficient to pay interest and to provide a sinking fund as well. So I don't see any reason why anybody should anticipate a loss when you start in a business which will meet your working expenses at the very first start of it. The next point I want to urge is, as to the relative cost of gas and electricity. Mr. Hall mentions electricity at 5d. per unit as equivalent to gas at 3s. 4d. per 1,000ft. I don't agree with that. I think he is on the wrong side. I have taken the mean consumption of all the electric lamps in England for 12 months. They number altogether nearly 900,000 lamps, so that when you take the mean of 900,000 lamps you are not far from the truth; and the mean consumption of those 900,000 lamps for the year 1892 was 18 units per annum. Eighteen units per annum at 6d. per unit means 9s., and therefore the mean cost per electric lamp—that is, a 35-watt lamp of 10 c.p.—is 9s. per annum. I have also taken out the gas returns of gas companies and gas corporations for 1890. I could not get any later returns of gas.

Mr. Woodard: That is street lamps?

Mr. Preece: No, the whole industry. It amounts to many millions of lamps, and it came out that the average consumption of gas per five cubic feet burner was 3,000 cubic feet per annum per gas burner. Well, the mean price of gas throughout the whole country is 3s. per 1,000ft., so that it comes out in this way. The mean consumption of gas being 3,000 cubic feet per burner at 3s. per 1,000, it brings the costs of a 10 c.p. lamp, whether burnt by electricity or gas, at exactly the same amount per annum—namely, 9s. So that I say that gas at 3s. per 1,000ft. is equivalent to electricity at 6d. per unit. Therefore, if you introduce your electricity at 6d. per unit you are introducing a light which is equivalent to gas at 3s. per 1,000ft. That is an argument based upon the behaviour of an enormous number of lamps—900,000 electric lamps and some millions of gas lights. And it is a very broad way of looking at the matter. I rather dwell upon this because it is a favourite thing to say that the electric light costs twice as much as gas. I am a gas shareholder as well as an electrical engineer, and if I were a gas engineer I should say this: Here you have gas giving you 15 c.p., so that five cubic feet would give a light which is equivalent to 15 candles, while your electric light is only 10 candles; therefore my gas is 50 per cent. better than your electric light; but that 15 c.p. is only obtained with great difficulty in the laboratory, with a specially designed sort of burner, great care to check the gas, great care that the pressure is exact, and the chemist or other person who makes the gas has to exercise the greatest care to get the full effect out of 5ft. In practice, if you take an ordinary burner, you will find that instead of it taking five cubic feet to give us your standard of 15 candles, five cubic feet gives only 10 candles. I have also made a series of exhaustive tests, and I can never get 10 c.p. So I say unhesitatingly, that an ordinary electric lamp burning 35 watts—that is a certain definite amount of electricity which is easily measured—gives the same light as an ordinary five cubic feet gas burner, so that the comparison, in making the 35 watt lamp and the five cubic feet gas burner each costing 9s. per annum, is a very fair and accurate comparison to make. But I rather went off the rails. I want to show that the gas engineer in making believe that the electric light is twice as dear as gas, shows the gas which he burns with a gas burner in a condition that it does not come up to the standard of light required by the Act. And then again, they also take into consideration this, that the two lamps are burning exactly the same time. Well, they are not. Most of you have your houses lighted with gas, and I have no doubt your experience is the same as mine. The servant goes round and lights up the whole of the rooms, and unless you exercise a strict supervision they are never turned down until put out. You don't think of turning down the light in the drawing room when you go in to dinner, consequently it burns to waste. With your electric lamp, however, the case is different. You have your switch at the door, and you instinctively get in the habit of turning it off, and instead of burning 600 hours a year, as the average gaslight burns in London, in private houses, and premises of a similar character, the electric light average is only 480 hours. So that you get 50 per cent. difference in the quality of the light and nearly 25 per cent. gain in the number of hours it is burning, and it is these two together which makes the difference. An electrical engineer could prove to you exactly how much you consumed. It really means this—that you must take the whole question in a very broad view. Don't take the figures as being my figures: take the figures of my friends the gas engineers and the gas journals. However, I think you will find my statements are justified. Another point is that the cost of the production of electricity and the working expenses is not a speculation—it is not even an estimate and a calculation, it is an absolute fact within the reach of everyone of us, and those who have had experience, as I have, will tell you to the smallest fraction of a farthing how much electricity costs to manufacture. At the Post Office, where we have 10,000 lamps, the cost of the production of electricity, including the maintenance of the lamps, is 2·45d. per unit. The cost generally in places where the light has been introduced comes out at about 4d. per unit. That is because so much is necessarily expended on mains. In carrying it over the area of a town like this, you have the mains to lay, and a certain amount of energy is lost in the mains, so that if you take it at 4d., which is a very fair average for the whole of the country, I think you are perfectly safe, and therefore you have got 2d. to your advantage if you charge 6d. to your clients. It costs you 4d., and you have 2d. profit, and therefore it comes to this: that the amount of your profit will simply depend upon the number of clients or customers you get. Mr. Hall shows you the cost of working and how many customers you think you may have, and after that it goes to profit. There is one point I should like to urge in connection with this, and that is that the larger your supply the greater the number of your customers, the cheaper per unit is the cost of production; and the longer you keep on the supply the cheaper—it is proportionately cheaper to run it four hours a day than two hours a day. If you can get clients to take the energy for motor purposes during the day you also reduce the cost of electric lighting, and, as I pointed out once, if it were possible to have the supply of electricity during the whole 24 hours—that is, supposing you have any industry that would take it the whole 24 hours—you could produce your electricity at the same price as gas would be at 2d. per 1,000ft. Of course, people cannot conceive gas at 2d. per thousand, but electricity at one third of a penny per unit is the same as gas at 2d. per thousand. There is an industry where the copper used for electric purposes is almost entirely obtained, and where the electricity is produced at a cost of one-third of a penny per unit. This has not convinced many of my gas friends, but it is a simple fact that the larger the production, and the longer the supply is kept on, the cheaper the cost, so that if you succeed in getting a large *clientele*, and if you have long use for the light, your cost would come to less than 4d. per unit, and you would be in a position to reduce the charge per unit to perhaps even less than 5d. The lowest charge at present made is 4½d. There is one other point on which I do not quite agree with your surveyor. I am a great advocate for public lighting, not on a large scale at first, but on a small scale, and lighting the most prominent spaces with the most brilliant and best arc lamps that are in the market. We find that at the Post Office that we get more work out of our men now that we have introduced the light, and that it pays for itself. At the Savings' Bank, where we have 1,500 employés, we have introduced the electric light, and the introduction of the electric light resulted in this—that the number of days' absences through sickness was diminished two days per head per annum, and the consequence was that we got 3,000 more days' work out of our staff in a year than before; and simply putting the cost at the lowest rate, the value of these 3,000 days was £700 odd, and the total cost of the electric light was £680, so that we get our light for nothing.

Mr. Norman: The advantages to be gained by the destructor site will more than compensate for the additional distance the mains will have to be laid as compared with the centre of the town?

Mr. Preece: Certainly, and I wanted to point out this, that one cause of the cost of the production of electricity is due to the fact that during the whole of the night and during the whole of the early morning and part of the daytime you are compelled to keep your current on, and that means a considerable waste of coal and energy. With your destructor there already at work, you have sufficient heat generally there to produce 50 h.p. or 60 h.p., and that is more than you want from, say, after 10 o'clock till 4 o'clock in the afternoon. That destructor will be worth ½d. or ¾d. per unit to you.

Mr. Norman: You have said, Mr. Preece, that you consider, under the circumstances of Cheltenham, that the high-pressure alternating current is the preferable system to adopt?

Mr. Preece: I have no doubt about it.

Mr. Norman: I should like to ask you whether you consider that the method of distribution—namely, that of delivering the high pressure current to transforming stations, and then serving the areas at low pressure—is preferable to placing the transformers at the houses?

Mr. Preece: Yes, to transform in the house would introduce an element of danger.

Mr. Norman: Then you endorse entirely what Prof. Ayrton recommends.

Mr. Preece: Yes, it is the only possible and practical way of carrying out the alternating current system.

Mr. Norman: I think I know your views upon this point. Your opinion is that lighting by electricity ought to be in the hands of the governing body of a town of a large population like this, and not in the hands of a private company?

Mr. Preece: Most distinctly. When it is the hands of a private company you have to deal with promotion money and directors' fees, you have to deal with dividends, and you have to deal with dividends of a much higher character than the interest you have to pay on money borrowed, you have people interested in the industry who might not be in the locality itself, whereas, when a corporation take it into its own hands you borrow money at a very low rate of interest, there is no promotion money to be paid, no directors' fees to pay, you will have all the organisation in your own hands, you have your own officers all there, and you strike away at once. Another element, when in the hands of a company, is the additional expense, and this is a tax upon the ratepayer—this extra expense as between a company and a town council. A company must also establish a sinking fund out of its profits, so that financially, all round, there is not one word to be said in favour of a company as against a corporation. There was something to be said in their favour in the earlier days of electric lighting, or at any rate there was something to be said against risking the ratepayers' money upon experiments; now there are no experiments to be paid for—it is a fixed industry, and if carried on properly is bound to pay.

Mr. Norman: Then there may be developments in the way of lamps and carbons, but do you think it possible that there could be any such improvements in the principle of the machinery, or is there any other factor that would make it desirable to wait?

Mr. Preece: There is practically little or no room for improvement. Machinery is manufactured with an efficiency of 94 per cent. If you get your plant it will give you an efficiency of 94 per cent., which means there is only 6 per cent. to work upon. The transforming parts have an efficiency of 98 per cent., so that there is no room for improvement there. The only place where improvement is coming is in the lamp, and there is little doubt that we shall have great improvement there. The patent for the incandescent lamp expires this year. We are now paying 3s. 9d. each for this lamp. I have already had offers of any number of lamps at 10d. each. The people themselves who hold the monopoly will probably bring their price down to 1s., and we shall get not only lamps whose price has been reduced from 3s. 9d. to 1s., but we shall get lamps supplied to us which will be infinitely better than the present ones. The lamp which you get now consumes four or five watts per candle; we now have offers of lamps to be supplied from Switzerland at 10d., which will give just the same result while consuming only 2½ watts per candle each. Therefore lamps will at the end of the year be obtainable not only at a cost reduced from 3s. 9d. to 1s., but we shall also have lamps giving the same results with an expenditure of only two-thirds of the present power. So that there is room for an immense economy.

Alderman Wethered: I understand you to say that in no case where a corporation has started electric lighting has there been any loss incurred? At Oxford (he believed) there is the low pressure system.

Mr. Preece: No; it is the high pressure system, but it is not the alternating current which they use. They have moving motors of a complicated and expensive character. I think you save yourselves a great deal of trouble by adopting the high-pressure alternating-current system.

Alderman Wethered: And the reason you recommend that system here is because of the scattered area of the town, over which I understand you went yesterday?

Mr. Preece: It is a scattered and an extensive area. It is simply a plain engineering question, and taking the engineering conditions into consideration, it is not a choice between high and low pressure; it is a necessity, not a choice.

Alderman Wethered: Then you believe the electric light is the light of the future, and that it is bound to supersede gas in the near future, and therefore if we were to allow a company to come in we should simply be letting a monopoly come in?

Mr. Preece: Distinctly.

Alderman Wethered: And that by introducing it ourselves we shall be not only saving the rates but preventing the setting up of another monopoly in the town.

Mr. Preece: Yes.

Mr. Norman: I see that in paragraph 21 of your report to the Corporation of Tunbridge Wells you say, "I do not know if ever your Corporation has had to consider the disposal of your own town refuse, but if the formation of a destructor has to be investigated, I think it is well to point out that the combination of a central station for electric lighting with a waste destructor would lead to a considerable economy in the manufacture of electrical energy, and ensure a considerable addition to the profits." That was in January last, so that the advantage of the use of a destructor in this connection was present in your mind before you had anything to do with Cheltenham?

Mr. Preece: I have tried to induce two or three corporations to introduce the light in reference to the destructor, and I think you have here an immense advantage in that you have got your destructor. You have got your shaft, your ground, the amount of money you have to spend upon your building is very small indeed. Mr. Hall does not estimate it at more than £1,600. If you came into the town for a place, you would not build a place for £5,000 that would be fit for a central station, and then you would have to spend another £5,000 on the mains, so that as against the high-pressure system you would have to spend on the low pressure system £10,000 more.

The **Mayor**: You know the town, and that it is divided into different residential districts, and you know the system of lighting proposed to be introduced. Do you think that Cheltenham is a suitable place for the introduction, the successful introduction, of the light, and do you think the measures we propose are wise and sound?

Mr. Preece: I do, most emphatically. I have never seen a town more suitable.

The **Mayor**: On behalf of the Electric Lighting Committee and on behalf of the Corporation, I beg to tender you our most sincere thanks.

At the meeting of the Town Council on the 8th inst., **Mr. Norman**, in proposing the adoption of the report of the Electric Lighting Committee, containing the above account, said its recommendations were as follows: "That the recommendations in Mr. Hall's report be carried out forthwith, reserving for further consideration the method and details of street lighting. That the town clerk do take the necessary steps to obtain the approval of the Board of Trade to the system proposed to be adopted and apply to the Local Government Board for sanction to a loan not exceeding £16,000. And that the surveyor do prepare the necessary specifications on which to obtain tenders for the execution of the works and the supply of the plant and electrical apparatus. The Council is now asked to approve of the proceeding of the committee and of this report." Continuing, he said that upon the opinion which Mr. Preece had given them, he (Mr. Norman) hoped he might challenge the unanimous verdict of the Council. They would see that Mr. Preece confirmed practically upon every point the recommendations of Mr. Hall and Prof. Ayrton. Over and over again he had approved the high pressure alternating system as the most suitable under the circumstances of the town; he had approved the method of transforming at sub stations as the only practical way, and he had approved of the destructor site unreservedly, and said it was likely to effect a saving of from ½d. to ¾d. per unit in the supply. Only on one point had Mr. Preece differed from what he understood the committee to recommend—that of public lighting, but the committee, in fact, had not abandoned the idea of public lighting, and had only postponed a final decision as to the method and detail of carrying it out.

The motion was seconded, and after considerable discussion the report was adopted, with one dissentient.

At the conclusion of the business of the Council a letter was read from the Brush Electrical Engineering Company, Limited, asking if the Corporation proposed to give effect to the provisional electric lighting order obtained by them, as, if not, it was the intention of the company to take steps to secure powers to enable them to undertake the supply of electricity throughout the borough of Cheltenham by means of a local company.

The town clerk was instructed to reply, informing the company of the resolution just arrived at.

BRADFORD.

Notes of Interview on Wednesday, July 19, 1893, between the Gas and Electricity Supply Committee and Lord Kelvin, as to Mode of Extension of Electricity Works and Mains.

Present: Alderman Frederick Priestman (in the chair), the Worshipful the Mayor (William Oddy, Esq.), Alderman Watmough, Councillor Kay (deputy chairman of committee), and Councillors Benn, Crossland, Freeman, J. Greenwood, North, Parker, Shaftoe, Toothill, L. Walker, and Watson.

The **Chairman** stated the reasons for which the interview had been arranged, and asked if the committee wished that Mr. Shoolbred and Mr. Baynes should be called into the room. It was decided that these gentlemen should be present at the interview.

The **Chairman**, after introducing Lord Kelvin to the committee, made a brief statement as to the erection of the present electrical installation, and pointed out that Bradford was the first municipal corporation to commence the supply of electricity to the public. The committee at the outset took great pains to get what, so far as they could see, was the best system. Mr. Shoolbred was appointed engineer at the time, and Dr. Hop-

kinson was called in to advise. The committee then felt justified in starting operations on the system which was adopted, though somewhat against Dr. Hopkinson's opinion. The doctor had then, as he has now, patents on the three-wire system, but it was decided to commence with the two-wire continuous current system. It was always kept in mind and was well understood that it might be advisable at some time in the future to adopt the three-wire system. Up to the present no hitch has arisen in connection with the supply, except that last winter the cables were overcharged with current beyond their capacity, and the light given off by the lamps was thus slightly impaired. As the season is so far advanced the committee came to the conclusion merely at the present moment to supplement the system by the expenditure of about £2,500 on additional plant. Mr. Baynes had expressed the wish that in the future he should be the electrical engineer, and acting under the instructions of the committee had prepared a report as to the proposed extensions. Mr. Shoolbred had also, in accordance with similar instructions, prepared a report on the subject. To judge between these two reports the committee had decided to call in an eminent scientist, and with that view the advice of Lord Kelvin had been sought. The view of the committee was not so much that either of the two reports before them should be adopted, but rather to be assured whether or not they were on the right track in what they had done and what they proposed to do. The committee would not have thought of asking Lord Kelvin's views on so small a matter as the spending of £2,500 or so, but as they are looking into the future, say, for the next 10 or 15 years, they wish to do now what will be found to be the best. The committee desired Lord Kelvin to say how far they have been right up to the present, and also what will be the best course for the future. His lordship had been shown over the works, and with the explanations which had been given to him would have a good knowledge of what had been done, and what the probable requirements of the town were likely to be. He would be glad to answer any questions his lordship might like to ask, and enquired whether he wished to make any additions to or observations on the report he had already presented.

Lord Kelvin, in reply to the Chairman, said he had already made a report, and that all he wished to add to it was as to the distance at which any second generating station might be placed from the present station. He had said $1\frac{1}{2}$ miles, and would like to say it should not be more than $1\frac{1}{2}$ miles from the present station, and might be nearer with advantage if found economical. That was the only point he cared to expand on at present.

The Chairman, having asked the committee what course they would adopt in their present enquiry, was deputed by the committee to ask of Lord Kelvin a series of questions which the Chairman stated he had prepared.

Councillor L. Walker hoped that that would not debar any member of the committee from asking any questions they thought fit to put.

The **Chairman** said certainly not. The committee wanted all the information they could get, and every member was requested to ask such questions as he considered necessary.

The Chairman thereupon proceeded to submit his enquiries, and they were dealt with as follows:

Lord Kelvin, in reply to the Chairman's question as to whether if Mr. Baynes's plan were adopted the committee would have to pay royalty on Dr. Hopkinson's patents, said that a royalty would probably have to be paid on the three-wire portion of the system. He could not say what would be the case as to royalty if the third wire were not brought back to the station, but if the wire were not brought back the working would not be so convenient.

Councillor Kay wished to know how much weight of cable was laid down, to which **Mr. Baynes** replied about 80 tons as cables exist at present.

Lord Kelvin, in reply to the Chairman, said the adoption of five-wire would not avoid royalty having to be paid, as by that system the return wires would have to be carried back to the dynamo. His lordship did not think the five-wire system impracticable or inadvisable in all cases, but in this case he would prefer the three-wire. If thought advisable afterwards, when experience had been gained, five-wire could be adopted. The five-wire was in use in Manchester, but if Bradford were starting *de novo* he would still advise three-wire as had been done. The committee had acted rightly in adopting the present system at the commencement of their undertaking. The possibility of adopting the three-wire system at a future time was fully considered when the works were at first laid down. The three-wire system would at that time have been premature with the comparatively small demand for the electric light then to be provided for. All that is known now was known then.

The **Chairman** said that apparently Lord Kelvin meant that if the three-wire were adopted now it could afterwards be converted, if thought advisable, to the five-wire. If the three-wire were adopted, would his lordship advise alternating or continuous current to be used?

Councillor Kay would like to know Lord Kelvin's views on that point in the event of the committee being able to get power from the Nidd water scheme.

Lord Kelvin said continuous current was undoubtedly preferable, even in high tension (say, 2,000 volts). If Bradford could get cheap power from some distance away, as suggested by Councillor Kay, even at four miles, from the new Nidd water supply, it might be advantageous to use alternating current, but he would prefer even then high-tension continuous current. Alternating currents were a success when a transformer was in use at each separate premises, but the use of transformers involved difficulties which did not arise with continuous current. The latter is better where there are varied requirements, as for charging accumulators, driving motors, electro-plating, etc. The alternating current is more difficult to transmit in large quantity than continuous current. Alternating motors were not yet well adapted for practical use. Asked what he would consider the best and most economical voltage if the new station were in operation, his lordship said that with such lamps as were at present in use he would recommend 250 volts, say 100 or 110 for houses, and 250 at the station.

The **Chairman** stated that the present voltage was 112, and asked if it would be advisable to change it in extending the operations.

Lord Kelvin thought it would not be advisable at present to alter the voltage supplied to the ordinary users. But any large user who would be content to have all his lights in pairs, lighted and extinguished together, might have 200 or 210 volts, and no third wire.

The **Chairman** asked if the potential would have to be raised, or the dynamos rewound or run in series.

Lord Kelvin said that in adopting the three-wire system he would prefer to run the dynamos in series at about 125 volts each, rather than rewind them for 250 volts each, but any additional dynamo which would be required should give 250 volts. The Board of Trade would now sanction 500 volts, but he considered 250 at the station best in present circumstances and for the future until lamps of higher voltage can be had economically.

The **Chairman** said that that completed his list of prepared questions as to future extensions, and asked if the committee wished to give Mr. Shoolbred the opportunity of making any remarks he wished upon the reports.

Councillor L. Walker thought that Mr. Shoolbred should not say anything.

The **Chairman** thought the object of the committee ought to be to get the best possible information in the matter, no matter from whom it was obtained. Mr. Shoolbred was thereupon requested to ask any questions he thought fit on the reports.

Mr. Shoolbred said he wished to draw the committee's attention to a letter he had sent to the town clerk as to alleged irregularities in regard to the placing of the reports before Lord Kelvin. He said that alterations and discrepancies had occurred, and he thought they ought to be explained to his lordship. He wished to say nothing of a personal nature, but objected to the introduction of fresh matter into the reports after they had been before the committee. He quoted from Lord Kelvin's report to show that the new matter had been supplied by Mr. Baynes after the reports were sent up to his lordship.

The **Chairman** objected to Mr. Shoolbred's remarks. The reports ought certainly to have contained the best possible information up to the latest possible moment. He understood, however, from Lord Kelvin, that Mr. Baynes's report mentioned all the points which his lordship would advise the committee to adopt.

Mr. Shoolbred stated that Manchester was not the only place where the five-wire system was applied, and he handed in a list of 15 electricity stations on the Continent where three-wire and five-wire systems were in use, having an output of over 20,000 h.p. The Chairman read particulars from the list.

Lord Kelvin remarked that the additional matter in Mr. Baynes's report to which Mr. Shoolbred took exception was merely supplied to elucidate certain points arising in the conference on the reports, and was promised by Mr. Baynes in Mr. Shoolbred's presence.

Councillor Shaftoe asked if three-wire system would be as economical as the present system.

Lord Kelvin said it would be more economical to adopt three-wire system, even including royalty, which was only a comparatively trifling matter. He could not say with certainty whether the patent would or would not be renewed on expiration two years hence. He considered that when the present works were started, five years ago, the committee had adopted the best system at the time in use. The three-wire at that time would have been of doubtful utility for practical use, and would have required more costly plant. Westminster had commenced on two-wire system and converted since to three-wire. This was not undoing any work, but simply extending their system. Taking all things into consideration, the Bradford Corporation did the best thing they could do at the time, although the three-wire system was in use before the Bradford works started, but was advisedly not adopted.

The **Chairman** said that if the three-wire system had been adopted in the first instance its greater cost would have simply killed the prospects of electricity in Bradford. From the very first the possibility of adopting the three-wire system at some time in the future had been fully borne in mind.

Mr. Shoolbred said that Leamington was the only place using three-wire when Bradford started their works.

Councillor Kay said that St. James's and Pall Mall started in May, 1889, and Bradford in September, 1889, but in reply it was stated that the scheme for Bradford had been settled before those dates.

The **Chairman** asked whether Lord Kelvin considered the short-stroke Willans type of engine or the Corliss type to be the best.

Lord Kelvin said that Willans or similar engines were certainly preferable to Corliss or similar type of engines which ran at slow speeds, with belt-driven or rope-driven dynamos.

Councillor Kay made enquiry as to the cost of coal per horse-power, and also as to gas engines with Dowson's gas plant.

Lord Kelvin could not say anything off hand as to coal consumption. As to gas engines, it might be advisable to make full enquiries, though he would scarcely advise decidedly their use on

his present knowledge. The fact that gas engines dispensed with boilers was one great advantage in their favour.

On **Councillor Benn** asking what disadvantages were found in Corliss type engines, his **Lordship** said they took up too much room. The work at present so well done in the Bradford supply station would be impossible in the same space with large slow speed engines and dynamos driven from them by ropes or belts. Willans and similar engines were also good in that with them each engine and dynamo started together. Willans engines have stood the test of many years use, and proved very economical. For non condensing engines Willans's in many cases are quite as economical as others.

The **Chairman** said that Mr. John Waugh was at Willans's works testing the new engine, and would also test the present engines at Bradford on his return.

Lord Kelvin said that Willans could at any time add another cylinder to their non condensing engines and make them into condensing.

In answer to Councillor Kay, his **Lordship** said that, given the number of units sold and the number of pounds of coal used in a year, it would be a difficult matter to tell the rate of consumption in proportion to true mechanical efficiency of the several engines. The number of electric units produced by the steam engines in the station is necessarily greater, considerably, than the number sold; the coal consumed in the station is of necessity much greater than what would be required to supply, in steady continuous work of 10 hours a day, the electric energy actually produced in the 24 hours.

The **Chairman**: Will you kindly say what you think of the Willans engines as compared with other types?

Lord Kelvin: The experience at electric lighting stations is very strongly in favour of Willans's. Kennedy finds them very good. The Metropolitan Company likes Willans's. The City of London Company uses engines similar in respect to speed and direct driving, though not by the same makers.

Councillor Kay said he had seen a report by Prof. Kennedy in which he strongly advocated the use of gas-engines, say, of 100 h.p.

Lord Kelvin said it was certainly one good point about gas engines that they could be started at once, without waiting to get up steam in case of sudden darkness. Air condensers had been tried, but not, he believed, with much success.

The **Chairman** enquired if it would be advisable to get the engines triplicated instead of sticking to compound. The cost of coal is now ¼ of 1d. for each unit we sell. The coal is little better than smudge, only costing 8s. 4d. per ton, whilst much better coal is used when making tests of engines to ascertain efficiency.

Lord Kelvin thought it probably not advisable, but it would be better to ask engine makers' opinions on that point.

The **Chairman** enquired as to boilers. In putting new ones down would it be advisable to run, say, at 180lb. (the present pressure is 140lb.) and tone down pressure to 140lb. when the boilers begin to age, working them out to feed the original engines which are built for the lower pressure?

Lord Kelvin said 180lb. would certainly be more economical than 140lb. He did not think that expenses for machinery repairs would be much larger owing to the higher pressure, but engine makers should be consulted.

The **Chairman** said that the station had been designed so as to admit of being four folded. Would it be advisable to place boilers on the upper floor?

Lord Kelvin said that that was done at Edison's great station in New York. It was not impracticable, but its advisability would depend on local circumstances, such as the ease with which coal could be got to the upper floor for use under the boilers there.

Mr. Baynes thought that in the above case moist steam would get into the cylinders, but his **Lordship** did not think that would be found a serious difficulty.

The **Chairman** asked what was the best kind of boiler to use. Those in use at present are Lancashire boilers with Galloway tubes. Also a small Babcock and Wilcox boiler but the latter primes easily and smokes a good deal.

Lord Kelvin thought that coke might be used for the Babcock boiler, which is good for rapidly getting up steam; but in other respects Lancashire boilers are preferable.

Councillor L. Walker thought that if Lord Kelvin recommended gas engines it would be advisable to put one down at once.

Lord Kelvin thought it would be wise to do so if on enquiry it were found to answer well elsewhere. In answer to the Chairman as to putting down gas plant or sticking to steam engines, his lordship thought it might possibly be best to stick to steam in the present station. But even in the present station a gas engine might possibly find a place advantageously with special view to sudden requirements, as in the case of a fog coming on suddenly. Gas might be used more largely at any new station, if found economical, as well as convenient.

Councillor Kay said that Dowson's gas could be made at Mill-street and brought down in a 3in. pipe.

Lord Kelvin, in answer to the Chairman, said he knew of no better dynamo than those the Bradford electric station had from Siemens's English firm. There was a German Siemens's firm, also. Messrs. Clark and Muirhead, and the Electric Construction Company, also made dynamos as good as the best. He knew nothing of Holmes's dynamos as yet. English made dynamos are quite as good as the best foreign make. Many English dynamos were, he believed, as good as Siemens's, which were certainly very good.

The **Chairman** enquired as to cables. Which was preferable – bare copper conductors or the ordinary sheathed cable? (Sample of cable at present used in Bradford was produced.)

Lord Kelvin said the present cable was very good, but the bare copper was better where circumstances allowed. It depended largely on the amount of piping, etc., already occupying the streets. With three wire system he would prefer culverts, if not much more costly.

Mr. Shoolbred explained that bare copper strips in culverts would be dearer than the underground cables as at present laid – that is, in the first instance. The culvert was of course preferable if expense be disregarded.

The **Chairman** asked whether, speaking broadly, his lordship would advise putting in culverts, or laying on the old system.

Lord Kelvin said he would go to the expense of culverts if not much in excess of the other. In Glasgow iron culverts were supplied under Kennedy. Irrespective of cost, the culvert was best.

The **Chairman**: If we found cables best at present would you recommend putting in culverts if the cost were double that at present?

Lord Kelvin said that taking into account all expense, the system of bare copper on insulators in culverts should not cost so much as double; indeed, for conductors above a certain size it costs not more than armoured cables, and actually less than armoured cables for the largest of the electric light conductors hitherto laid in towns. The bare copper strip cost less than insulated wire strand in the first instance, and lasts longer than may be expected of armoured cable laid in the ground. As to use of bitumen blocks, he should not think them better than the present system in Bradford, where the cables are laid in ashes. As to laying in iron pipes, there is no objection if the cable is well insulated and strongly enough protected against abrasion. The Bradford cables require more of mechanical protection than if laid in iron pipes, and this is supplied by the armour sheathing. As to cables, his lordship considered that the Silvertown cables were as good as Siemens's, and the British Insulated Wire Company's cables were good if the water could be kept out. The latter cable, although new, and not long tried as yet, is already very well spoken of. In it the insulator is of paper, encased in lead.

The **Chairman** next asked advice as to meters. As the next best after Lord Kelvin's own meter, which did his lordship think should be used for consumers?

Lord Kelvin would not say that his own meter was the best. Meters had presented much difficulty to the supply companies. He knew a case where two lamps could be used all night without the meter showing it at all. The Edison electrolytic meter was too troublesome. As to station meters, he thought it very proper to have a station meter on each dynamo to show how much work is delivered, and would recommend for this purpose either his own meter or that of Edmondson and Oulton, of which he had seen several specimens to day on trial at their Bradford station.

The **Chairman** asked about storage batteries. Which was best?

Lord Kelvin said a certain amount of storage power ought to be at any central station as a reserve. The E.P.S. battery is suited for steady work, but not where there are sudden great calls on the system. The Crompton Howell battery is better adapted for that purpose than the ordinary E.P.S. is. There may be other good batteries, but the Crompton Howell had been judged to be the best for electric supply stations up to the present.

The **Chairman** having asked if it were advisable to add to the present batteries, **Mr. Baynes** explained that the Bradford batteries only sufficed for one side of the third wire.

Lord Kelvin said it would certainly be useful to have an additional storage battery so that the whole voltage required for the three wire system might be had direct from a 250 volt battery. The plan of having the motor generator which he had referred to would allow the station to go on for a considerable part of the 24 hours, at a small rate of supply to users, with only the present battery without engines at all. The expense of a motor generator is small as compared with that of a fresh storage battery. His lordship added, I think it advisable to try a motor generator instead of going to any additional expense at present on storage batteries. Later it may be found, and no doubt will be found, that the storage capacity of the batteries is insufficient. But in view of the great cost of an additional battery I think it advisable to take for the present, and for some time to come, the motor generator. If superseded from its first purpose, the motor-generator could be converted into a steam generator. In view of the expenditure as at present proposed of so small a sum as £2,500, it is not advisable to think of additional batteries. It would be judicious to try the motor generator as recommended by Mr. Baynes. In cases also in which you may wish to run with only one steam dynamo, of 150 volts, this motor-generator would allow you to do so, on the three wire system.

Mr. Baynes said the motor generators he had recommended would have a capacity of 100 amperes each.

As to the charge for electricity to consumers, the **Chairman** said that the present price per unit was 5d. Would his lordship advise a reduction to 3d. or so for motive power during the day?

Lord Kelvin thought it was very desirable to reduce the price per unit to the users of motors during the daytime; 4d. per unit would induce many consumers, and 3d. would fetch more still.

Mr. Baynes thought it would not be a loss to supply at 3d. per unit for motors during the day, as the present cost for coal was only four tenths of a penny per unit.

Lord Kelvin thought the additional expenses involved in giving a day supply would be comparatively small, and if the daily supply were taken up, would justify the reduction in price, which would be for motive power only.

The **Chairman** stated that the present maximum output of the works was 4,800 amperes, and the demand last winter was 4,500 amperes, and he said the committee had had a considerable number

of applications for current this summer. Would Lord Kelvin think it safe or prudent to put any additional consumers on when the engines are now overloaded?

Lord Kelvin thought it would be imprudent to try to increase the output with the present plant. The breakdown even of a small engine would be a disaster, and power ought always to be kept in reserve for emergencies, so as to be able to switch it on at once.

Mr. Baynes, in reply to Councillor L. Walker, said there had been no expensive repairs in the engines. The most costly at any time had been about £12 in amount.

Lord Kelvin, in reply to the Chairman, said he would strongly advise the putting down at once of additional engine power at the present station. He would advise the putting down of a new steam dynamo at 250 volts, and of 300 h.p., which would provide considerable reserve power. He would rather have one of 300 h.p. than two of 150 h.p. each. A duplicate armature would be required for the new engine as at present.

Councillor L. Walker wished to know if Lord Kelvin distinctly recommended Willans engines, to which his **Lordship** said that, all things considered, he would recommend them, though there are other engines, similar in type, about as good. Willans engines have been proved to be good ones.

Councillor Kay asked whether, if Willans engines used 6lb. to 8lb. of coal per horse power, Lord Kelvin would consider them economical? **Lord Kelvin** replied, No.

The **Chairman** said that the town was at present a complete network of mains. If rats got to the cable they could cause a serious leakage, which was difficult to localise. In reply to a question in the matter,

Lord Kelvin said he thought it would be well to divide the town into cable districts so as to minimise the risk from leakages.

Mr. Shoolbred said the town had been originally so divided into sections by him.

Councillor L. Walker again asked if Lord Kelvin thought Willans engines the very best the committee could get, as he wished to be perfectly clear about the matter, to which he attached much importance.

Lord Kelvin replied that so far as he knew Willans engine was the one to be chosen, but he would not say that no other engine was as good. So far as can be judged at present, it is the best for the purpose.

Councillor L. Walker asked whether electricity was likely to be cheapened within the next five years, and **Lord Kelvin** said he thought it probable that that would be the case, and that the committee might be able to put the price at less than 5d. per unit with advantage all round. He was not sure whether the committee by acting on his present advice would cheapen the cost of electricity, but he thought that by enlarging the output by the use of the three wire system, and by making a larger market for the supply, it might be cheapened.

Councillor L. Walker wished to know whether electrical science had not made advances since Bradford commenced operations, and if so, how the present works could be improved. **Lord Kelvin** replied that except as to the application of the three wire system there could be no better arrangement for the present area than was adopted five years ago. There has been no advance in electrical science during the last four years which would warrant any other change from the present system than that now contemplated.

His **Lordship** said that if the committee did their work well and tried to extend their system that was about all they could do. He certainly thought that electricity would be cheaper within the next five years. Five years ago there were dynamos delivering 90 per cent. of the power put into them. Now there are dynamos giving out 95 per cent. Ordinary good dynamos, he thought, would give about 90 per cent. There is not much improvement to be made there, but the opportunity may arise of getting power cheaper. Willans engines, or other high speed direct driving engines, if condensing, will give cheaper power. There is practically no way of decreasing very much the cost to the consumer except by increasing the market.

Councillor L. Walker observed that the supply of electricity would not be very extensively used until it is as cheap as gas, and asked whether there is any likelihood of it being supplied at the same price as gas light for light.

The **Chairman** said he was surprised to hear Councillor Walker say so. If the electric light were generally adopted in the town, what about the gasworks with their £600,000 capital?

Lord Kelvin thought the prices of gas and electricity were not far apart even now. Fivepence per unit compared very favourably with the price of gas in many towns. Even if it cost double the price of gas in a town like Bradford, where gas is very cheap, light for light, many people would gladly pay the extra money, and could even then effect an economy, as the light when not wanted need not be left burning like gas, and it is much more cleanly, and far better for health. It did not injure the stock in shops, nor walls, ceilings, furniture, decorations, etc., in private houses, and there were many other advantages arising from the use of it.

Councillor L. Walker wished to know whether, if the works were started *de novo*, the current could be supplied cheaper than at present.

Lord Kelvin said he believed it could be supplied cheaper to-day if the committee wished to do so irrespective of the question of profit above bare interest on outlay, but he did not think they could have done better on the whole than they had done from the very outset.

Councillor Parker asked if his lordship would advocate the extension of the electricity supply on the ground of public health.

Lord Kelvin replied that it certainly was much more healthy than other kinds of light.

In reply to Councillor Kay's question, if we get 90 per cent. of energy from the dynamos, where does the other 10 per cent. go? his **Lordship** said it was all spent in heat; a small part by mechanical friction, the rest by heating on account of electric currents in the armature and in the electromagnets. The best dynamos gave about 90 per cent. of perfect efficiency.

Mr. Shoolbred doubted whether the new dynamo should be one of 300 h.p. He would prefer two, each of 150 h.p., as tending to more economical working.

Lord Kelvin thought that might possibly be true. It would depend on the requirements at the station. His reason for saying one of 300 was that he thought there were enough of small engines at the place for effecting the requisite changes in output. It depends to some degree on the amount of load likely to arise suddenly.

Councillor Kay asked about duplicate armatures for the fresh engines, if they were to choose them of 150 h.p. each.

Lord Kelvin said one duplicate would do for two dynamos of the same size.

Mr. Baynes said he would advise working the 150 h.p. engines up to 200 h.p., which was the usual practice elsewhere: the saving by the additional output would pay for the spare armature referred to by Councillor Kay.

Mr. Shoolbred said that the so-called 150 h.p. engines would give off 200 h.p. each if required.

Lord Kelvin asked what prospect there was of going a good distance from the present works with the supply, say, to two or three miles away.

The **Chairman** said there was a desire to have the light for houses of the better class at Manningham. We have also to buy gas for some of the out districts of the borough. Up to the present, power has not been got for supplying those out districts with gas by the Corporation, and it has been suggested to supply them with electricity. In the plans the committee adopted five years ago, the borough was mapped out into districts so that stations might be provided for any desired quarter. The nearest point of Manningham from the present station was about three quarters of a mile, and the furthest about $1\frac{1}{2}$ miles.

Lord Kelvin said that when the present station is quite filled up another one should be provided for Manningham at some spot where ground was cheap. This would not involve much more cost than having the requisite additional engines, boilers, etc., at the present station. No separate electrical staff would be wanted, but only good engine drivers, stokers, etc. The full capacity of the present station will eventually be taken up by the centre of the town.

Councillor Watson asked if a new station would be wanted if it were decided to supply Manningham, and the **Chairman** said he thought it would be advisable to put one down.

Lord Kelvin said that the nearer the station could be brought to its work, the more economical it would prove. The proposed plan is not the throwing over of the original plan, but only an extension.

Councillor J. Greenwood wanted to know whether if there were a good supply of water at Allerton, and a turbine were put down, the current could be supplied at less than 5d. per unit.

Mr. Baynes said that the present cost of generating electricity by steam, after paying expenses, including interest and sinking fund, was 1·10d. per unit.

Lord Kelvin said that if the water power could be got at a much less cost than that of steam it would then undoubtedly be cheaper. Much expense would also be saved not only in coal, but also in wages of stokers, etc., which would probably knock more than 1d. off the 5d. per unit. His lordship added that with regard to extensions in other districts it would be wise to go on as far as reasonably possible, supplying at first from the present station, and then, when a growing demand has been established, to erect additional stations as found necessary.

Councillor L. Walker asked Lord Kelvin how long he thought the extensions would take to complete them—that is, the extensions now in progress?

Lord Kelvin could not say, as much would depend on the builder and otherwise, but he hoped they would be finished in good time for the winter requirements.

COMPANIES' MEETINGS.

INTERNATIONAL ELECTRIC SUBWAY COMPANY.

The first ordinary general meeting of this Company was held at 72, Bishopsgate-street Within on the 10th inst., Mr. John L. Martin being in the chair.

The Secretary having read the notice convening the meeting,

The **Chairman** said since the statutory meeting held last year, two contracts for supplying the Johnstone system of conduits have been carried out—one for the City of London Electric Lighting Company, Limited, who laid about a quarter of a mile of the conduit in Blackfriars. The types used were the nine way and the six way, each duct or way measuring $2\frac{1}{4}$in. square. It will be readily understood that as this was the first time of laying the conduit in England, it was a most important moment for this Company. It is, therefore, a matter for congratulation that the work done was perfectly satisfactory, the top and bottom troughs exactly fitting together, and when the conduit was keyed up it made a solid structure. It may be mentioned that no skilled

labour is required and no special tools for laying the conduit; in fact, a great deal of the work can be done by boys, and in this way the cost of laying is much less than where separate pipes are used. Each pipe would cost 6d per yard run to lay and joint, whereas 9d per yard run covers the cost of laying and jointing the nine way conduit. Some of the conduit has also been supplied to the Keswick Electric Lighting Company, Limited: their engineer was so pleased with the system that during the last few days he has ordered some more, with handholes for making house connections. During the last month we have obtained the contract for all the electrical mains at Portsmouth. The types used will be a three way and a two way; each duct will measure 2½in. square, and the house connections will be made by means of the handholes, which are a special feature of this system. The amount of the contract is £12,000, exclusive of accessories, and the work will be commenced in about a fortnight's time. It is most important that the system is to be laid in a well known town like Portsmouth, for there its many advantages will be seen and understood in a way which is impossible where only a short piece of work is done. The Company still owns the patents for France, Austria, Belgium, and Italy, as it has not been thought advisable to dispose of these until a large contract has been obtained in England. Negotiations are now being entered into for working some of the foreign patents on a royalty. The Chairman concluded by moving the adoption of the report and statement of accounts.

The motion was seconded and carried unanimously. A cordial vote of thanks was passed to the Directors, and to the managing director, Mr. Margesson, for the zeal he had shown in promoting the interests of the Company, after which the proceedings terminated.

BIRMINGHAM CENTRAL TRAMWAYS COMPANY.

The annual meeting was held on Wednesday at the Queen's Hotel, Birmingham. Mr. J. Ebbsmith (chairman) presided, and the other directors present were Messrs. W. J. Carruthers Wain, M. J. Smith, and W. Weale.

The **Chairman**, in moving the adoption of the report and statement of accounts, said he was sorry to say the Corporation charges, which were referred to last year, had again shown an unpleasant increase; he meant the charges for maintenance of permanent way, and not the charges for rental under the lease. As the meeting were aware, a committee was formed to approach the Corporation on that subject. The Corporation, as they had a perfectly legal right to do, held them to the letter of their bond, and therefore they had to look to an increase of the traffic rather than to any diminution of those charges. In other words, they must spread the average. The question how that should be done was one of very grave anxiety to them all. They were all aware of the view he had taken. He had examined the accounts, and found that upon the steam lines 30 per cent. only of their receipts went into their pockets as working profits, even that being subject to deductions on revenue account. On the other hand, he saw that under the cable working 50 per cent. of the receipts went into their hands as profit. He was also aware of the fact that the steam lines were not uniform. Some were much heavier and more difficult to work than others, and he questioned whether that 30 per cent. must not be largely decreased on certain lines of heavy gradient and traffic. The shareholders would have observed that affairs on the Bristol-road had materially improved during the past year, but they had not improved to the extent which, in his opinion, they were capable of. One of the difficulties they had to encounter was this. They would recollect that two years ago they went to Parliament for certain additional powers with regard to those lines. They were opposed by the telephone company, who required the most stringent provisions to be inserted in that order; provisions which would not only have tied them down with regard to that particular route, but would have tied them down with regard to the whole of the lines in Birmingham outside that route. Reluctantly, therefore, they withdrew the order. Since that time the telephone company had been seeking to put their trammels not merely around them, but all over the country the telephone company had opposed every Tramway Bill and order which had come before Parliament, and ultimately they themselves introduced a Bill making a general law of those special provisions which they had sought to impress upon particular companies. That Bill was referred to a Joint Committee of the two Houses, and was considered by them at very great length with the best scientific information which could be had before them; and the conclusion of that committee had been not merely to lift from the tramway companies generally those restrictions which the telephone company sought to place upon them, but with regard to the particular system adopted on the Bristol road they declared that the telephone company had no *locus standi* whatever. Therefore the Central Tramways Company was encouraged to proceed with the negotiations which had been held in suspense, and which the Board, after careful consideration by the engineers, were encouraged to believe would mean a profit to the Company upon that line of not less than £2,000 per annum. That was a matter of great satisfaction to them.

Mr. Martyn J. Smith seconded the resolution.

Mr. Greenhalgh said he found that from 1891 to 1893 there had been a continual increase in the expenses of management, and he could not see from the balance sheet that there had been any reason why that should be incurred. Take the item of wages—and he was one who liked to see good wages paid where they were deserved—they paid for wages in the unfortunate electrical department in 1891 £2,572 odd. In 1892, without any great increase in the traffic, the amount paid in wages went up by close upon 80 per cent., and this, in spite of the fact, too, that there was only an increase of about 10 miles in the total number of miles run. The gross cost of the general management of the electric trams in 1891 was £5,711, but in 1893, with the same amount of traffic, the expenses ran up enormously.

The **Chairman** pointed out that the Bristol road route was only opened for nine months in 1891 and he thought Mr. Greenhalgh had overlooked that fact in his calculations.

Mr. Greenhalgh replied that that did not affect his contention. The number of miles run in 1891 were practically the same as in 1893, and the cost of the line in 1891 was £5,711, as compared with £9,721 in 1893.

The **Chairman** said Mr. Greenhalgh had rubbed the salt a little deep into the sore which he (the chairman) certainly did feel with regard to the Bristol road line, and his only reply could be that whatever errors had been committed in the past he was doing his best, by effecting economies and alterations, to turn that line into a profit.

The motion for the adoption of the report was then put and carried, with one dissentient. Resolutions were also passed authorising the payment of a 5 per cent. dividend on the guaranteed shares, and of 2½ per cent. on the ordinary stock. The concluding business was the election of directors, upon which the proceedings were a little protracted.

CUBA SUBMARINE TELEGRAPH COMPANY.

The forty fourth ordinary general meeting was held on Wednesday at 58, Old Broad street, under the presidency of Mr. Thomas Greenwood.

In moving the adoption of the report and accounts, the **Chairman** stated that there had been an improvement in the traffic receipts of over £600 as compared with the June half of 1892, while the working expenses had been less by £562. There was, therefore, an improvement in their position of £1,164, which went to swell the balance carried forward to next half year. The reserve made this half year was precisely similar in amount to that made a year ago, but this time it had been divided, £1,500 being transferred to a reserve against any loss that might arise from the failures of banks in which the Company had deposits, and £5,500 being carried to the general reserve fund; whereas a year ago the whole £7,000 was carried to the credit of the reserve fund only. He did not think they would make any great loss by the bank failures; but the half year was sufficiently good to make the provision which he had mentioned. The charge for the annual payment on account of the purchase of the cable laid in 1881 between Cienfuegos and Batabano no longer appeared in the accounts, for the payment had been completed, and the property now belonged to the Company.

The motion was seconded by **Mr. Charles W. Parish**, and was carried unanimously; and dividends were afterwards declared at the rate of 10 per cent. per annum on the preference shares and 8 per cent. on the ordinary shares.

COMPANIES' REPORTS.

ORIENTAL TELEPHONE AND ELECTRIC COMPANY.

Directors: William Addison, Esq. (chairman), B. St. John Ackers, Esq., Henry Grewing, Esq., Thomas Lloyd, Esq., George Bland Frost, Esq. Secretary: Alexr. B. Chalmers, Esq.

Report of the Directors for the year ended December 31, 1892, to be presented at the thirteenth ordinary general meeting of the Company to be held at the Cannon street Hotel, E.C., on Wednesday, August 23, 1893 at 1 p.m.

As mentioned to the shareholders at the last annual general meeting, an appeal was lodged by Mr. Ness against the decision of Mr. Justice Kekewich in the matter of the declaration and distribution of the previous dividend. The Court of Appeal having reversed the judgment of Mr. Justice Kekewich, the Directors had no alternative but to submit the case to the House of Lords for a final interpretation of the agreement with the vendors. The annual meeting has consequently been delayed pending the result of this appeal. Judgment was given by the House of Lords on the 27th ult., which allowed the appeal, and upheld the decision of Mr. Justice Kekewich. The dividends therefore falling to the vendor shareholders have to be paid over to the ordinary shareholders until such time as the arrears of interest due to the latter for the first five years after the incorporation of the Company have been satisfied. These arrears, after payment of the last dividend, amounted to about £13,000. The revenue account for the year shows a balance to credit of £9,085. 5s. 11d., which has been transferred to profit and loss, and including £1,957. 16s. 4d. brought forward from 1891, there remains a balance for disposal of £11,043. 2s. 3d. The Directors propose to deal with this as follows: to write off £251. 13s. 6d. for legal expenses; £77. 10s. 4d., being 50 per cent. of the Company's claim on the liquidators of the New Oriental Bank Corporation in respect of a balance at Mauritius; £533. 15s. 4d. in reduction of capital expenditure; to transfer £2,500 to reserve; and to pay a dividend at the rate of 2½ per cent. on the total paid up capital of the Company, free of income tax, carrying forward £3,191. 10s. 10d. This dividend, together with that declared on the vendors' shares and applied to the ordinary shares, amounts to £3. 12s. 2d. per cent. on all ordinary shares issued prior to February 4, 1886. Although the balance of revenue account

shows but a small improvement over the previous year, there has been a considerable extension of business at every agency, including those of the subsidiary companies. The remittances and dividends, however, received from the East are, with the exception of Egypt, the equivalent of a silver currency, and but for the further decline in the value of that metal during the year, the revenue account would have shown a more favourable result. The Bengal Company has paid a dividend of 6 per cent., and the Bombay Company one of 4 per cent. for the past year, the last named company again applying 10,000 rupees to reserve and depreciation instead of increasing its dividend. Notwithstanding that the directors of the Telephone Company of Egypt report that one of the late officials of that company had been guilty of grave irregularities, they have been able after payment of debenture interest, to distribute the usual dividend of 8 per cent. on the preferred shares, to write off £426 7s. 4d. for depreciation, and to carry forward £1,446. 7s. The China and Japan Telephone Company closed its accounts for the past year with a surplus on revenue account of £519 15s. 7d. after payment of debenture interest; the directors of that company, however, in view of currency contingencies did not recommend a dividend, but applied the amount in part towards the reduction of capital expenditure and depreciation of stores, carrying forward the balance. The Court has finally approved the amendment of the Company's memorandum of association as sanctioned by the shareholders, and the name of the Company is now registered as the Oriental Telephone and Electric Company, Limited. The directors to retire at the present meeting are Messrs. G. B. Frost and B. St. John Ackers, both of whom, being eligible, offer themselves for re-election. The auditors of the Company, Messrs. Deloitte, Dever, Griffiths, and Co., also retire, and offer themselves for re-election.

BUSINESS NOTES.

Burnley.—A search light is to be fixed in some prominent position in the town.

Romford.—The Board of Health object to telephone poles being placed in any part of Romford.

Scarborough.—The general post office is to be connected by telegraph with the South Cliff post office.

Western and Brazilian Telegraph Company.—The receipts for the week ended August 12 were £2,354.

Taunton.—The Town Council have received sanction to borrow £15,000 for the purchase and extension of the electric light works.

Blackpool.—The work of constructing the central station of the Corporation is slowly progressing. Most of the machinery and accessories has, however, arrived.

Bolton.—Tenders are invited by the county borough of Bolton, as will be seen by our advertisement columns, for the supply and fixing of alternating current transformers.

Brush Electrical Engineering Company.—The directors recommend a half-yearly dividend at the rate of 7 per cent. per annum on both the preference and the ordinary shares.

Personal.—The Watch Committee of the Liverpool Town Council have appointed Mr. W. C. P. M'Muldrow as electric inspector for the city, in the place of Mr. Sherman, who has resigned.

Liverpool.—Complete courses of instruction by the University College of Liverpool are arranged in civil, mechanical, and electrical engineering. Further particulars are given in our advertisement pages.

Coatbridge.—The Town Council have adopted a recommendation of the Electric Light Committee to light the Municipal Buildings by electricity supplied by the House-to-House Electricity Company.

City and South London Railway Company.—The receipts for the week ending August 13 were £826, against £721 for the same period last year, or an increase of £105. The total receipts for the second half-year of 1893 show an increase of £390 over those for the corresponding period of 1892.

Edinburgh.—On Monday, at a meeting of the Edinburgh and Leith Gas Commission some discussion took place with regard to the terms on which the Commission would supply gas to the Edinburgh Corporation for driving their electric light plant. It was agreed to treat the Corporation on the same footing with other large consumers.

Gosport.—The Roads and Works Committee of the Gosport and Alverstoke Local Board have recommended, and the Board have adopted, the recommendation that the application of Messrs. Bromwich and Angove, the solicitors to the electric tramway company, for the Board's approval to their application for extension of time be granted.

Spain.—An assistant electrical engineer is required for Madrid by the Electricity Supply Company for Spain, of 15, St. Helen's-place, E.C. Applicants must be able to go out at once. The salary will not exceed £200 per annum, and applicants must have had experience of high-tension alternating current stations. Letters to be sent to the secretary as above.

Dewsbury.—At a meeting on the 10th inst. of the Town Council, a letter was read from the Board of Trade forwarding copy of regulations and conditions for securing the safety of the public and for ensuring a sufficient and proper supply of energy, which the Board propose to make under the Dewsbury electric lighting order. The regulations were approved.

Brechin.—Mr. Jamieson has given notice to the Police Commission that at the next meeting he would move that an electric light installation, sufficient both for the new police office and free library, should be erected at the former, and that the Watching, Lighting, and Fire-engines Committee be empowered to get specifications drawn up by an electrical engineer.

Fleetwood.—At the monthly meeting of the Improvement Commissioners it was decided to permit Messrs. Andrews and Preece, Limited, of Bradford, and Messrs. Greenwood and Batley, of Leeds, to supply complete tenders for electric lighting in the district. The clerk reported that the Board of Trade had extended the limit of time in the Fleetwood Electric Lighting Order, 1890, to October 20, 1893.

S. J. Claye, Limited.—This Company has been registered by Gears, Son, and Pease, with a capital of £100,000 in £10 shares, to acquire as a going concern the business of railway rolling stock manufacturer and coal and coke merchant now carried on by the trustees of the late S. J. Claye at the Manor House Works, Long Eaton, and at Derby, and to carry on business as mechanical and electrical engineers.

Telephone Wires.—Mr. A. Morley, replying to Captain Bagot in the House of Commons stated that the powers to place telephone wires or tubes underground, either in London or other towns, are regulated by statute, and are in all cases subject to the consent of the local authorities, with an appeal in certain cases to a police or stipendiary magistrate or county court judge, and a further appeal to the Railway Commissioners.

Overhead Wires.—In the case of John Hart *v.* the National Telephone Company, which came on for assessment of damages in the County of London Sheriffs' Court, Holborn, the plaintiff recovered £195 compensation for personal injuries sustained through the falling of an overhead wire upon him while driving with his son in York-road, Wandsworth. In a second action, brought by the son, judgment was entered by consent in his favour for £60 and costs.

West Bromwich.—A memorial is being prepared for presentation to the Yardley surveyors seeking for facilities for the placing of the Acock's Green and Yardley districts in communication with the National Telephone Company's system. The project of the establishment of an exchange at Acock's Green was entertained about two years ago, but a number of residents objected, under the impression that it would injure the neighbourhood. A different view is now believed to prevail.

Craiginches Engineering Works.—These new works, which belong to Messrs. Harper, Limited, have just been equipped with the electric light. There are installed 35 arc lamps, energised from a dynamo giving 100 amperes at 260 volts. The dynamo is driven by a large Tangye gas engine, which assists a duplicate engine to drive the main shafting for the whole works. The installation is the largest of the kind in Scotland. It has been erected by Mr. F. Heppert, of London. The offices are also lighted by 35 incandescent lamps.

Bandon.—Mr. C. Crowley (chairman), presiding at the monthly meeting of the Town Commissioners, said that the motion for refusing consent to the granting of a provisional order by the Board of Trade might be passed that day. There was a lot made about the company because he happened to have a share in it. The matter had been submitted to a meeting of the ratepayers, and the majority authorised the Commissioners to negative the proposal, and he did not see why they could not do it that day. Ultimately the matter was adjourned to the next meeting.

The Bankside Station.—Mr. Leoline A. Edward, of 19, Laurence Pountney-lane, E.C., informs us that he has received from the Brush Electrical Engineering Company an order to supply and fix one of his patent circular furnace coking stokers. It is to be applied to a Babcock and Wilcox boiler at the Bankside station of the City of London Electric Lighting Company. It will be somewhat of a novelty in this country, as although many of these stokers have been fitted up on the Continent, not one is yet working here, although scores of them are in use on Lancashire boilers.

Harrogate.—The sub-committee of the Town Council appointed to consider electric lighting recommended at a meeting on Monday that the Council should carry out the electric lighting order, that Mr. Wilkinson should be appointed electrical engineer to the Corporation, and that Mr. Wilkinson should be instructed to work out the details of a scheme on the basis of the report presented to the committee. It had been previously decided to advertise for tenders from companies willing to supply the electric light. A long discussion took place as to whether it would be advisable to hand the matter over to a private company, but the matter was adjourned for a week to a special meeting of the Council.

Yeadon.—The Local Board have considered a scheme for lighting the township by electricity, and which had been submitted by Messrs. Andrews and Preece, Limited, of Bradford. The project comprised the supply of 1,500 8-c.p. lamps, the cost of which, exclusive of land, buildings, and foundations, they put down at £3,500. The members of the Board were favourably impressed with the scheme, and in order that the Board should be first in the field it was resolved to make application to the Board of Trade for a license empowering them to undertake the supply of electricity. It was further resolved to pay a visit to the Morecambe Electric Light Works, which have been fitted up by Messrs. Andrews and Preece.

London Metallurgical Company.—On Tuesday meetings of the creditors and shareholders of the London Metallurgical Company,

Limited, were held before Mr A. S. Culley, official receiver. In November, 1892, the Company promoted the Areas Plating Company, with a capital of £80,000, to acquire the patent for £40,000, and the business was carried on until the property was taken possession of by a debenture holder. The accounts show total liabilities £17,896 (unsecured £11,830), assets £10,900, and a deficiency of £12,896 to the contributors. No resolution was carried at the meeting of the creditors, owing to an equal division of opinion; but the shareholders elected the official receiver to act as liquidator on their behalf.

Two Waters (Herts.).—An electric light installation has been put up at the works of the British Paper Company, Limited, Frogmore Mill, Two Waters. The work has been carried out by the London and Lancashire Electric and General Engineering Company, Limited, of Kingsland-green, Dalston, N.E. The generator consists of a shunt wound, slow speed dynamo, giving about 60 amperes at 65 volts. The dynamo is arranged so that it can be driven either by steam or water power. The lamps, 43 in number, are arranged on four circuits, each of which can be separately controlled from the main switchboard. An arc lamp of 2,000 nominal candle power is fixed in the Beater House, and is intended for use in colour testing at night time.

Telephony at Rotherham.—A meeting of subscribers to the exchange of the National Telephone Company has been held, in consequence of the notice given by the company to increase the rent from £5 to £8 per annum. After discussion, the meeting expressed itself in favour of the present rate, or as an alternative to dispense with the service. A general feeling was manifested in the direction of an improvement of the service, and complaints were made of want of attention at the central and of difficulty in telephoning with Sheffield and outside districts. It was decided to communicate the views of the meeting to the manager. It was announced that there were 126 subscribers to the Rotherham service, and that more than one-third of this number had given their opinion on the proposed charges.

Gas and Electricity at Newport.—The chairman (Mr. E. J. Phillips), of the Newport Gas Company, speaking at the half-yearly meeting on Monday, said that he did not think that the introduction of electric lighting would do any harm to the gas undertaking. The Corporation of Newport had decided to acquire an installation, at a cost of £30,000, but, under the circumstances, he thought the Corporation should have allowed a private company to see if they could make it pay, and not utilise the ratepayers' money on a speculation. The Alexandra Dock Company and the gas company were the largest ratepayers in the town, and they would not gain any advantage from the expenditure. It was proposed to confine the operations for the present to a small area, but all ratepayers outside that area would have to contribute.

Telephony in Glasgow.—The sub-committee on telephones of the Town Council have taken initial steps towards applying for a license for the municipalisation of the telephone. A section of the committee is in favour of a 10-mile radius, so as to include the outlying burghs and a number of other important towns within that area. The district manager of the National Telephone Company has issued a circular stating that the discomfort occasioned to some of the subscribers during the recent change in the system of operating the Glasgow switch-room of the company has been a matter of great regret to the directors. It was only after grave consideration, and at a very heavy expenditure of capital, that the call-wire system was adopted, and the directors believe that when subscribers and operators get accustomed to the system they will find it much superior to anything that has hitherto been in existence in this locality.

Cardiff.—The plan of Mr. Massey was presented on the 10th inst. at a meeting of the Cardiff Lighting Committee. Alderman Jacobs asked whether Mr. Massey could assure the committee that the distances which had been arranged between the public electric lamps were proportioned to give a good light and make the use of electric lighting a success. If the distances were such as those in the City of London it would be successful, but in St. Pancras it was a dismal failure. Mr. Massey said that the average distance between the lamps in St. Mary-street was about 50 yards, and that where the lamps were closest the distance between them was less than the distance between the lamps in Queen Victoria-street in the City of London, which the committee had found to be the best lighted street they had seen anywhere, and that in other streets the greatest distance between any two lamps did not exceed the maximum distance apart of the lamps at St. Pancras, London.

Chelsea v. London Company.—On Wednesday application was made *ex parte* to Mr. Justice Wright in the Chancery Division on behalf of the Chelsea Electric Supply Corporation for an injunction extending over a week restraining the London Electric Supply Corporation from laying any distributing mains for supplying the electric light within the area supplied by the plaintiffs, except in accordance with the terms of an agreement entered into between the two companies in July last. There had been correspondence between the parties, and the defendants having on Friday last justified what they were doing, this action was brought. Mr. Morton, Q.C., who made the application, on being called upon to explain the urgency of the matter, stated that the plaintiffs might be called upon to supply adjoining owners. Mr. Justice Wright granted an injunction over next Wednesday, but intimated that, in case the defendants felt that the order would do them any harm, they could apply to him on the morrow in Chambers to dissolve the injunction.

Bolton.—In connection with the municipal station to be erected in Spa-road, and which was referred to in our last issue, we may mention that Messrs. Hick, Hargreaves, and Co. have been successful in tendering for the boilers. The tenders for the supply of the engines have been considered, and that of Messrs. J. and E. Wood, Victoria Foundry, has been accepted. The engineer (Mr. Rider, M.I.E.E.) has submitted specifications for transformers and underground cables, which have been approved, and tenders for the supply were ordered to be obtained. The engineer has reported upon the tenders for the supply of dynamos and alternators with a tabulated list of such tenders, and the Lighting Committee has accepted that of the Brush Electric Engineering Company. The Gas and Electric Light Committee of the Town Council have recommended the acceptance of the tender of Messrs. John Fowler and Co. (Leeds), Limited, for providing an overhead travelling crane for the electric light engine house at a cost of £337, and that of Messrs. Bryan, Donkin, and Co. for fitting furnaces and boilers in connection with the new works at £285 on certain conditions.

Bradford.—The minutes of the Gas and Electricity Committee of the Town Council were presented at a quarterly meeting on Tuesday. Alderman F. Priestman (chairman of the committee), in moving the reception of the minutes, stated that the sales up to the end of June 30th, 1893, were £4,210, against £3,126, and the gross profit for the half-year was £2,293, against £1,673, whilst the net profit was £625. 16s., against £387. 7s. for the corresponding period. The total expenditure on the electricity works was £62,109, and there was a profit balance on the whole of the working of £915. 12s. 6d. He also included in the motion a recommendation that the necessary work required in the application of the "three-wire" system, at an estimated cost of £2,050, be proceeded with, and that the Council accept the tender of Messrs. Siemens for the supplying and fixing of two engines, with dynamos and two switchboards, for the sum of £3,025. It was absolutely necessary, he said, that they should adopt these extensions, as they had to refuse a very large number of applications. If they had double the amount of electricity to sell, customers would be forthcoming for it. Alderman Morley seconded the motion, which was carried unanimously.

Oil Insulated Mains.—We are informed by Messrs. Johnson and Phillips, of London and Charlton, that they are now able to undertake the laying of cables for the transmission of current at any voltage, and they guarantee the satisfactory working of the same on their oil insulated system and underground mains, which they work under the patents of the late Mr. D. Brooks and themselves. The firm have constructed at their cable wharf special machinery and oil tanks for the manufacture of this class of cable, and as all the work they have done up to the present time has given satisfaction, a very large business in the near future is anticipated. The firm state that this system can no longer be said to be in its experimental stage, as during the extremely bad weather last winter the whole of the distributing mains at Chatham, Rochester, and Strood were laid down on this system. The mains consist of two high-tension feeders running from the station to seven sub-stations placed at various parts of the towns. The energy having been transformed from 2,400 volts to 110 volts, is distributed down both sides of the street by means of low-tension mains also having oil insulation. Cast-iron house service boxes are fixed opposite every other house, and connections are made both to the transformer and houses by flexible lead-covered oil-insulated branch mains. There is also an arc light circuit running from one end of the town to the other. Each section before being finally connected up was severely tested with 5,000-volt alternating current, and although the circuit was frequently broken whilst the dynamo was run at this pressure, the mains did not afterwards show any weakness when tested with a sensitive reflecting galvanometer.

Lighting at Coventry.—On Tuesday, at the quarterly meeting of the Town Council, the report of the Electric Light Committee was presented. The committee recommended: (1) That the Corporation do themselves undertake the supply of electrical energy under the provisional order; (2) that the high-tension alternating transformer system be adopted for private lighting, and that street lighting be not at present undertaken; (3) that the site in Sandy-lane, which Sir Thomas White's trustees are willing to sell, be purchased from them at £350 an acre; (4) that a station be erected there of 150 kilowatt capacity, to supply 4,300 8-c.p. lamps, with mains and transformers suitable for 12,000 similar lamps; (5) that your committee be instructed to carry out the above recommendations, and to employ a consulting engineer to advise them upon the selected specifications and estimates; (6) that your committee be empowered to employ at the proper time an architect to prepare plans and specifications for the necessary buildings, and to obtain tenders for the same; (7) that your committee be instructed to frame and submit to the Council an estimate of the total capital outlay required, for the purpose of an application to the Local Government Board for the necessary borrowing powers. Your committee believe that the amount required will not exceed £15,000. Preceding these recommendations, the committee presented an account of their work, of which the following is a summary: On April 12, 1892, the Council adopted a report whereby the committee was authorised to accept the offer of an eminent firm of electrical engineers to submit, free of cost, a scheme and estimate for the establishment of a central electric light station, and any similar offers by firms of like standing; also to make enquiries in other towns. On August 16, 1892, the report of Mr. A. Bromley Holmes, the engineer consulted by the committee when obtaining the provisional order, was, at the request of the chairman of the committee, referred back to the committee with instructions "to take Mr. Holmes's letters into consideration, and recommend

to the Council a scheme of electric lighting." Mr. Holmes's report contained three main conclusions (1) That, having regard to local circumstances, the Corporation would do wisely to keep the electric lighting of the city in their own hands; (2) that no advantage was to be gained by delay; (3) that, bearing in mind that the committee looked rather more to private lighting than to the lighting of the streets, a low tension direct current system should be adopted, with a generating station at the old baths, or, if possible, near the centre of the city, and that £30,000 would cover the necessary expenditure. With the first of these conclusions the committee entirely agree. With respect to Mr. Holmes's second conclusion, the committee point out that by the terms of the provisional order the mains were to be laid in certain streets within two years of its date, and that in default the Board of Trade may revoke the order. The two years expired on June 11 last, but it is not probable that the Board will take the extreme course of revoking the order if they are satisfied that the Corporation will now proceed to exercise their powers under it with due expedition. No communication has yet been received from the Board on the subject. The committee are of opinion that, while the time devoted to enquiries has been usefully and profitably spent, the time has now come when operations for the lighting of the city should be taken in hand. Mr. Holmes's third conclusion must be considered in connection with the schemes submitted to the committee by various firms and the enquiries made. In submitting these schemes the various firms concerned had an entirely free hand; plans of the city and all other information which they required were furnished to them, and each firm was left to choose its own system and site. In the result three firms (Brush Electrical Engineering Company, Limited, Messrs. S. Z. de Ferranti, Limited, and Messrs. Hammond and Co., all of London) recommended the high tension alternating transformer system, with a station in Sandy lane, near the Cotton Mill; one (Electric Power Storage Company, Limited, London) recommended a high tension direct current system with motor transformers in sub stations and storage batteries, the generating stations to be placed in the Pool Meadow; and two (Electric Construction Corporation, Limited, of Wolverhampton, and Messrs. J. H. Holmes and Co., Newcastle) recommended a low tension direct-current system with or without storage batteries, the generating station being placed in the Pool Meadow. A comparison of the estimates which accompanied these schemes convinced the committee that, light for light, the high tension alternating transformer system involved the smallest capital outlay, and was, especially when the probability of an extension into the residential parts of the city was taken into consideration, the best adapted to the needs of Coventry. This conclusion, though at variance with the recommendation of Mr. Holmes, is in accordance with the opinion formed by the deputation who visited the Crystal Palace. In the meanwhile, Messrs. Siemens Bros. and Co., Limited, asked to be allowed to submit a scheme on the same footing as the other firms. As all the correspondence had been conducted privately, and no information had been allowed to go beyond the members of the committee, the committee considered that the request could be acceded to without injustice. Messrs. Siemens accordingly submitted two alternative schemes, one on the high-tension alternating transformer system, the other on a system combining high tension alternating generation with low tension continuous current distribution. The estimates accompanying these schemes confirmed the committee in their opinion of the greater cheapness of the former system. Alderman Singer (the mayor) moved, and Mr. Fowler seconded, the adoption of the report and recommendations. This was adopted.

PROVISIONAL PATENTS, 1893.

AUGUST 8.

15110. **Improvements in apparatus and devices for starting, stopping, and reversing electromotors.** Frank Alvord Perret, 70, Market-street, Manchester. (Complete specification).

15151. **Improvements in circuit-testing apparatus.** Frederick Sumner Palmer, 24, Southampton buildings, Chancery lane, London. (Complete specification.)

15156. **Improvements relating to telephones.** Parnell Rabbidge, 6, Bream's buildings, Chancery lane, London.

AUGUST 9.

15198. **Improvements in apparatus for obtaining ignition by means of electricity.** Leslie Bradley Miller and Maurice Walter Woods, 2, Gray's inn-road, London.

15217. **Improvements in electric cables.** George Cecil Dymond, 6, Lord street, Liverpool.

15231. **Improvements in electric arc lamps.** Alfred Julius Boult, 323, High Holborn, London. (A. Bureau, Belgium.)

AUGUST 10.

15248. **Improvements in joints for electric light, gas, water, and other similar fittings.** Ernest Alexander Claremont, 53, Arcade chambers, St. Mary's gate, Manchester.

15257. **Improvements in and connected with galvanic batteries.** Siegfried Marcus, 55, Chancery-lane, London. (Complete specification.)

15264. **Improvements in plating metallic surfaces and also prepared surfaces of non-conducting substances by electro-chemical deposition.** Pascal Marino, 24, Queen Victoria-street, London. (Complete specification.)

AUGUST 11.

15284. **An improved safety device for facilitating the replacing or removing of electric fuses.** D. F. Adamson, 76, Sinclair road, Kensington, London.

15322. **Improvements in instruments for telephonic and telegraphic transmission of speech or sounds.** Arthur Thomas Collier, Netria, St. Albans, Hertfordshire.

15337. **Improvements relating to electric arc lamps.** Eugene Daniel Tresel, 18, Buckingham street, Strand, London.

15338. **Improvements in cases for electric bell mechanism.** Louis Bourgeois, 18, Buckingham street, Strand, London.

15343. **Improvements in and relating to the attachment of electric lamps to their posts.** Wilhelm Oexnberg, 151, Strand, London. (Complete specification.)

AUGUST 12.

15355. **An improved electric battery.** Horace Seymour Pyne and Robert Thompson, 24, Highfield-crescent, Rockferry, Chester.

15366. **Improvements in electrical heating and cooking apparatus.** Gustavus Adolphus John Schott, George Adolphus Schott, and George Gustavus Schott, West End Mills, Longside lane, Bradford.

15373. **Electric light fixtures.** Frank W. Davenport, Providence, Rhode Island, United States of America. (Date applied for under Patents, etc., Act 1883, Sec. 103, 16th January, 1893, being date of application in United States. (Complete specification.)

15396. **Improvements in or connected with apparatus for the manufacture of chlorate of potash by electrolysis.** Ferdinand Hurter, 47, Lincoln's inn fields, London.

15406. **A new or improved "cut out" to be employed in connection with electric arc lamps.** William Hopkin Akester and the Akester Electric Syndicate, Limited, 57, Chancery lane, London.

SPECIFICATIONS PUBLISHED

1879.

4903*. **Telephones.** Scribner. (Clark and others.) (Amended specification.)

1890.

9125*. **Telephonic apparatus.** Kingsbury. (Western Electric Company.) (Amended specification.)

1892.

13375. **Electric meters, etc.** Spence.

14061. **Electric current machine and motor.** Aldred.

15066. **Electrical cut-outs.** Webber and Nisbett.

15840. **Electric arc lamps.** Crompton and Pochin.

16571. **Electric motors.** Woodhouse and Rawson United, Limited, and Rawson.

16644. **Measuring electrical currents.** Siemens Bros. and Co., Limited. (Siemens and Halske.)

16805. **Electric search light apparatus.** Scott.

16877. **Telephone signalling apparatus.** Forbes.

16892. **Extracting, separating, etc., metals by electrolysis.** Tommasi.

16893. **Extracting, separating, etc., metals by electrolysis.** Tommasi.

1893.

6975. **Electric circuits.** Berry and Harrison.

8330. **Electric car brakes.** Company.

9302. **Contacts for electric railways.** Prewitt.

9821. **Galvanometers.** Lake. (Whitney Electrical Instrument Company.)

11578. **Electrically welding metals.** Thompson. (Coffin.)

11608. **Electrical heaters.** McElroy.

11609. **Electric switches.** McElroy.

NOTES.

Valence d'Agen.—It is proposed to light this town by electricity, water power to be used.

Tunnel-Lighting.—It is urged that the railway tunnels in and about Paris should be lighted electrically.

Dieppe.—An electric tramway is projected between Dieppe and Arques, with a possible extension to the Arques Forest.

The Corinth Canal.—This canal, which has just been opened to traffic, is lighted at night by means of 70 arc lamps.

Geneva.—It is proposed to hold at Geneva, in 1896, an international electrical exhibition in connection with the Swiss Country Exhibition.

Saint-Leonard.—The Municipal Council of Saint-Léonard (Haute-Vienne) has voted the money necessary for the electric lighting of the town.

Blackpool.—The flagstaff at the Royal Palace grounds has been split by lightning, and in the generating station in the grounds some of the meters were spoiled.

Exhibition.—Steps are being taken by various scientific gentlemen, seconded by financiers, for the holding of an international electrical exhibition in Paris next year.

Chemical Products.—The Société d'Electro-Chimie Soleure has been formed at Soleure, Switzerland, for the purpose of manufacturing chemical products by electricity. Works are to be erected at Luterbach.

Personal.—Mr. B. B. Skirrow, M.A. (Oxon), who has occupied the positions of demonstrator and assistant lecturer in the physics department of Mason College since 1888, has just been elected to the lectureship in physics and electrical engineering at the Manchester Municipal Technical School.

An Electrician Honoured.—As a public acknowledgment of the excellent work and research which Mons. Trouvé, the well-known French electrician, has accomplished in the field of applied electrical science, the "Melsens" prize has been awarded to him by the Société d'Encouragement pour l'Industrie Nationale.

An Electric Yacht.—An electric yacht plying off Southend Pier has been the means of extricating a party of volunteers from an unpleasant position. The volunteers went out on a sailing yacht which got becalmed a mile or two out. The electric yacht proceeded to the rescue, and brought back to shore the party of volunteers.

Manufacture of Steel.—The diamond making experiments conducted by M. Moissan have suggested to M. Jules Garnier a new method of producing steel. The steel is made by placing a bar of iron and a stick of charcoal together in a parallel direction in an electric firebrick furnace of a temperature of 1,000deg., and subjecting them to a strong current. It is claimed that the method is successful.

Leeds.—By neglecting to wear indiarubber gloves when attending to an arc lamp in the goods yard of the Midland Railway at Leeds, Mr. G. Sykes received a shock which resulted in death a few hours subsequently. This is another instance showing the necessity for providing a switch at the bottom of the lamp standard, so that the current, if passing, may be turned off before the lamp is trimmed or otherwise attended to.

An Electric Elevator.—A new type of elevator has been brought out in the United States for use at railway stations and theatres. It is always in operation, and consists of an endless inclined platform, moving at a uniform speed. Passengers step on the platform, and are conveyed from one landing to a higher level. The elevator is driven by an electric motor, and one of the single-file type can transport 3,000 passengers per hour.

Track-Laying under Difficulties.—The Consolidated Electric Railway Company and the local authorities at North Abington, Mass., have had a dispute as to the right of way of the former in a certain street. This resulted in a fight between the townspeople and the Italian navvies engaged in laying the lines of the company. The steamer of the fire brigade was brought on the scene, and a powerful stream of water was thrown on the Italians, thus dispersing them. This is track-laying under serious difficulties.

Blackpool.—It is suggested that the electric cars on the promenade should be overhauled at the close of the present season. The traffic upon the tramway during the past two or three weeks has been very large, and some breakdowns and accidents have occurred. The cars have borne the great strain well, but there have been many evidences that the line itself will need attention when the quiet period comes. It is urged that immediately the season is over the tramway system ought to be put in complete repair, even if the new method of electrical propulsion is not ready for adoption.

Hydraulic Power.—An important scheme for the utilisation of water power is due to M. Ritter, who proposes to tap the River Sarine, near Courtepin, Switzerland. A dam is to be erected, and a portion of the water allowed to pass through a tunnel, and then along a canal to the Milafin fields, where a reservoir is to be constructed. The water would, it is said, yield 10,000 h.p., which would be distributed from Moudon and Estavayer to Morat and Aarberg. It is believed that the utilisation of power would lead to the establishment of many manufacturing works. A provisional committee has already been formed to deal with the matter.

Electric Quackery.—No word is so flagrantly misused as the word "electricity." In country districts, remarks the *Globe*, one has but to mention "electricity" to see a thrill of awe run through one's listeners, and sharp impostors have not been slow to take advantage of this attitude of wondering homage. Every quack who has any rubbish to sell now labels it "electric," and charges heavily for the mystery of the thing, with disastrous results to the villagers. A correspondent of a contemporary tells of a poor woman who presented herself at a hospital with a worthless pair of "electric" spectacles, for which a "gentleman" had made her pay a guinea!

Injunction.—On Wednesday an application was made to Mr. Justice Wright, in the Vacation Court, on behalf of the Chelsea Electricity Supply Company, asking for an injunction restraining the London Electric Supply Corporation from laying or distributing mains for the supply of electric light within a certain radius. The defendants opposed the injunction, one of their grounds being that they were under an agreement to supply the Court Theatre by the 1st September. His Lordship held that the defendants could not lay mains within the stated radius, except if required by the Board of Trade; and as they were not so requested, he granted the injunction asked for until the trial of the action between the companies.

Dunedin.—It seems that there is not at present much probability of the proposed electric tramway at Dunedin being constructed. The Government officer, Dr. Lemon, is of opinion that the double-trolley system is more desirable than the single trolley method. The negotiations in con-

nection with the undertaking have been on the basis of the adoption of the single-trolley system, and Dr. Lemon's view of the matter may prevent the project being carried out. The promoters of the tramway would do well to draw the attention of Dr. Lemon to the experience gained with the double-trolley system at Cincinnati, Ohio, and he will then probably change his opinion as to the advisability of causing the double system to be adopted.

"The Electrical Review." — Our contemporary is ofttimes amusing because it cannot help it. In its last issue there is an attempted witticism about 'bus-lighting; but its meaning is as hard to extract as that of one of Mr. Gladstone's orations. The probability is that a certain amount of space had to be filled, and with the weather so atrociously hot nothing more could be done than to make a guttural chuckle over atrocious puns. Wake up, you dear Old Dutch! you are getting frivolous in your old days. Time was when hitting straight from the shoulder was not uncommon; and, oh! the pity of it, if this gives place to aimless punning. Do you really wish to take up the cudgels on behalf of the paper criticised? If so, go ahead; we are game.

Telegraphy between Kashgar and China.—It is announced that direct communication by telegraph between Kashgar and the interior of China will be established during the present autumn. With the completion of this important line the whole continent of Asia will be traversed by the telegraph, excepting only the region lying between Kashgar and Oscha. When the Russian line connecting these termini is completed—and no objection to the junction has been raised by the Chinese Government—all telegrams from the Far East to Europe are expected to come by this route. Official despatches from the Far East to the British Foreign Office will probably continue to be sent by the present route as well as British mercantile telegrams.

Pocket Telephone. —The Newcastle policemen are reported to have been provided with pocket telephones. As described by one of the local papers, "the apparatus consists of a combined mouthpiece and earpiece, with about a foot or more of wire attached, an affixing pin, and a small key. This apparatus is to be used by the officers in connection with the fire alarms placed at various parts of the city. Instead of breaking the pane of glass in case of a fire occurring in the neighbourhood—as an ordinary individual would have to do—the policeman opens the door with his key, places the affixing pin in a socket provided for it in the lamp, and is in direct communication with the fire brigade." We wonder where the transmitter and battery are situated.

A New Accumulator.—A new type of secondary battery has been devised by M. Hard. A silver wire is kept in a central position by means of a triangular arrangement above and below discs impregnated by the active liquid. To avoid the difficulties inherent to this class of accumulator owing to the pressure of the gas, the upper part of the battery is closed by a hard indiarubber cover in the form of a funnel having a central hole provided with a valve. This valve opens and closes automatically, following the intensity of the pressure of the gas generated. The funnel-shaped cover prevents the escape of the electrolyte in case the battery is overturned. The action of the accumulator is said to be tolerably constant, and it can be used for various purposes.

Measuring the Insulation of Conductors.—An apparatus has been devised by MM. Ducretet and Lejeune for the purposes of measuring insulation resistances in general. It is not submitted as new, but it is considered interesting on account of its practical and portable form, and the large extent of measurements which it permits of being made with precision. The method is as follows: A current is passed from a battery through a fixed resistance (10,000 ohms), which serves as a comparative resistance and through a galvanometer, and the deviation obtained is noted. The current from the same source is then passed through the resistance to be determined and through the galvanometer; this deflection is noted. By calculating that the direct ratio of the intensities is equal to the inverse ratio of the resistances, the result is an equation from which the resistance sought for can be immediately deduced.

Indicating the Position of Trains.—An apparatus for enabling signalmen to ascertain the position of a train on the line has been devised by Prof. Pellat, of the Paris Sorbonne, and is intended to prevent collisions between trains. It consists essentially in the arrangement in the signal-box of a band of travelling paper impregnated with iodide of potassium. A platinum stylus moves over the paper, and when a current of electricity passes through the stylus and paper the iodide is decomposed, leaving a blue mark on the paper, as in the chemical telegraph of Bain. This current is sent by the moving train in the following manner: The wheels press down pedals placed at intervals along the rails, and complete the circuit of a battery connected with the platinum stylus and paper of the apparatus situated in the signal cabin. The marks thus made on the paper indicate the position of the train, and enable the signalman to trace its course along the line.

Traction at Croydon. —Some time ago, as will doubtless be remembered, the Jarman system of accumulator traction was experimentally tried on the Croydon tramways, there being generally two cars in service. The working of the cars was suspended at the termination of six months' operation, and, as Mr. W. J. Carruthers-Wain remarked at a meeting of the Croydon Tramways Company on Tuesday, the Electric Traction Syndicate had not yet been able to renew its running on the line, or to make any definite arrangement in relation to that matter. This particular form of traction was a novelty and extremely beneficial to the traffic. On the other hand, two new motors, which are to be run at the expense of the owners, have been placed on the line for experimental working. One is the Conolly compressed-gas motor, and the other the Lubrig gas motor. The Conolly motor has already been tried on the lines of the Deptford Tramway Company.

Repairing Incandescent Lamps.—A fairly large industry has arisen in the United States in the repairing of Edison incandescent lamps, and it is calculated that no less than 10,000 lamps are repaired daily in that country. Lamps having broken filaments are perforated by crushing the end of the projecting tip of the lamp, and then revolving it rapidly in a lathe whilst the end of the lamp is heated by a gas blast-flame until the glass becomes softened. The centrifugal force, aided by a former placed in the hole, increases the diameter of the latter from one-twentieth of an inch to about three-fourths of an inch. After the remains of the old carbon have been cut away, the interior of the lamp is cleaned by special tools. A new carbon filament is fitted by electroplating of copper at its terminals to minute copper tubes about $\frac{1}{16}$in. diameter and $\frac{3}{8}$in. long. These tubes are inserted in the lamp and secured to the projecting copper and platinum which held the original filament. The next operation is to soften the end of the lamp, and to reduce the orifice to $\frac{1}{4}$in. and seal it to a tube. The lamp is then exhausted and finished in the ordinary way.

Hotel-Lighting.—The last number of a contemporary devoted to the hotel interests contains a long detailed and

illustrated description of the fine mansion at Langlands Bay, near Swansea, which was originally built as a private house by Mr. Crawshay, the well-known South Wales millionaire, but which has been altered and enlarged into a magnificent "caravanserai," principally, of course, for tourists and the usual floating population of a seaside resort. There appears, from the published description, to be a very complete electric equipment of bells and signals in the house, but no mention whatever is made of the presence or lack of electric light throughout the building. Yet one would think that in a summer hotel, of all places, such a method of illumination would be employed, not only to attract a greater number of visitors, but also to secure the best classes. There is room for very considerable development in improved lighting of country and seaside hotels, and it need not be thought in any way essential that a hotel, to be successfully and economically lighted by means of electricity, must be situated in a large town or city.

Humours of the Post Office.—A correspondent addressed to the *Times* a week ago a letter complaining of the humours of the postal telegraph service. He wanted to send a telegram from London on Sunday to the North of England, but he was told that the office was closed. Desiring to have his message forwarded to the nearest office for further transmission, he asked what was the nearest office open. No one could tell him, and there was no map for him to inspect. The official told him that he might see one at Charing Cross, but no. He had to go to St. Martin's, and even there his wishes were not met, and so forth. Then there was the question of the money deposit to cover all possible porterage. This is sad indeed. Of course other correspondents have come forward with similar and other tales as to the eccentricities of the Post Office; but what do they want? The world got along before the telegraphs and before the introduction of railways and steamships, and it can get along without the trouble of Sunday telegraphy. Some people are never satisfied; they want the millennium at once.

The Telephone on Railroads.—The Pennsylvania Railroad Company has adopted long-distance telephones for communication between the leading executive offices of the company. They will, it is calculated, save much valuable time and will aid in the more rapid transaction of urgent business. The important points on the Pennsylvania system thus connected with Philadelphia are New York, Jersey City, Wilmington, Baltimore, Washington, Harrisburg, Altoona, Chicago, and St. Louis. The wires in these and other cities will run into the private offices of the higher officials, for whose exclusive use in the transaction of the company's business the system is intended. No one will be allowed to use the telephones except these officers, even though communication with an official is desired. The telegraph, with all its advantages over former methods, did not ensure absolute confidence between officials, because the message passed through the hands of two and sometimes three or four operators. Consequently, under such conditions, important questions could only be settled after a personal meeting between the officials, and this necessitated a large amount of travelling. Much valuable time will now be saved and business transacted in quicker time.

Water Power.—The utilisation of water power has been undertaken at Tampa (Fla.) by the erection of a dam across the Hillsborough River, six miles from Tampa. This dam gives a 14ft. head of water, which is used to operate six Leffel turbines, varying from 175 h.p. to 250 h.p. each, and which can develop about 1,100 h.p. Only two or three of the turbines are at present being used. One drives a Thomson-Houston generator which is supplying a 2,000-volt lighting circuit, on which Thomson-Houston transformers from 2,000 to 50 volts are used. A second is used on a Thomson-Houston generator which supplies a 500-volt street railway and power circuit. The company doing the work is known as the Consumers' Electric Light and Street Railway Company. They have about five miles of line laid in the city, and are operating four tramcars and one double-decked car. They have four trailers, which can be attached to the motor cars when desired. The current runs from the power-house to Tampa, a distance of six miles, bare copper wires being used to convey the current this distance. The track is being extended to Port Tampa City, nine miles south west; then it is to run six miles north-east to the power-house, making a 15-mile aerial line.

Sparking at Commutators.—The study of the avoidance of sparking at commutators seems to be very much to the fore in technical papers at the present moment, and rightly enough so, if we can get to any good results. Following Mr. Sayer's contribution to the subject, M. Rechniewski has written some practical papers which we are giving in our other columns. In *L'Electricien* last week still another writer, M. J. Staner, takes up the pen to clear the matter in an article on "The Lead of Brushes in Continuous-Current Dynamos." On open circuit, says the author, the brushes will be on the neutral line. At what position should they be set when the current is flowing? He answers this question in detail, and works out his conclusion mathematically. We will content ourselves by giving the result to which he arrives: "In conclusion, we can suppose in practice the brushes to be on the neutral line, and admit, as demonstrated, that the angle of lead is practically proportional to the square root of the armature current." This rule may be useful to the attendants of large dynamos, though we suppose, as before, they will in ordinary cases set the brushes by trial on the position of least sparking. The researches of Rechniewski on means of extending the allowable change of load for the normal position of brushes without sparking, by considering the interior construction of the dynamo, would seem to appeal far more strongly than the mere production of a formula to the instincts of electrical engineers.

Submarine Mines.—By the invitation of Major Knight and other officers of the Mersey Volunteer Submarine Miners, a large party of ladies and gentlemen embarked last week on the War Office steamer "Lord Heathfield," and were taken down the River Mersey to a point about half a mile beyond Perch Rock Battery. The first experiment was very striking. A circuit-closing apparatus, which outwardly resembles an ordinary mooring buoy, was fixed at a certain point in the water, so arranged that the bow of the "Lord Heathfield" should "bump" against this, and cause the first explosion. Immediately the steamer touched the circuit closer, a current was sent along a submarine wire to a special room at the Perch Rock Battery, setting in action a relay, from which the current passed to an exploder attached to a charge of 100lb. of gun-cotton, enclosed in an indiarubber bag, with a wooden frame, and suspended several feet beneath a barrel floating on the water, about 200 yards from the "Lord Heathfield," and half a mile from the battery. The explosion took place instantaneously, the barrel was blown into a thousand fragments and the water rose to a great height. Four or five other charges were similarly exploded in the usual fashion by means of a key. The mechanism inside the circuit-closing apparatus has not yet been disclosed. Of course, the buoys would contain explosives in time of war; and Liverpool may, in such an untoward event, feel tolerably secure from invaders by sea.

Penn'orths of Electric Light.—Electricity, it is admitted, has been driving out of use to a large and increasing extent the use of gas in our clubs, mansions, warehouses, and other large buildings, and the faces of a good many shareholders in gas companies have lengthened in consequence. Mr. George Livesey, the chairman of the South Metropolitan Gas Company, comes to the rescue, however, and, like the Midland Railway, caters for the lower classes when the highest becomes unprofitable. Not contented with supplying the majority of shops and middle-class houses, he now aims at affording a chance to the workers of burning gas in their cottages instead of oil. This is done by means of a "penny-in-the-slot" arrangement, the meter being so arranged that a quantity of about 26 or 27 cubic feet is allowed to pass on the insertion of a penny in the usual slot. This, of course, is sufficient for about six hours' lighting of a single jet, and therefore the cost for an evening's light need be no more than 1d. The fittings, of course, are supplied—working-men cannot afford to purchase these; but otherwise great readiness has been shown in the adoption of gas instead of oil. That there is room for the venture seems proved by the fact that not much more than one-third of the total number of householders in the South Metropolitan Company's district is supplied with gas, and this is not due to the competition of electric lighting, as no supply of the latter is available to any great extent. If "penny-in-the-slot" gas is found to be a boon, why, it may be asked, may we not have pennyworths of electricity? From a technical point of view, there is no objection whatever, but the trouble is in supplying the fixtures and making the necessary connections. As soon as the owners of property can be brought to see the advantages of wiring or connecting houses in readiness for a supply, then, of course, the chief stumbling-block will be removed; but this is looking a long way ahead. At 6d. a unit, a "penn'orth of electricity" ought to be enough to keep a 10-c.p. lamp alight for five hours.

Hearing and Seeing.—Paragraphs have been going the round of the press to the effect that the principle of hearing and seeing by electricity is the same, and this under the authority of Prof. Bell, who is stated to say that all we require to see by electricity is a diaphragm as sensitive to light vibrations as the one now used is to sound vibrations. Prof. Bell is stated to have further said: "Morse taught the world years ago to write at a distance by electricity. The telephone enables us to talk at a distance by electricity, and now scientists are agreed that there is no theoretical reason why the well-known principles of light should not be applied in the same way that the principles of sound have been applied in the telephone, and thus allow us to see at a distance by electricity. It is some 10 years since the scientific papers of the world were greatly exercised over a report that I had filed at the Smithsonian Institution a sealed packet supposed to contain a method of doing this very thing—that is, transmit the vision of persons and things from one point of the earth to another. As a matter of fact, there was no truth in the report, but it resulted in stirring up a dozen scientific men of eminence to come out with statements that they, too, had discovered various methods of seeing by electricity. That shows, what I know to be the case, that men are working at this great problem in many laboratories, and I firmly believe it will be solved one day." This is all very pretty, and, so far as vibrations are concerned, has been said before, but in these general statements too little explanation is given, and that misleading. Sound vibrations are wholly due to the vibrations of ponderable matter, light vibrations are the vibrations of imponderable matter—or what we have always been told is imponderable—the hypothetical ether. These latter vibrations do affect ponderable matter, as is proved by our own eyes. Again, electrical phenomena are supposed to be due also to some action upon the ether. In telephony the sound waves first act upon the diaphragm and cause it to vibrate. These vibrations influence the etheric electrical action; this action is propagated to a distance, and in its turn influences a second diaphragm. Suppose we could get a diaphragm sensitive to light vibrations, would that enable us to see by electricity in like manner as we hear at a distance by the aid of electricity? Most emphatically, no; and most emphatically, the principle involved is not the same, Prof. Bell notwithstanding. We do not see by means of direct, but by means of reflected light, which makes all the difference to electric "seeing."

A Large Search-Light.—What is classed as the largest and most powerful search light in the world has just been completed by the United States General Electric Company, and is now being erected at the Chicago Exhibition. It stands about 10ft. 6in. high to the upper side of the ventilator on the top of the drum, and the total weight is about $2\frac{3}{4}$ tons, but so perfectly is it mounted and balanced that a child can move it in any direction. The reflecting lens mirror used in this projector is 60in. in diameter. It is a concave spherical mirror of the Mangin type, free from spherical aberration, reflecting a sensibly parallel beam of light. It was manufactured especially for this projector in Paris, France, and is a most perfect specimen of optical work, $3\frac{1}{4}$in. thick at the edges and $\frac{1}{16}$in. thick at the centre, and weighs about 7cwt. The metal ring in which it is mounted weighs about 7cwt., and the total lens, ring, and cover weigh about 15cwt. This great mirror is mounted at one end of the big drum, the outer end of which is furnished with a door consisting of a metal rim in which are fixed a number of plate-glass strips $\frac{5}{16}$in. thick by 6in. wide. Inside this drum, and sliding upon ways arranged on the bottom, is placed the electric lamp, the source of the light which is reflected by the mirror. It is entirely automatic in its action, is 6ft. high, and weighs about 400lb. The carbons used are also made especially for it. The upper or positive carbon is $1\frac{1}{4}$in. in diameter and $22\frac{1}{2}$in. long, with a $\frac{5}{16}$in. core of soft carbon running from end to end through its centre. The lower or negative carbon is $1\frac{1}{4}$in. in diameter, is 15in. long, and also has a core of soft carbon running through its centre. In addition, its outer surface is heavily coated with copper. The positive carbon is set a little in front of the negative, and thus almost all the intense light of the incandescent crater is cast upon the reflector. The maximum current at which this lamp operates is 200 amperes, and at this current the lamp has a luminous intensity of about 90,000 to 100,000 candles, and the reflected beam is said to have a total luminous intensity of about 375,000,000 candles. Ventilators at the top and sides allow a constant current of air to pass through the drum and dissipate the heat generated by the arc lamp; and they are so arranged that no light can escape through them. All the connections for adjusting the positions of the carbons and the lamp are brought through the drum to the outside, and are arranged in close proximity to one another at one side, so that all may be manipulated by the operator without moving from his position. Through openings in the drum covered by densely-coloured glass the operation of the lamp may be watched and its adjustments verified. The drum is supported by trunnions in bearings at the top of a Y-shaped fork, set in a base-plate, and the whole is supported on a system of friction wheels, forming a turntable resting upon

the top of a massive pedestal supporting the whole structure. The drum, fork, and base-plate may be rotated horizontally on the turntable either by hand or by gearing provided for this purpose. The drum may also be raised or lowered in a vertical plane.

The Edison Lamp Patent.—It seems that a decision of the United States Supreme Court alone will definitely fix the date of expiration of the Edison lamp patent. The *Electrical World* of New York has collected various facts bearing on the matter, and in commenting on it says: "Of the three main legal points not yet settled by a final decision of that court, two are given little weight. A third one, however, in regard to whether the date of application or the date of issue of an American patent shall prevail in determining priority of date with reference to foreign patents, rests upon a more debatable basis, notwithstanding the unanimity of the lower United States courts in deciding in favour of the date of issue. The first point of law is as to whether the life of an American patent issued subsequent to a foreign patent will be limited by the life of the foreign patent if the patentee is an American citizen. This has been decided in the lower United States courts in the affirmative, and no weight seems to be attached to the negative contention. The second point of law is in regard to which of the three dates on the English patent, which expires November 10, 1893, shall prevail. There have been several decisions on this question, and all have been in favour of one or the other of two dates. Both of these, in the case of the Edison patent, are subsequent to the American date of issue, and therefore do not affect the American life of the patent. Owing, however, to the Edison patent attorneys in an endorsement on the American patent wrongly designating November 10, 1879, as the date of the English patent, which is previous to the date of the American patent January 27, 1880), it may be contended in court that the date thus given should hold and consequently the American patent expire with the English one on November 10, 1893. It is not thought, however, that there is any hope of maintaining this point, particularly as a court has declared the endorsement in question void, the Commissioner of Patents having exceeded his authority in admitting it. The third point, to which we referred first, has strong equities in favour of the date of application, besides one or more points of law. Those who hold this view contend that it is unjust that the American patentee should have his home patent limited in life by a foreign patent because a foreign patent office has been more expeditious than the American one. The applicant has absolutely no control over the date of issue in any case, and should the English patent issue prior to the American one, the life of the latter is only 14 years, instead of 17 when the American patent is first issued. As in all foreign patent offices the time is almost always less between the date of application and the date of issue, the effect of the law, as interpreted by the lower courts, is to deny a patentee a life of 17 years to his domestic patent if he should also take out foreign patents—a state of affairs surely never contemplated by the framers of the statute thus construed. Notwithstanding that all of the decisions of the lower United States courts have been against accepting the date of application, it is held by many that if the same courts were not bound by their previous decisions they would decide differently at the present time; this, it is asserted, has been indicated by expressions from the bench and by the fact that the United States Supreme Court has reversed the lower courts in other questions of law under the same statute. While it is thus not at all certain that the Edison patent will expire with the Canadian patent on November 19, 1894, yet the chances that the United States Supreme Court will overrule the point of law repeatedly and unanimously affirmed by the lower courts has the odds largely against it."

Lighthouse Illuminants.—In view of the facts adduced by authors in papers read before the recent meeting of the International Maritime Congress in the metropolis, and which have been reproduced in these columns, the following statements will doubtless cause considerable surprise among many maritime people. The remarks have been published in a provincial daily paper, and from which we quote as follows: "Captain J. T. Bragg, R.N.R., adviser to the Liverpool Steamship Owners' Association, which represents the Cunard, White Star, and other lines, says: 'In my opinion, based upon nearly 14 years' experience in the Transatlantic passenger trade, the adoption of such a light as the "Giant Lens Lighthouse Gas-light," and a powerful fog syren on the Old Head of Kinsale, would materially increase the safety of the navigation to the mail steamers and other vessels which have to make Queenstown a port of call. An electric light of the same power and brilliancy would not show so far in hazy weather, as from its colour being more nearly assimilated with that of the fog it is more readily blurred out, whilst the gas flame, being of a different colour to the fog, would more readily be seen at the same distance. In confirmation of the above, when I was in command of the ss. "Anterior," bound round from London to Liverpool, at night, at a short distance east of Lizard Point a fog came on; as we approached the point we heard the sound of the Lizard fog syren. The two lights on the Lizard are powerful electric lights, which we were anxiously on the look-out for, but we were unable to see them, as they were completely obscured by the fog, whilst we were well within the sound of the fog syren, and only passing at a safe distance outside the dangers lying off the point.' Captain N. N. Digman, of the ss. 'Tempo,' says: 'The electric light is a bad light to see in hazy or foggy weather; far worse than an oil or gas light.' Captain T. Thomson, R.M.S. 'Munster,' remarks: 'I am sure the new light will pierce fog far better than the electric light. I have seen a great deal of the latter light at Holyhead, and consider it a very poor light for foggy weather.' Captain Wm. Dane, ss. 'Sinloo,' Newcastle, says: 'I have many times passed the new electric light at St. Catherine's Point. It is no doubt a very bright light, but in my opinion it is much too bright and dazzling, which makes it difficult to find out a ship's true position. In fog it is soon obscured.' Captain Boyd, of the ss. 'Countess of Dublin,' observes: 'I have often passed quite close to the electric lights on the south coast of England in hazy weather and found them invisible. In fact, to my mind, as a lighthouse light the electric light is quite useless.' Captain J. Henderson, secretary British Shipmasters' and Officers' Society, puts his views in these terms: 'I am of the same opinion as I have ever been—that the electric light for lighthouse purposes is a delusion and a fraud on the sailor. I nearly lost my life on Dungeness Point when the electric light was put there. The Trinity House yacht, "Captain Wallace," got on shore there—so much for electricity.'" These statements differ from the results obtained by Mr. Stevenson mentioned in our last issue, and also from the experience gained in the electric lighting of lighthouses in France as referred to by M. Blondel and M. Bourdelles. In fact, it has been shown that in all weathers and at all distances the penetration of the electric light has proved to be superior to either gas or oil lights; and in face of this it is difficult to understand the statements quoted above.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC.MEM.INST. ELECTRICAL ENGINEERS.

INCANDESCENT LIGHTING.

(Continued from page 127.)

Analysing this table, it may be remarked that lamps of type A take extremely small initial power—only 1·5 watts per candle-power, but their life is soon ended—only lasting 45 hours. Independent of the terrible heavy cost of lamp renewals, the trouble and labour involved in the renewals would prohibit their use. Consider the work to be done in a building having, say, 1,000 lamps. A fresh lamp would have to be put in somewhere every three minutes. The mean watts per candle-power is certainly lower than what is required for a lamp of type E, and there is hence a saving of cost of power; but an E lamp has 1,000 hours' life, and 22 lamps of the A type would have to be bought in order to get the same hours of burning as one lamp of the E type. Lamps used at this rate will soon bring up the expenses and swamp the saving that is effected by the small consumption of energy. Furthermore, type E after burning 1,000 hours will still give a good light of 12·5 c.p., while absorbing the same energy as at the start—namely, 54 watts; but a lamp of type A after burning 45 hours only gives 5·6 c.p.—a light so poor that if the lamp were not at the end of its life it would not be worth while using it. An E lamp at the end of its life of 1,000 hours consumes only 23 per cent. more power per candle-power than at the commencement of its life, whereas an A lamp at the end of its life of 45 hours consumes 143 per cent. more power per candle-power than at its commencement, the increase being more than six times as much. These figures show how extremely rapidly the A lamps deteriorate, and that it is only in the early stage of their life that they can claim to be efficient and economical in the true sense.

Having discussed the question of efficiency of lamps, so far as the maker is concerned, we must now go further, and find out the efficiency of the lamp from the consumers' point of view, otherwise that of £. s. d. The actual running cost of an incandescent lamp may be composed of two factors, as follows: (1) The cost of lamp renewals; (2) the cost of energy consumed.

The first factor depends on the life of the lamp, and the shorter this is the more will the cost be for lamp renewals. The second factor depends on the maker's efficiency, or the mean watts consumed per candle-power, and also on the price of electricity. The cost of lamps of, say, 16 c.p. may be taken as fixed, and in view of the expiration of lamp patents in November, we may put down the cost of a lamp at 2s., this price being the same for all lamps of 16 c.p., whatever their efficiency and whatever their life may be.

The price of electric energy will vary according—some places it is only 5d. per unit, at others as much as 1s. per unit is charged. When electricity is generated in private establishments, such as in factories, the cost of production is very low, and may be put down at, say, 2d. per unit, so the running cost will be calculated over a range of from 2d. to 1s. per unit. From this it is easy to see that the price of electricity has a good deal to do in deciding how to run the lamp, because when the cost of supply is high, it may be best to slightly overrun the lamp. On the other hand, when the cost of supply is low, they can be run slightly under the normal pressure. This latter case particularly applies to private supply, such as a large factory, where the cost of generating electricity is extremely low.

Tabulation 27 shows the total running cost per candle-power hour of the five types of lamps given in Tabulation 26, calculated out for prices from 2d. to 1s. per unit, and based on Siemens and Halske's data in Tabulation 26.

In the case of type A, which takes an initial consumption of 1·5 watts per candle-power, the cost of lamp renewals is nearly twice as much as the cost of electric energy, even when at 1s. per unit, the exact figures being:

lamp renewals = ·0626, energy = ·0342; total = ·0968.

TABULATION 27.

Price of supply unit in pence.	Total cost of 1 c.p. per hour in pence.				
	A.	B.	C.	D.	E.
2	·0683	·0207	[illegible]	·0100	·0093
3	·0711	·0244	·0180	·0141	·0132
4	·0740	·0281	·0222	·0181	·0170
5	·0768	·0318	·0264	·0222	·0209
6	·0797	·0355	·0307	·0262	·0247
7	·0825	·0392	·0352	·0302	·0286
8	·0854	·0429	·0391	·0342	·0324
9	·0882	·0466	·0433	·0383	·0363
10	·0911	·0503	·0475	·0424	·0401
11	·0939	·0539	·0517	·0464	·0440
12	·0968	·0576	·0559	·0504	·0478

With type B, taking 2·0 watts initially, the two components nearly balance when the price is 4d.; then

lamp renewals = ·0134, energy = ·0147; total = ·0281.

With type C, taking 2·5 watts initially, we have at the lowest price, 2d.,

lamp renewals = ·00544, energy = ·00842; total = ·0138.

With type D, taking 3·0 watts initially, we have at same price,

lamp renewals = ·00201, energy = ·00808; total = ·01.

With type E, taking 3·5 watts initially and at same same price of 2d.,

lamp renewals = ·00166, energy = ·0077; total = ·00936.

In all the above cases the lamp renewals remain constant throughout the range of prices per unit, and even when 1s. per unit is charged, type E costs less than one-half of type A.

When a lamp reaches the end of its life its filament breaks, and so the light ceases, because the circuit is broken. Upon examining these spent lamps, it will be observed that the filament nearly always breaks from about ¼in. to ½in. below one of the platinum joints, occasionally they will break just before the bend; the slightest fracture of the glass bulb of the lamp will lead to the destruction of the filament on account of air getting inside. One brake horse-power will run about 10 lamps of 16 c.p., and one kilowatt of electric energy will run 15 lamps at least, possibly 16.

Incandescent lamps are run in parallel at a constant pressure, the current increasing or decreasing according as the lamps in use increase or decrease. For example, if there be 50 lamps of 16 c.p. in use, worked at a pressure of 100 volts, they would probably take a current of about ·6 ampere each, or a total of 30 amperes, and this gives a consumption of 3,000 watts of electrical energy. Increase the number of lamps to 100: the current taken will now be 60 amperes, and the electrical energy 6,000 watts, the lamps being in parallel. When the number is doubled there are double the number of paths for the current to traverse, consequently the total resistance of the circuit is halved, and since the pressure remains constant, therefore, by Ohm's law, the current becomes doubled. The greater the number of lamps the greater the current, and hence the greater the section of the mains.

The resistance of carbon decreases as the temperature rises, which is the exact opposite action of metals. This decrease is only very little for every degree C. increase of temperature, and the resistance of the filament of an incandescent lamp when alight is five-sixths the resistance when cold, so that in calculating the electrical energy consumed by a lamp, its resistance when hot must be taken. The resistance of a lamp of 16 c.p. when alight, and worked at a pressure of 100 volts, is about 160 ohms, and when cold, or not alight, it is about 190 ohms. The following data concerning the filaments of various lamps may prove interesting, all being worked at 105 volts pressure. The diameter is a little less than what it would be when the lamp was new, owing to its disintegration:

100 c.p. .... length, 28·6 cm., diameter, ·0635 cm.
50 c.p. .... length, 26·0 cm., diameter, ·037 cm.
16 c.p. .... length, 23·0 cm., diameter, ·013 cm.

When electric power is distributed over wide areas from

one central source it is impossible to have the same potential difference everywhere, so that lamps that are situated near the source must inevitably be run at a greater pressure than those at the farther points. The Board of Trade allow a variation of 4 per cent of the working pressure, so that there is a margin of 8 per cent. altogether, since the variation may be 4 per cent. below normal pressure or 4 per cent above normal pressure. If the normal pressure is produced at a point or zone midway between the source of generation and the farthest point supplied, then a 16 c.p. lamp placed near the source will give about 20 c.p., and when placed at the farthest point, only about 12 c.p.; this is when full advantage is taken of having the pressure at the source 4 per cent. too high, and at the farthest point 4 per cent. too low. Evidently the increase of candle-power is accompanied with a short life, and the decrease of candle-power with a long life. This maximum variation of pressure occurs when the maximum number of lamps are burning—that is, when the current in the distributing mains is at its greatest; and as the current decreases and the number of lamps alight decreases, so the variation of pressure will decrease and approach nearer the normal pressure.

(To be continued.)

MEANS OF DIMINISHING SPARKING IN CONTINUOUS-CURRENT DYNAMOS.*

BY W. C. RECHNIEWSKI.

(Continued from page 159.)

Influence of the Winding.—The choice of a winding is not unimportant from the point of view of the sparking, and it is this latter consideration which ought to be most regarded; for from the point of view of production of energy all windings are much alike.

Let us consider first of all the two-pole dynamos. For these we have the choice between drum winding and ring winding.

I have already proposed to consider the propensity to sparking as proportional to the change of the flux traversing the short-circuited coils, when the current varies by a determined fraction of the current, c_n, of the section—for instance, when the current is reversed and taken from c_n to $-c_n$. Let us compare the two windings.

Let F be the normal magnetic flux of the dynamo, N the number of sections on the armature, n the number of turns per section with drum winding.

In small machines in general the mechanical considerations limit the number of segments of the commutator, and consequently the sections in the armature. We will suppose the same number of sections for the two windings. Let C be the current at the moment considered. Then, in these conditions, it will be noticed first that one turn encloses the complete flux, F, in the case of the drum winding, and the flux $\frac{F}{2}$ in the case of the ring armature, and that the number of turns per section is twice as large for the ring as for the drum winding.

When the current changes suddenly its direction in the section under the brushes, that is, passes from $\frac{C}{2}$ to $-\frac{C}{2}$, the changes of flux traversing the circuit is, for drum winding:

$$\alpha \,.\, F \,.\, C \,.\, n^2,$$

where α is a factor dependent on the form of the characteristic at the point considered. Exactly, α is equal to the length of the sub-tangent expressed in ampere-turns, and taken on the characteristic at the point where the machine is working normally. It is easy to take off this value on the characteristic given for any machine.

For ring winding we shall have for the same expression—

$$\alpha \,.\, \frac{F}{2} \,.\, C \,.\, (2\,n)^2 = 2\,\alpha\,F\,C\,n^2,$$

the number of turns per section being twice as many. We see, therefore, that, all other things being equal, the propensity to sparking is twice as great for ring armatures as for drum armatures at equal size of sections of the commutator—*i.e.*, for small machines.

When the size of the dynamos increases, the contrary occurs; it happens, indeed, at the position when only one turn per section is used, and if the size of the dynamo, and consequently the magnetic flux, increases still more, the number of sections must be diminished.

For electrolytic dynamos giving 20 to 30 volts we very rapidly reach this state, even for machines of low power. Here it is the voltage desired which determines the number of sections, and not mechanical considerations, and we see that for the same voltage we shall have twice as many sections for ring winding as with the drum winding; and for the variation of current from $\frac{C}{2}$ to $-\frac{C}{2}$ in the section under the brushes the variation of flux in its current will be:

For drum armatures, $\alpha\,F\,C$,

and for ring armatures, $\alpha\,\frac{F}{2}\,C$.

The propensity to sparking will thus be only half as great for ring as for drum winding.

For large two-pole machines the considerations of voltage limit the number of sections in the armature; ring winding will be preferable because it gives twice the number of sections.

We will now consider four-pole machines. We have here the choice of several windings:

1. Simple ring winding with poles connected in parallel with four brushes at the commutator; or else two brushes only and a connector.
2. Ring winding in series—*i.e.*, connecting in series the sections placed similarly under poles of the same name. This winding can be employed without connector (Fritsche system).
3. Drum winding with the poles in parallel (Thury).
4. Drum winding in series (Fritsche, Thomson, etc.).

As for the two pole machines, we have here also to distinguish several cases. In the first place, the small machines with several turns per section, and the large machines with only one turn per section, the number of sections being limited by the voltage required.

The propensity to sparking—*i.e.*, the change of flux traversing the circuit of a short-circuited section when the current changes direction—is in the first case:

For drum winding with poles in parallel, C being the current passing through armature, n the number of turns per section, and F the flux on each pole:

$$\alpha\,F.\,\frac{C}{2}\,n^2.$$

With the winding in series, there are twice as many turns per section, but each section will enclose a double flux, and the current which circulates therein will be twice as strong, therefore we shall have

$$\alpha\,2\,F\,.\,C\,.\left(\frac{n}{2}\right)^2 = \alpha\,F\,\frac{C}{2}\,n^2.$$

From the sparking point of view it will therefore appear that these two windings are equal.

For the ring armature we shall have twice as many turns per section. The propensity to sparking will be therefore expressed by the expression:

$$\alpha\,F\,C\,n^2.$$

Both for winding in series and in parallel, the sparking propensity in the ring will thus be twice as great as for drum winding.

For large dynamos where only one turn per section can be used we shall have twice as many sections in the ring armature as for the drum, and twice as much for parallel winding as for series winding.

To bring all this into practical shape, I have calculated for various dynamos built by M. Postel-Vinay; and the numerical values given by the formula coming out remarkably well, I have found by determining for each machine α, according to the characteristic:

For a dynamo of 100 volts and 10 amperes, with a flux

* From *L'Electricien.*

of 640,000 and nine turns per section, drum winding, and a = 4,000:

129,600.

For a dynamo of 8,800 watts, 110 volts with F = 2,700,000, two turns per section, drum winding, and a = 8,000:

108,000.

For a dynamo of 20,000 watts, 120 volts, F = 5,000,000, one turn per section, drum winding, and a = 12,000:

75,000.

For a dynamo of 30,000 watts, four poles, 120 volts, F = 5,000,000 per field magnet, one turn per section, drum winding, poles in parallel, and a = 10,000:

68,000.

These figures are very low; usually they are much higher. But it is to be noticed that these figures are all of the same order; they vary much less amongst each other than the power of the dynamos. The highest figure is for the small dynamos of 1,100 watts, and as a matter of fact it was this machine whose regulation was most delicate; while for the large machines of 20,000 watts a change of load to the extent of 50 per cent. could be made without causing sparking.

(To be continued.)

WESTINGHOUSE ARMATURES.

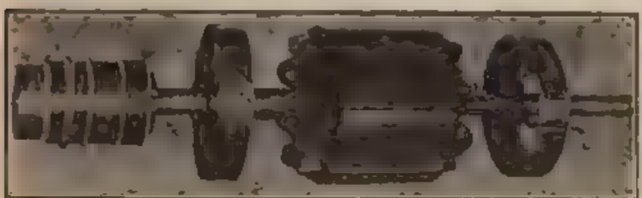
We gave last week a general description of some of the best-known forms of Westinghouse dynamos. We wish to supplement that article by a more detailed description of the Westinghouse armatures.

The armature of a dynamo is a complicated piece of machinery. Composed of thin plates of iron, strips of insulated copper, layers of mica and bronze commutator segments all kneaded, as it were, together, and often held by curious devices of clamping rather than real mechanical arrangements, the ordinary armature has been not inaptly compared to "a bundle of wires on a stick." To overcome these engineering ineptitudes has long been the endeavour of electrical designers, and not the least successful in this direction have been the Westinghouse Company, whose very mechanically-built armatures we illustrate in several different types.

The general aim in these armatures has been to secure (1) solid driving of the coils, (2) that the coils should be lathe-wound beforehand, and (3) that the armatures shall be smooth faced, with no wire capable of injury on the outside; at the same time they are so arranged as to enable any damaged coil to be quickly taken out and replaced without the necessity of changing the whole armature.

Alternate Current Armature.

Alternate-current generators are constructed in which the fields are excited in part from separate exciters and in part by current from the dynamo itself. They are also



Westinghouse Toothed Armature.

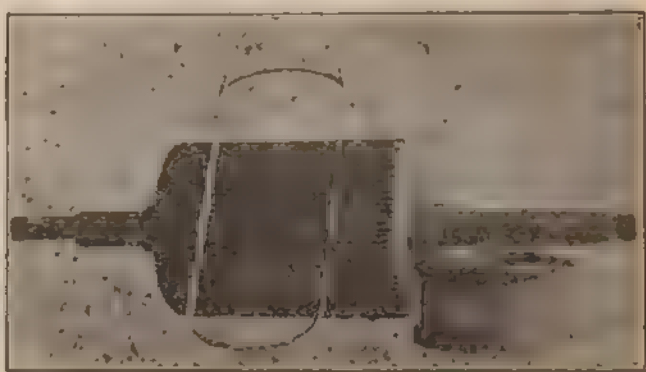
made entirely self-exciting, though the former plan is preferred for station work, or where great variation of load is expected. The exciting current from the dynamo is directly proportioned to the total armature current at all times, so that when it is fully loaded it will have maximum field. To maintain normal constant pressure in the mains, the external exciter current is fixed, and the internal exciter current varies the field to maintain constant potential under change of load.

The method of composite winding employed for this purpose is made simple by the use of a toothed armature. The armature is hollow, to allow of ventilation, and is built up of thin steel discs having T-shaped teeth on their peripheries. These discs are placed side by side, and clamped by rigid end plates. All the coils are lathe-wound, prepared previous to fitting, insulated with cotton

Toothed Armature and Coil.

and prepared tape. The coils are one by one slipped over the teeth, and pressed into place on the armature. It will be seen in the photograph that one of the coils has been slipped over one of the teeth, and a screw compressing arrangement is applied to the end of it. This squeezes the coil and forces it under the teeth, thus entirely surrounding the coils with iron. Wooden wedges are then driven in between adjacent coils, serving to keep the coils absolutely tight and to prevent noise through the armature teeth beating the air.

The armature thus constructed has no wire whatever on the outside of the toothed armature. It can be handled with ease, and even rolled along the floor without the

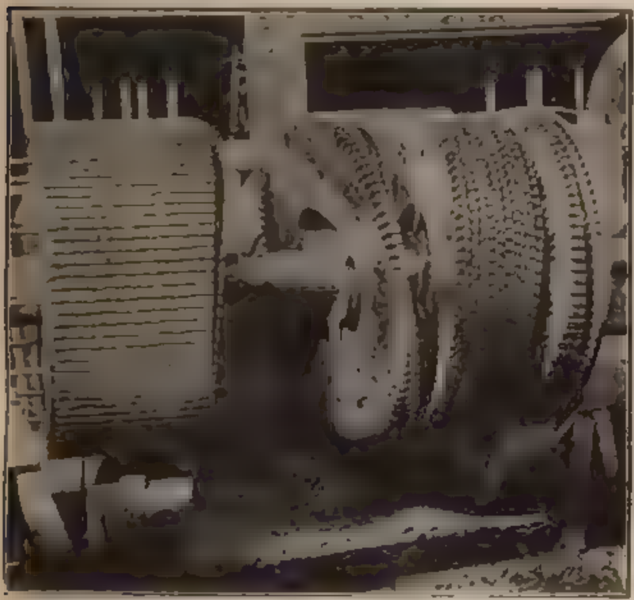


Street Car Armature and Coil.

least danger or injury. The enormous advantage of this can only be appreciated by the central-station engineer who has suffered delays and expense from the injury of surface-wound armatures. An increased clearance is also obtained, and will allow for greater wear of bearings, without appreciable extension of the distance between the iron of armature and the pole-pieces.

There is still another advantage claimed for these tooth-wound armatures. The chance of a burn-out cannot be entirely eliminated in station work. The burn-out is caused by the rush of current when the resistance at the

terminals is removed or suddenly lowered. Now, with the toothed armature an element is introduced which reduces this difficulty. By reason of the proportions of iron and copper used, and their arrangement with regard to each other, a transformer action is brought about for the creation of a high counter E.M.F. whenever excessive current tends to pass. Without defining the arrangement more exactly, the result may be mentioned: on short circuit, while the dynamo current increases in quantity to five times its normal amount, the E.M.F. simultaneously decreases to about one-fifth of its normal. The total dynamo output is approximately the same, and there is no burn-out or throwing off of belts. This method of winding is patented by the Westinghouse Company.



Direct Current Armature Discs.

We show two other methods of winding drum armatures: of the direct-current railway generator, and the corresponding motor armature.

RAILWAY MOTOR ARMATURE.

In the case of the motor armatures, as before, each coil is wound on a lathe, and is finished, insulated, and complete before being put on the armature. The simplicity of this method is apparent—the armature winder has simply to slip the completed coils into position. He does no handling of the individual wires, nor can he make any mistake as to the size of coil; and the judgment of the winder is not depended on for the efficiency of the insulation. The coils are bent to the special form shown, and simply placed in position, bound down, and their ends connected to the commutator.

Motor Armature and Coil.

Each coil is tested to stand 2,500 volts, and this is repeated when the winding is finished. This is five times the normal voltage of railway motors. Mechanically, the coils are held rigidly in the grooves punched in the discs, and no shifting of position is possible when starting under heavy load. To protect the armature outside, the insulation is bound over with band wires, not necessary to hold the coils, which are fixed in the grooves, but as added protection, and to render the surface smooth and ship-shape. The various stages of winding of motor armatures are shown in the illustrations.

TWO-CIRCUIT WINDING FOR MOTORS.

The method of connection is that known as the two-circuit winding. This winding, used in conjunction with a toothed armature, gives numerous advantages.

Direct-Current Generator Armature.

Though using a four-pole field, there are only two paths for the current, and two brushes only are preferred. One portion of the armature cannot carry more current than the rest, which, in ordinary armatures, sometimes happens from accidental change of position as regards the pole-pieces through wear of bearings. No high-tension wires cross each other, and there is no piling up of wires on the shaft. At the same time, the armature is small in size, accurately balanced, and solidly constructed. The drum armature, being directly keyed to the shaft, is truly centred, and no non-magnetic spider is required. The great difficulty with these spiders is the variation of coefficients of expansion of the bronze and the iron of the core, and the constant expansion and contraction tends to make the spider work loose. But it is essential that the armature core should be rigidly connected to the shaft, and should remain so under all changes of load; this renders a drum armature preferable, as rigid connection can only be secured by the use of the drum. There remains the question of circuit connection.

Motor Armature in Different Stages.

Engineers have been divided in opinion as to the advantages of four-pole and two-pole motors. The four-pole field is cheaper and has less magnetic resistance, and allows the use of a circular yoke, which is lightest and strongest for a given weight. But the two-circuit armature is preferable from the electrical point of view. The Westinghouse motor combines these two forms, obtaining the advantages of both types of machines.

DIRECT-CURRENT GENERATOR ARMATURE.

The railway generator armature, for continuous-current work, is built of large discs in the same manner as before

described, but in this case holes are punched in each disc, and the method of winding consists in simply threading thick wires, suitably insulated, one by one through these holes in the armature core and laid in the parallel slots, afterwards connecting them up to the commutator singly afterwards. In this case, of course, the coils are not "lathe-wound."

The armature is of the drum type, and is built up as shown. The method of winding and connecting to the commutator is similar to that used in the motor. The armature has only two circuits, and two or more brushes may be used. For the sake of proper collection of current four sets are used with the four-pole machine and six with the six-pole machine, since there is no inconvenience of having more brushes on a generator.

The two-circuit winding, as before, makes the armature circuits perfectly balanced. Eddy currents are obviated by preventing the wires from cutting the lines of force in the air-gap; this is managed by sinking the conductors below the surface. The lines of force then pass through the iron teeth, and the wires are shielded from eddy currents.

One great desideratum in railway generators is that there should be no change of lead from no load to full load, as change of lead means sparking. In order to prevent this the field must be at all times strong enough to overcome the reactive magnetism of the armature. In other words, the ampere-turns in the armature must be kept low. This is obtained by using a two-circuit winding in conjunction with a drum armature, with a minimum of conductors—one turn of wire per commutator segment. The wires are of large section, and carry the current efficiently and without undue heating.

This armature is not liable to mechanical damage from short circuit, as surface-wound armatures too often are, the sudden rush straining the connections to bursting point. Tests have been repeatedly made at the works by short-circuiting the generators without the slightest injury. This speaks exceedingly well for the Westinghouse armature.

The armature is evidently accurately balanced, and the insulation is of the highest kind. The insulation on each wire is tested to 10,000 volts alternating before passing the machine. Nor are there any high-tension wires crossing or touching each other, a great advantage, impossible to achieve with the ordinary drum. No two adjacent wires have a greater difference of potential than the two adjacent commutator bars. Finally, in this armature any wire can be replaced without disturbing the rest or removing the armature from the fields.

The great experience the Westinghouse Company have had in electric railway motor and generator work has enabled them, it will be seen, to produce electric machinery of the best type, thoroughly practical, and of sound mechanical design. The details we have given of their armature construction will, we think, be found of considerable interest to electrical designers and engineers.

GEOMETRICAL PROOF OF THE THREE-AMMETER METHOD OF MEASURING POWER.*

BY FREDERICK BEDELL AND ALBERT C. CREHORE.

The methods now well known for measuring power by three voltmeters or three ammeters, first shown by Prof. Ayrton and Dr. Sumpner,† are applicable to the measurement of power of any circuit irrespective of the nature of the impressed E.M.F., and the general proof of the methods is given in the paper referred to. In the case of an harmonic E.M.F. the methods are capable of simple geometrical proof. The writers have shown this‡ for the voltmeter method, and in this note will give the corresponding proof for the three-ammeter method.

Let R_2 L_2, Fig. 1, be an inductive circuit whose power is to be measured, and R_1 a non-inductive resistance in parallel with it. If the maximum values of the main and branch currents be denoted by I, I_1, and I_2 respectively, they may be represented as shown in Fig. 2. The current I_1 is in phase with the impressed E.M.F., E; the main current, I, lags behind it by an angle θ; and the current I_2 lags behind it by an angle θ_2. The tangent of θ_2 is $\frac{L_2\omega}{R_2}$; and the tangent of θ is $\frac{L'\omega}{R'}$, where R' and L' denote the equivalent resistance and self-induction of the parallel circuit*, and ω is 2π times the frequency.

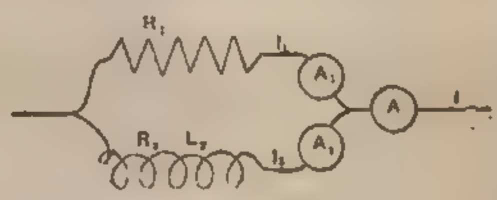


FIG. 1.

The power expended in the inductive circuit is $W_2 = \frac{1}{2} E I \cos \theta_2$. From the geometry of the figure,

$$\cos \theta_2 = \frac{I^2 - I_1^2 - I_2^2}{2 I_1 I_2};$$

whence

$$W_2 = \frac{E}{4 I_1} (I^2 - I_1^2 - I_2^2),$$

where E, I, I_1, and I_2 represent maximum values. Writing virtual or square root of mean square values as obtained from ordinary measuring instruments, the expression for the power becomes:

$$W_2 = \frac{\bar{E}}{2 \bar{I}_1} (\bar{I}^2 - \bar{I}_1^2 - \bar{I}_2^2).$$

The power in the non-inductive branch is

$$W_1 = \bar{E} \bar{I}_1;$$

and the total power in the two branches is

$$W = \frac{\bar{E}}{2 \bar{I}_1} (\bar{I}^2 + \bar{I}_1^2 - \bar{I}_2^2).$$

The method is thus geometrically established for harmonic currents, which may be represented by lines in a

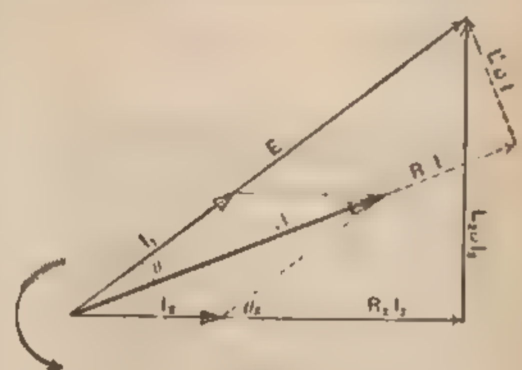

FIG. 2.

vector diagram. For an alternating current not harmonic the proof does not hold unless we assume the current to be equivalent to an harmonic current, and the question then arises as to what will be the equivalent harmonic current. The equivalent harmonic current must be such that its square root of the mean square value, and the expenditure of energy in the circuit, are the same as in the case of the given current which was not harmonic.

Fire Alarm.—An automatic fire alarm has been brought out by the Stettin Electricity Works for use in buildings. It is based upon the expansion by heat of air in a closed box, and which expansion completes the circuit and causes a bell to ring and a figure to indicate the number of the room in which the fire may have broken out.

THE NATURE OF DEPOLARISERS.*

BY HENRY E. ARMSTRONG.

I am induced to somewhat extend my recent note on depolarisers in order that the argument there made use of in considering the dissolution of metals such as magnesium in nitric acid may be clearly understood, and its consequences more fully realised.

It is one of the most noteworthy features of such interactions that when reduction is carried beyond the nitric oxide stage, it invariably proceeds to ammonia, and gives rise to a variety of products: so that whereas neither nitrous oxide nor nitrogen is evolved when metals such as silver and mercury are dissolved, these two gases are always obtained when more active metals are the agents From this it would appear that there is a limit of (?) E.M.F. which must be exceeded if it be desired to extend the reduction beyond the stage involving the formation merely of nitrogen dioxide and monoxide.

A somewhat similar case is presented by the behaviour of sulphuric acid solutions on electrolysis. Whereas, besides hydrogen, only oxygen is obtained under certain conditions, under others ozone, persulphuric acid, and hydrogen peroxide are also produced. This apparently is a phenomenon of the same order, but in a measure the converse of that presented by nitric acid, as oxygen—not hydrogen—is the active substance. Judging from McLeod's observations (C.S. *Transactions*, 1886, 591), it is clear that "current density" is an all-important factor in determining "peroxidation," but it remains to be determined whether it is the sole factor: the individual influence of E.M.F., of current strength and of current density, in fact, all require careful study in this as in many other cases of electrolysis; undoubtedly much depends on the concentration of the acid. The peroxidation may be regarded as the outcome of oxygen depolarisation, effected apparently in two ways: part of the oxygen becoming affixed to sulphuric acid, persulphuric acid is formed, which in part gradually undergoes hydrolysis, affording hydrogen peroxide—a non-electrolytic change; while another part serves as oxygen depolariser, affording ozone. On this assumption, ozone is not the product of the fortuitous concourse of three oxygen atoms, but of the interaction of oxygen atoms in circuit with persulphuric acid; and if this be the origin of electrolytic ozone, it appears not improbable that the oxidation of phosphorus, which is attended by the formation of ozone, will also be found to involve the formation of a peroxide hitherto undiscovered.

In the case of a metal such as magnesium dissolving in considerable excess of nitric acid, if a plate be imagined to be undergoing attack and conversion into nitrate at any one point, the displaced hydrogen may, it would seem, "travel along" a very large number of paths to other points on the plate capable of acting as negative pole and of there meeting with nitric acid in sufficient amount to oxidise it, and it is scarcely conceivable, therefore, that it should escape if the nitric acid act directly as depolariser. It is also difficult to understand why one substance—an electrolyte—should act in two ways in the same circuit, and the difficulty appears to be equally great, whether any form of Grothus's hypothesis, or a dissociation hypothesis, be adopted in explanation of electrolysis. But these difficulties seemingly disappear if—as previously suggested—the active depolariser be a nitrous compound or derivative; perhaps, at all events, at the initial stage, nitrogen dioxide. Moreover, it would appear to be possible in this manner to account also for the extension of the reduction to ammonia: in the case of a metal like silver the amount of depolariser must always tend to reach a maximum value depending on the extent to which the reversible interchange expressed by the equation $NO + 2HNO_3 = 3NO_2 + OH_2$ is limited by the concentration and temperature; but it is limited by these conditions alone. In the case of more active metals, it appears probable that the nitric oxide also functions as depolariser and is reduced to hydroxylamine and ultimately to ammonia. If such an action take place, it follows (from Ohm's law) that the more active the metal the more rapidly will hydrogen be displaced by it, giving greater opportunity, therefore, for nitric oxide to undergo reduction and leading to the production of an increased proportion of products of extended reduction. Any circumstance which would tend to diminish the proportion of nitrogen dioxide relatively to monoxide present in solution would therefore promote the formation of such products, and, in point of fact, Acworth and I have noticed, even in the case of copper, that when the metal is dissolved in diluted nitric acid, it appears to be more "active"—*i.e.*, to furnish a larger proportion of products of extended reduction—than when more concentrated acid is used; as the presence of water must obviously favour the reversal of the interchange expressed by the equation $NO + 2HNO_3 = 3NO_2 + H_2O$, so that weaker would potentially contain a larger proportion of monoxide than stronger solutions of nitric acid; these observations would appear to be in harmony with the hypothesis here advocated. There is no evidence, be it remarked, that hyponitrous acid can be formed in acid solution—*i.e.*, by direct reduction of nitric or even of nitrous acid; and the whole of the nitrous oxide which is evolved when metals are dissolved in nitric acid may result from the interaction of nitrous acid and hydroxylamine. That reduction invariably extends to ammonia whenever hydroxylamine is formed is probably a consequence of the extreme readiness with which hydroxylamine is itself reduced, so that, in fact, when reduction once proceeds beyond the nitric oxide stage, it is to be supposed that there are necessarily a number of competing depolarisers present in solution—nitrogen dioxide and monoxide and hydroxylamine and, perhaps, others—none of which, however, are electrolytes in the sense in which the term is ordinarily understood. And here it may pointed out that the fact that a nitrate may be reduced in alkaline solution by sodium amalgam, or aluminium, or zinc, is no argument against the conclusion above arrived at that probably nitric acid does not directly act as depolariser, as in these cases the alkaline solution appears to be the electrolyte, and the nitrate merely the depolariser, so that the nitrate does not act in two ways. As nitrates may be wholly converted into ammonia by reducing an alkaline solution, it would seem probable that in such cases hydroxylamine is not an intermediate product, as nitrogen is obtained on boiling an alkaline solution of this substance.

The argument here made use of would appear also to afford an explanation of the effect produced by varying the E.M.F.—*i.e.*, by metals of different degrees of "activity"—as increase of E.M.F., other conditions remaining unchanged, would increase the current strength, and consequently the rate of change; and, as indicated above, an increase in the rate of change would doubtless involve an increase in the amount of products of extended reduction.

It remains to be pointed out that the objection made to the assumption that nitric acid can act in two ways is equally applicable to the case of sulphuric acid; in other words, that it is not likely that sulphuric acid would act as electrolyte and as oxygen depolariser. It becomes necessary, therefore, to reconsider the manner in which solutions of this acid undergo electrolysis. On the one hand, it is conceivable that the water molecule alone suffers partition, not the sulphuric acid (H_2SO_4) molecule, as commonly supposed, and that under certain conditions the latter takes a direct part in the change, becoming oxidised; but this does not appear to be probable, especially as there is reason to believe that the acid in conjunction with water actually functions as electrolyte. An alternative assumption would be that the immediate product has been overlooked, and it can scarcely be gainsaid that there is much evidence in favour of this view. It is not improbable that the first products of electrolysis are hydrogen and persulphuric acid; it may be supposed that under "ordinary" circumstances this latter substance is resolved at the electrode surface into oxygen and sulphuric acid, but when the electrode surface is small much escapes unchanged, this being especially the case when the electrolyte is a somewhat concentrated acid—a condition which in itself favours the survival of persulphuric acid. Not only do recent observations on the electrolysis of various sulphates support this contention, but it would seemingly also explain the extraordinary character of the curve representing the change in conductivity of solutions of sulphuric acid on dilution.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence ; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices :

139-140, SALISBURY COURT, FLEET STREET,

LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139 140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations ; or it can, if preferred, be supplied direct from the Office, on the following terms :—*

	3 months		6 months		12 months
United Kingdom	3s. 3d.	...	6s. 6d.	...	13s. 0d
Other Places	4s. 11d	..	9s. 9d.	..	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank"*

BOUND VOLUMES.

Vol. XI. of new series of "The Electrical Engineer" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s*

ELECTRIC LIGHT IN LIGHTHOUSES.

We have received an interesting document which may be taken to embrace the evidence obtainable against the use of electricity for lighthouse purposes. It has often struck us that the future historian will have a hard task in deciding the truth of matters relating the end of the nineteenth century. If necessary, evidence can be produced for or against anything. There seems to remain not a single instance of desire to tell the truth, but on every hand the aim is to lie as bravely as possible in the interests of *our* side. With this object in view, it is easy to get testimonials in favour of electricity, or gas, or rushlights. You have only to ask a sufficient number to testify, and choose your sentences. Most people take sides nowadays, and if we want signatures in favour of felt hats we know where to go — as against straw hats, or in favour of whisky against Hollands. So this evidence respecting the electric light as a lighthouse illuminant—it is all very well till the other side interested produces its evidence. This is against the electric light, which is condemned because of "its intense and blinding effects," its not showing "so far in hazy weather," its easier obscuration by "fog," by "thick weather"; its brilliancy misleading mariners as to their "distance from it." The opinions, in fact, run in these two forms — "its misleading properties," "its obscurity in fog, hazy, and thick weather." Of course it is said to be worse, "far worse than oil or gas light." It is dazzling and unsteady. One captain says: "I am sure the new light will pierce fog far better than the electric light," which points to the view that this evidence has been collected by someone who has to push a "new light," be it gas or of oil. Another captain says: "I am of the same opinion as I have ever been—that the electric light for lighthouse purposes is a delusion and a fraud on the sailor. I nearly lost my life on Dungeness Point when the electric light was put there. The Trinity House yacht, Captain Wallace, got on shore there—so much for electricity." Prof. Tyndall is cited as against electricity and in favour of Wigham's light, as is Mr. Vernon Harcourt, who gives a reason for the obscuration of the electric light by fog, that "when a fog came on most of the violet rays were absorbed, leaving only the red. Therefore, the effect of the fog would be to cut off most of the violet rays, and leave a proportionately small number of red rays. In the case of oil and gas there was, of course, a similar diminution, but there was not the same loss, because the red rays were not nearly so much absorbed. It would be seen, therefore, that there was a great loss of intensity in piercing fogs with the electric light as compared with gas. It was a question whether in such a case it was worth while to use a light of such a high intensity, if a light with a lower intensity could be employed with equal advantage in fogs. The great point in lighthouse illumination was whether the light could pierce the atmosphere in foggy weather, there being quite light enough in ordinary weather. It appeared to him that it would be far better to use a gaslight of 5,000 candles, and to improve the appliances and,

if possible, the illuminating power of gas and oil lights, than to use the electric light for a purpose for which it was not suitable, so long as it was developed from carbon points." Now, Mr. Vernon Harcourt is a great authority, but we protest against a portion of this statement—that referring to the greater absorption of certain rays. Quotations are made from the paper of Cav. Dominico Lo. Gatto, read at the recent International Maritime Congress, but we are under the impression that Cav. Gatto stated at the congress that his views were considerably modified during the discussion at the congress. Hence, unless the quotations used have been since agreed to, they should possess no weight.

Let us admit that there is something in all this evidence; admit the whole as true if you like. What then? In the first place, it would mean certain alterations in the electrical apparatus to put it upon an equality with gas or oil. It is not impossible to so adulterate your carbons to give different coloured rays rays that are not liable to so great absorption; in the second place, you can easily make your light less brilliant, but so far as this part of the evidence is concerned, it is all moonshine. The only part worthy of discussion is the less effectiveness in fog, which arises, according to the critics, from the concentration of light too much at a point—a property which can be obviated—and the absorption of certain rays, which again can be obviated. We have never heard that electric light engineers possessed any influence to cause its adoption as against gas or oil. History seems to say that electricity was only adopted upon the advice of competent advisers. The conclusions of the advisers may have been wrong, but no one has yet attempted to get the evidence in favour of electricity, and till that is done no one is able to judge of the correctness of these conclusions.

"PRESSURE" OR "TENSION"?

Webster defines "tension" in seven different ways. When the word is used electrically, Webster says it means "The quality in consequence of which an electric charge tends to discharge itself, as into the air by a spark, or to pass from a body of greater to one of less electrical potential. It varies as the square of the quantity of electricity upon a given area." Various writers in the *Times* have been calling attention to the misuse of words, generally words which have been taken by us from the French. That shows how language is constantly being made. Thus, a writer wisely says "menu" is not a substantive—it is an adjective, and only in its Anglicised use is it made a substantive. Well, no doubt that is so, but the opinion may be ventured that a hundred years hence will see "menu" acclimatised in English dictionaries as a substantive with a pretty definite meaning. The ordinary run of men—foolishly, no doubt—seldom trouble about pure grammatical forms or dictionary meanings—it is sufficient for them if their hearers understand exactly what they mean. "Carte" may be good French, yet "menu" may be good English. We forget what writer it was who first said that English was such a wonderful language that it had no two words exactly synonymous; so that if a man really troubles about accuracy, he cannot well make a mistake. We are not much troubled about philologists or grammarians so far as the words in common use among electrical engineers are concerned. The redundant words will, in the nature of things, be gradually lost, and the words retained will be concreted in meaning. There seems at present to be a fight between the use of "pressure" and "tension." Which word is to be preferred in dynamic electricity? Originally the meaning of tension as given by Webster was undoubtedly obtained from the study of static electricity, and might now be approved in this use by engineers when considering what goes on, or is supposed by modern scientific men to go on, in the dielectric when a static charge is considered. The ordinary engineer approaches the use of electric apparatus from another standpoint. He is told that electrical science has many analogies in hydraulics, and at once an important factor is the action attributed to "difference of potential," which he proceeds to call "difference of pressure," and thus uses the word "pressure" to indicate, if we may so term it, the actuating force of an electric circuit. In ordinary correspondence one half the writers use "pressure," the other half "tension" to mean the same thing. What system do you use? The answer is just as likely to be "high or low pressure" as "high or low tension," and according to the doctrine of probabilities the betting is even upon either word. Perhaps the tendency is towards "pressure." It would be well to come to a decision upon the subject, as the philologists—if anyone cares about them—of 1993 may worry considerably over the difference in meaning between "tension" and "pressure," so indiscriminately used in the literature of the end of the nineteenth century. So far as we are concerned, a word may be coined by taking half-a-dozen letters from a hat so long as it is universally adopted, but we are confident that some objector would within a fortnight come along and propose something else, and reintroduce the confusion. It is the same all round. In the earliest days it was the "incandescent lamp," and "incandescent" it generally remains, though a few, to show their infinite superiority, use the term "glow lamp." It matters not—"a rose," etc.—but surely we might make an attempt at uniformity. Chicago will, perhaps, settle all.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ACCUMULATOR TRACTION.

SIR,—We never anticipated that a gentleman interested in overhead traction would advocate accumulators, and therefore Mr. Sellon may set his mind at rest and not trouble about any uneasiness which his remarks may cause us.

One of the possible reasons why the cost on the Bristol-road is higher than on any other line worked by the Birmingham Central Tramways Company is modestly hinted at by Mr. Sellon himself, and he will no doubt be pleased to learn that the management of the tramway company themselves are quite aware that a considerable reduction in the working expenses on the accumulator lir

can be effected, as will be seen on perusing Mr. Ebbsmith's remarks at the last meeting of the shareholders to the effect that "the Central Tramways was encouraged to proceed with the negotiations which had been held in suspense, and which the Board, after careful consideration by the engineers, were encouraged to believe would mean a profit to the company upon that line of not less than £2,000 per annum." For Mr. Sellon's edification we would like to add that we have pointed out to the tramway company several sources of undue expenditure which can easily be guarded against, and that we have offered them to work the line at a price considerably below the present one.

That the installation of any line on the accumulator system effects a saving of about 40 per cent. as compared with any other system in which the current is conveyed from a long distance, and that the working of such a line by means of accumulators can be effected at a lower rate per car mile than by any direct system, can in the face of such facts as exist only be ignored by those who are desirous not to be convinced.—Yours, etc., L. EPSTEIN.

REVIEWS.

Griffin's Electrical Engineer's Price-Book. Edited by H. J. DOWSING, M.I.E.E., etc. London: Charles Griffin and Co.

Builders and engineers have long had their price-books. An examination of these books will show that during the past few years as new editions were published a section has been devoted to electrical apparatus. The information given therein is necessarily meagre and incomplete, so that a price-book devoted solely to electric apparatus will be welcomed by all in the trade. For a first edition this book of Mr. Dowsing's seems exceptionally good. Great care has evidently been taken in the arrangement and selection of apparatus, and besides the price-list proper each section is prefaced by valuable information of a general character, relating, however, to the apparatus priced in that section. The great value of a price-book depends upon (1) correctness of prices; (2) ease of reference; and (3) selection of subject-matter. The correctness of prices means a laborious examination and analysis of manufacturers' latest price-lists, as does also the selection of subject-matter, though the latter also requires an extensive knowledge of the requirements of the case. All price-books tend to give too much. There are items priced which are not referred to once in the lifetime of the edition, and such items being generally of special apparatus seldom used, as a rule vary in price between the birth and death of an edition. In electrical matters it is as yet, however, doubtful what will be largely used and what will be seldom used, so that it is erring on the safe side to make the list as full as possible. For ease of reference in future editions, no doubt the index will be largely extended. Taking this book of Mr. Dowsing's as a whole, he has produced an exceptionally good work of reference, and so far as we can test by dipping into its pages at random, it is accurate. The type and figures of the book are excellent; but if a suggestion applicable to all such books might be made, it would be that every alternate line of figures should have a different face. The composition would be more costly, but it would be far easier for the reader to keep the lines distinct when making his reference. Printers are very averse to change, but they are studying more and more the wishes of readers. Altogether, this book approaches what may reasonably be expected as regards the specified requisites, accuracy, ease of reference, and well-selected matter, and we congratulate Mr. Dowsing upon his successful labours.

ELECTRICAL SYMBOLS AND NOMENCLATURE.*

The following communication has been addressed by Drs. Bedell and Crehore to Mr. A. E. Kennelly, member of the Committee on Provisional Programme, appointed by the American Institute of Electrical Engineers for the World's Congress of Electricians.

Sir,—In accordance with the suggestion made by you in a recent conversation on the subject of electric symbols and nomenclature, the system of notation given below has been tabulated by us and is offered as possibly including some material which might be incorporated into a uniform international system of terminology and abbreviation which will doubtless come up for discussion at the World's Congress of Electricians near at hand. The carefully-worked-out scheme of M. Hospitalier is a valuable foundation for a suitable system, and the following table has been made upon it as a basis, in conformity with it in the main, with such amendments and additions as seem advisable. In order that a comparison with the proposal of M. Hospitalier may be the more readily made, his system has been placed in a parallel column with the one now suggested.

Physical quantities.	Symbols.	Defining equations.	System of M. Hospitalier.
Fundamental.			
Length	L, l, r	......	L, l
Mass	M	......	M
Time	......	......	T, t
— definite period	T	......	—
— independent variable	t	......	—
Geometric.			
Surface area	A	$A = L^2$	$S = L.\,L$
Volume	V	$V = L^3$	$V = L.\,L.\,L$
Angle	a, θ, ϕ	$a = \frac{\text{arc}}{\text{radius}}$	$a = \frac{\text{arc}}{\text{radius}}$

* More strictly: $\mathbf{F} = \int \mathbf{H} \cdot dl$.

† More strictly: $N = \int \mathbf{B} \cdot dA$.

‡ More strictly: $dw = e\,i\,dt$.

§ More strictly: $P = \frac{dw}{dt}$.

Dashes indicate that symbols are lacking in one system or the other. An interrogation mark (?) has been used to indicate that a symbol is desired. The distinction between maximum values, instantaneous values, and square root of mean square values, thus, E, e, $\bar{E}$, etc., seems called for in alternating-current literature.

Suitable terms for the resistance, real and apparent, in an alternating-current circuit would be extremely desirable; thus:

$$\sqrt{R^2 + \left(\frac{1}{C\omega} - L\omega\right)^2} = \text{impediment};$$

$$\sqrt{R^2 + L^2\omega^2} = \text{impedance};$$

$$R = \text{resistance};$$

$$L\omega = \text{inductance};$$

$$\frac{1}{C\omega} = \text{condensance}.$$

All of these quantities have the dimensions of a resistance and may be expressed in ohms. For the last two quantities, $L\omega$ and $\frac{1}{C\omega}$, suggestive names, as "inductance" and "condensance" are particularly necessary, the terms "inductance speed" and "capacity-speed-reciprocal," already used, being quite cumbersome.

The use of n to denote frequency is already common, and may well be retained. For the quantity $\omega = 2\pi n$ one word, as "rotation" or "rotivity," is needed to take the place of the two "angular velocity."

In conclusion, we would suggest that the word "virtual" be always used to denote the square root of the mean square value of any varying quantity, and that the "effective E.M.F." be used to denote that component of the "impressed E.M.F." which is effective in overcoming ohmic resistance.

FREDERICK BEDELL.
ALBERT C. CREHORE.

Cornell University, July 21, 1893.

In the scheme given above we have used Gothic letters for vector or directed quantities. M. Hospitalier has since explained to us that he does not consider it advisable to introduce this distinction, taking the ground that, inasmuch as the exact nature of all physical quantities is not sufficiently understood to enable a proper distinction to be made in all cases, it would block further progress in this direction to try to introduce this distinction at present. It is, however, open to question whether it is not well to retain the start which has already been made in this direction. The word "reactance," which he has suggested for $\frac{1}{C\omega} - L\omega$, may well be adopted as indicating the presence of a reacting force which is not present in resistance.

ON THE TRANSMISSION OF ELECTRIC SIGNALS THROUGH SPACE.*

BY W. H. PREECE, F.R.S.

In the year 1842, Henry showed how the disruptive discharge of a Leyden jar in an upper chamber of his house magnetised needles in a cellar 30ft. below.

In 1884, telegrams sent to Bradford (England), in Morse characters, from the General Post Office, London, through a guttapercha-covered copper wire in an underground iron pipe, buried in the street, were read upon an open telephone circuit consisting of an iron wire carried on poles on the housetops 80ft. away.

In 1885, Mr. Edison showed how it was possible to communicate with a moving train by utilising the electrostatic influence between a circuit erected upon the poles on the side of a railway and a telephone circuit carried by the train.

In the same year, I made many experiments to determine whether the effects observed in England were due to electromagnetic induction, and were quite independent of the earth; and also to find out how far the distance between the wires could be extended before this influence ceased to be evident.

With our ordinary telegraph working currents the region of disturbance reached a distance of 3,000ft., while the effects were detected on parallel lines of telegraph, 10½ miles apart, between Durham and Darlington. Even between the East and the West Coasts at the Border, a distance of 40 miles, currents produced at Newcastle on the Jedburgh line were distinctly heard at Gretna on a parallel line. These latter results, in the North of England, were vitiated by the presence of a large network of railway and other telegraphs between the two places, and as they may not have been due solely to direct electromagnetic induction through space, but to electrostatic effects between neighbouring wires as well, I took a district in the West of England, between Gloucester and Bristol, along the banks of the River Severn, where for a length of 14 miles, and at an average distance apart of 4·5 miles, no intermediate disturbing conductors existed between the pole lines. The valley of the Mersey, and several other localities in England where no disturbing elements existed, were similarly investigated.

It is necessary at the outset to point out that if we have two parallel conductors separated from each other by a finite space, and each forming part of a separate and distinct circuit, either wholly metallic or partly completed by the earth, and called respectively the primary and the secondary circuit, we may obtain currents in the secondary circuit either by conduction or by induction, and we may classify them into those due to—(1) earth currents, (2) electrostatic induction, (3) electromagnetic induction.

It is very important to eliminate (1), which is a case of conduction, from (2) and (3), which are cases of induction.

1. EARTH CURRENTS.

When a linear conductor dips at each end into the earth, with which it makes a good connection, and voltage is impressed upon it by any means, the resulting return current would probably flow through the earth in a straight line between these two points if the conduction of the earth were perfect; but as the earth, *per se*, is a very

* Paper read at the Chicago Exhibition on Wednesday last.

poor conductor indeed (and probably is a conductor only because it is moist), lines of current-flow spread about symmetrically in a way that recalls the figure of a magnetic field. These diffused return earth-conduction currents are evident at great distances.

These lines of current-flow are very easily traceable by means of exploring earth-plates or rods. The primary current is best produced by alternating currents of such a frequency as to excite a distinct musical note on a telephone and if these currents rise and fall periodically and automatically, they produce an unmistakable wail. If they are made and broken by a Morse key, they can transmit readable signals. The secondary circuit, which contains the receiving telephone, is completed, in the case of the earth, by driving two rods into the ground, or, in the case of water, by plates dipping into the water at a distance of from five to 10 yards apart.

In this way the Town Moor, near Newcastle, the sands and the land about Lavernock and Penarth on the coast of South Wales, the water of the Bristol Channel, the towns of Liverpool and Leeds, and London itself, have been thoroughly explored, and it has been proved that the distance to which these lines of flow can be detected depends upon the intensity of the primary current flowing, on the area of the surfaces in contact with the earth, on the resistance of the portion of the earth utilised, and on the dryness of the season. In London the currents working the City and South London Electric Railway affect recording galvanometers at Greenwich, 4½ miles away, and a diagram of the train service on the railway can be recorded in any part of the metropolitan area.

The distance in sea water is not so extensive, for the latter is a better conductor than earth; still, with primary currents of 15 amperes, effects have been traced to one-third of a mile.

In all cases where disturbances have been created by electric tramways they have been shown to be greater in summer than in winter.

(To be continued.)

THE PRACTICAL MEASUREMENT OF ALTERNATING ELECTRIC CURRENTS.*

BY PROF. J. A. FLEMING, M.A., D.SC., F.R.S.

LECTURE I.

(Concluded from page 154.)

In accordance with what has been above said, it is necessary, when these balances are used for alternating currents, to avoid bringing any metal piece into contiguity with the coils. Accordingly the base of the balance is made of slate, and the coils wound on either slate or porcelain bobbins, or on some material which is a non-conductor. The balance is calibrated for use by means of a steady current, and it is then available for use with alternating currents. Lord Kelvin has devised a whole series of these instruments which are capable of measuring currents from one thousandth of an ampere up to 1,000 amperes, and each instrument has a range of about 1 to 100. The latest pattern of kilo ampere balance is shown in Fig. 6.

A reference has already been made to the electro-dynamometers of Siemens, and before you are a series of these instruments, lent to me by Messrs. Siemens Bros., and which are illustrated in Fig. 7. In all these dynamometers there is a fixed coil and a movable coil, both of which are traversed by the current to be measured. The current is got into and out of the movable coil by means of mercury cups, and the movable coil is brought back to its normal position when displaced by the current by means of the torsion of a spiral spring.

Another instrument of the electro-dynamometer class, but involving a slightly different principle, is one which I devised many years ago, and which depends on the principle of the repulsion of a copper disc by an alternating current. In this instrument there is a fixed coil of wire, which is traversed by the current to be measured. In the interior of this coil of wire there is a small copper disc, which is suspended by a fine wire. The disc is so placed that in its normal position its plane is inclined at an angle of 45deg. to the axis of the corner. When an alternating current is sent through the coil, the copper disc turns round so as to place its plane in the direction of the axis of the coil. The torsion of the wire resists this movement and the copper disc takes up some position of equilibrium. An instrument of this kind can be made to measure very small alternating currents, such as those of about one thousandth of an ampere. Quite recently I have determined the law of deflection of this instrument, and I find that the angular displacement of the disc from its position of equilibrium is

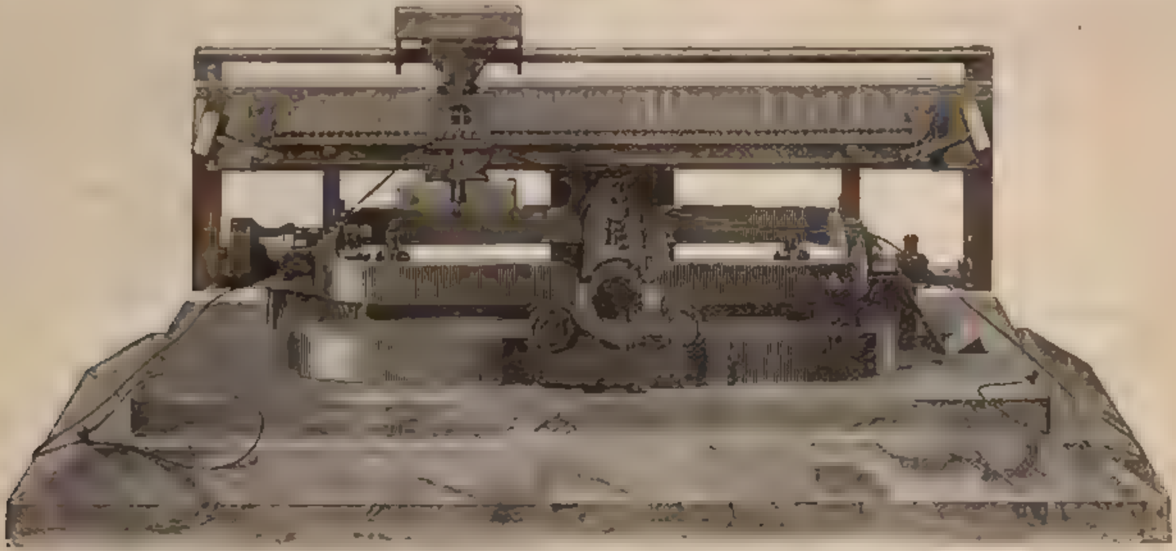

FIG. 6. Standard Kilo-Ampere Balance.

closely proportional to the square of the current strength passing through it. By attaching a mirror to the copper disc, the angular movements can be very much magnified, and the instrument then becomes available for detecting small alternating currents.

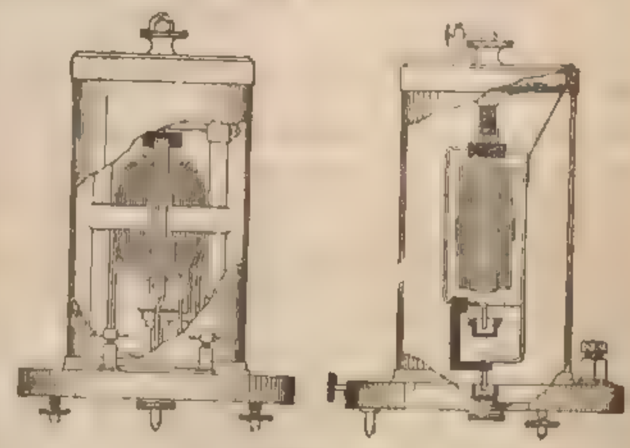

FIG. 7.

We must next pass on to consider instruments which depend on electromagnetic action, and in order to understand the principles on which such instruments act, we must investigate one or two elementary facts with regard to the behaviour of iron in a magnetic field. I have before me a small coil which I will place in a horizontal position in the field of the optical lantern, and in the centre of that coil I suspend a small fragment of iron. You

* Cantor lectures, delivered before the Society of Arts.

see on the screen the shadow both of the coil and the iron. On passing an alternating current through the coil, the piece of iron is drawn away from the centre of the bobbin, and moves up against the side. The explanation of this fact is that a piece of soft iron, when placed in a varying magnetic field, tends to move from places of weak to others of stronger magnetic force, and other things being equal, the force so displacing the iron at any point is proportional to the product of the strength of the field and the rate of change of the field at that point. We may show the experiment in another way. If we place a sheet of glass over the coil and sprinkle on it some iron filings, and then pass a current through the coil, the iron filings all move outwards from the centre of the bobbin to the edge, the reason for this being that the magnetic field of the bobbin is weaker at the centre than it is close up against the wire. This principle is employed in the construction of a large number of instruments. I have before me a selection of Prof. Elihu Thomson's instruments depending on this principle, and which have been lent to me by Messrs. Laing, Wharton, and Down, which are instruments employed for measuring alternating currents.

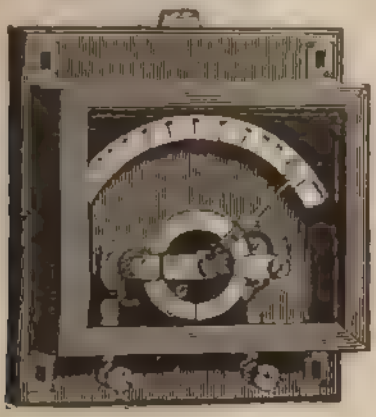

Fig. 8.

In these instruments, Fig. 8, a small plate of soft iron is attached to an axis which passes through the centre of a bobbin in such a manner that if the iron is displaced from the centre to the edge of the bobbin that movement is indicated by a needle. Hence, when an alternating current is passed through the coil, forces are brought to bear on the iron tending to displace it from the centre to the edge of the coil. A weight is so arranged as to resist this movement, and the instrument may be calibrated of different current strengths, and constitutes what is called the gravity instrument, because no springs are used in its construction.

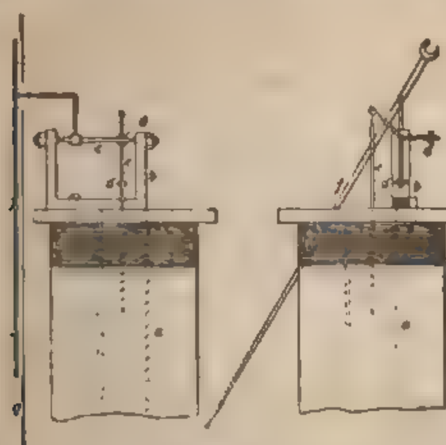

Fig. 9.

Another very similar instrument is that devised by Von Dobrowolsky. In this instrument, which is intended for the measurement of alternating currents, there is a coil of wire, Fig. 9, and in this coil of wire is suspended a very slender fragment of iron wire. When an alternating current is passed through the coil, the iron is drawn down into the coil owing to the tendency it has to move from weak to strong places in the field. This movement of the iron is resisted by the gravity of a small weight. A needle attached to the axis which carries the fragment of iron wire moves over a graduated scale, and the instrument can be calibrated as an alternating current ammeter.

Another instrument depending on the same principle is that of Nalder. In this instrument, which resembles in general construction the ammeter of Elihu Thomson, there is a fixed coil through which the current to be measured passes, and on an axis passing through this bobbin there is fixed a small plate of iron, the field of the binder is made stronger in one part than in others by placing a fixed plate of iron in the opening of the bobbin. When a current is passed through the coil the movable plate of iron is drawn towards the fixed plate, and in so doing turns round the axis to which it is attached. A needle fastened to the axis moves over a divided scale.

A fourth instrument depending on the electromagnetic principle is that of Mr. Evershed, of which I have examples lent me by Messrs. Goolden and Co. In Evershed's alternating current ammeter there is a fixed coil of wire through which an axis passes. This axis carries a small piece of soft iron like a hammer, which is fixed to the axis. Within the coil there are two soft iron cheeks, and between these is formed a strong magnetic field when a current passes through the coils. On passing the current, the movable piece of iron is drawn down between the two fixed cheeks, and this movement is resisted by a weight carried on the axis. The piece of soft iron therefore takes a definite position under any given current which depends on the relative forces acting upon the piece of soft iron. In these electromagnetic instruments it is important to know that in employing them for alternating currents the majority of them have to be calibrated for the particular frequency at which they are to be used. We must not take it for granted, in using an instrument of this class, that its readings will be identical for alternating currents of different frequencies. In the Evershed ammeter, however, a compensation is provided to meet this difficulty, and to make the instruments give identical indications, although the frequency of the alternating current may be varied. The working coil is shunted by an inductive shunt – this shunt takes about 6 per cent. of the total current as direct currents, but only about 2 per cent. as alternate currents. The result is that the working coil takes 2 or 3 per cent. more current with alternate currents, and eliminates any error due to eddy currents set up in the bobbin frame and case.

Before leaving the subject of electromagnetic instruments for the measurement of alternating currents, I may point out one instrument before me which can be employed for the measurement of such small currents as those produced by a telephone. In this instrument there is a fixed coil of wire, and in the centre of this coil is suspended a very small fragment of soft iron wire with its axis inclined at an angle of 45deg. to the plane of the coil. The wire is hung up by a cocoon fibre, and by means of a little fragment of mirror attached to the iron we can detect the smallest movement of the iron. On connecting a telephone to the coil and singing or speaking to it, you see that the iron needle is deflected. The alternating current produced by the telephone passing through the coils of the instrument creates a magnetic field in the interior, and the fragment of soft iron wire tends to turn round so as to place its greatest lengths in the direction of the field of the corner. Hence, the presence of a small alternating current can be detected. By making suitable arrangements and suspending the fragment of wire by a quartz fibre, it is possible to make an instrument sufficiently sensitive to measure the millionth part of an ampere.

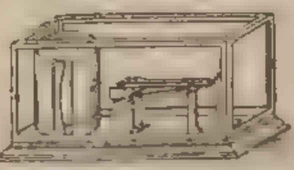

Fig. 10.

I now pass on to consider those instruments for the measurement of alternating currents of strength which depend upon the thermal principle, that is to say, depend for their action upon the heating of a conductor through which the current passes. The first of these which I will describe is the one which is called the twisted-strip ammeter of Profs. Ayrton and Perry. In this instrument a strip of platinoid is stretched between two supports and twisted round in the middle, so that the two halves of the strip form right and left handed spirals. When this is done, and the strip fixed at its two extremities, if an electric current is passed through it, and heats it, the strip tends to twist up more. If an index needle is attached to the centre of the strip, then the passage of a current through the strip may be made to cause this needle to move over a scale, and the position of the needle at any extent to indicate the current going through the strip. If the strip is enclosed in a tube made one third of iron and two thirds of brass, the ends of the strip being attached to the ends of the tube by an insulating support, then no raising or lowering of the temperature of the strip and tube, as a whole, will affect the length of the strip, and hence such an arrangement will constitute a compensation for external temperature. If, however, the strip be supposed to be cooled or heated apart from the tube, it will untwist or twist up more. In order to be able to observe the movements of the strip relatively to the tube, a slit is to be cut in the side of the tube through which the needle attached to the strip can project. In the real instrument the tube containing the strip is fixed on to a stout bracket which divides it into two parts, the compound tube having the same coefficient of expansion as platinoid. A needle attached to the centre of the strip projects through a cut in the tube, and moves over a divided scale. If a current is passed through the strip it heats it, and after a short time the strip assumes a certain definite temperature which is attained when there is a balance between the rate at which the heat is generated in the strip and the rate at which it is radiated to the walls of the enclosing tube. Accordingly there is a definite position of the needle corresponding to any particular mean square value of the strength of the current, and by passing steady currents through the instrument it can be calibrated for use with alternating currents. Such an ampere-meter can be made to read from about ·2 to 5 amperes, reading by hundredths

of an ampere. For the ready measurement of small currents the instrument is convenient, but there are certain difficulties connected with its use which are common to all such thermal instruments.

We may next take note of a very ingenious hot-strip ammeter, invented by Captain Holden, several examples of which, lent by Messrs. Pitkin and Co., are before me. In this instrument there are two metal strips, and (see Fig. 10) of the same length, section, and material. These strips are fastened together by rivets, or otherwise secured at the point E (see Fig.

Fig. 11.

11), and they are also fastened at the other ends to the framework of the instrument. These strips of metal are each of them of a horseshoe shape, and, from proper terminals, a current can be passed through one of these strips. If this is the case, the strip becomes heated, and, if one strip is heated, say the top one, whilst the other one remains practically of the same length, the compound strip will be obliged to assume a new position, as indicated by the dotted lines in Fig. 11. This distortion of the compound strip is made to affect a system of levers which multiplies the motion, and an index arm may thereby be caused to move over a scale, or to move a writing pen over a revolving cylinder. It will be seen that a general rise of temperature of both strips simultaneously, such as would be produced by taking the instrument into a warm place, will not affect the form of the compound strip, since each strip lengthens equally, and therefore there will be no turning movement.

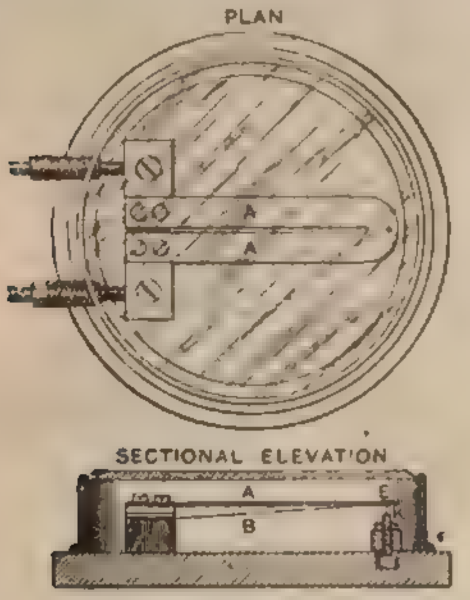

Fig. 12.

In Fig. 12 we have a plan showing the horseshoe shaped strip, the ends of which are attached to insulated blocks of metal, which form the terminals of the instrument. The controlling strip, which is fastened underneath, and is indicated by the letter B, is a plain strip, riveted at one end to A, and the other end to an insulated piece carried on the terminal blocks. Such an arrangement of compound strips may be employed, not only as an alternating current ammeter, but as a means for closing the circuit when a current is increased above a certain amount. A recording ammeter made on this principle, which is an exceedingly simple and effective instrument for recording the strength of large alternating currents, and the rigidity of the strip causes the ammeter to be remarkably dead beat. In the next lecture I shall proceed to describe how these principles are employed in the construction of instruments for the measurement of alternating-current pressure.

LECTURE II.

The Measurement of Alternating-Current Pressure.

Before proceeding to discuss the various types of practical instruments for measuring alternating current pressure, it is necessary to pay attention for one moment to a distinction between electric circuits. I shall have to employ frequently the phrases inductive and non-inductive circuits, and I wish you to be perfectly clear as to the exact meaning of these terms.

Every electric conductor has the property of producing a dissipation of energy when an electric current is passed through it, and it has also the property, as a natural consequence of the above fact, of producing a fall in pressure in the current falling through it. If we consider for one moment a continuous current flowing through a conductor, then if by suitable means we measure the potential at both ends of this conductor, we find there is a fall in potential, or, as it is called, a drop in pressure down the conductor. The number by which we must multiply the strength of the current in amperes to obtain the fall in pressure measured in volts is the numerical measure of the resistance of that conductor measured in ohms. The rate at which energy is being dissipated in that conductor is numerically measured in watts by the product of this resistance and the square of the strength of the current. So far, all is simple when we are dealing with unvarying currents. If, however, we are using alternating currents, then we should not find that the product of the resistance of the circuit and the $\sqrt{\text{mean square}}$ value of the current gave us always the $\sqrt{\text{mean square}}$ value of the drop in volts, neither would it be always true that the product of the resistance of the circuit and the mean square value of the current would give us the mean value of the power taken up in that circuit. In other words, the drop in volts which would actually be observed in the case of an alternating current circuit, especially if it is a circuit wrapped round iron, is more than can be accounted for by the simple resistance of the wire. We find we have in this case to take into account another quality of the circuit, which is called its self induction. In the case of such a circuit the number by which we have to multiply the $\sqrt{\text{mean square}}$ value of the current to obtain the $\sqrt{\text{mean square}}$ value of the E.M.F. is the measure of what is called the impedance of that circuit. We can always measure the resistance of a circuit by means of a Wheatstone's bridge, and if taking any circuit we find that when an alternating current is passed through it the ratio of the $\sqrt{\text{mean square}}$ value of the drop in volts down that circuit to the $\sqrt{\text{mean square}}$ value of the alternating current flowing in that circuit is greater than the true resistance of that circuit, such a circuit is called an inductive circuit, and the above ratio is a numerical measure of its impedance. I can best illustrate this by an example. Two wires, one of platinoid, and the other of manganese steel, were wound into spirals round a wooden frame. Each of these wires was about 25ft. long, and made 40 turns round the frame. In the first place, a continuous current was passed through each wire, and the fall in volts down each wire carefully measured, the magnitude of the current in both wires being ·802 of an ampere. The drop in volts down the platinoid coil was 67·9, and down the manganese coil 79·7 volts. Accordingly the ratio of volts to currents in the first place is 84·66, and in the second case 99·38. This being done, an alternating current of the same $\sqrt{\text{mean square}}$ value, as measured by a Kelvin balance, was passed through the two coils. The fall in volts down the platinoid coil was found to be 68·5, and down the manganese steel coil 80·7. These were the mean square values. The ratio of volts to current in the first case is therefore 85·41, and in the second case 100. These, therefore, are the impedances of these coils, and it is seen that in each case the impedance exceeds the resistance. The frequency of this alternating current was 108, and therefore these coils form slightly inductive circuits. I shall point out presently the manner in which practically non-inductive circuits may be obtained; but meanwhile it is sufficient to remark that if an iron core had been inserted in either of these coils, it would have greatly increased the impedance of that coil. It is always possible, however, to ascertain whether the impedance of a circuit differs from its resistance in numerical value. If it does not to any sensible extent, then the circuit is called a non-inductive circuit. If the impedance is greater than the resistance, then the circuit is called an inductive circuit. There are many cases in which inductive circuits cannot be employed, but in which we must secure, by some means or other, a practically non-inductive circuit. Such a non-inductive circuit can be formed of a series of incandescent lamps, and for larger currents it can most conveniently be obtained by using rods formed of a mixture of plumbago and fireclay, mixed in proper proportions to secure the necessary resistance, and then baked.

Turning now to the question of the measurement of alternating-current pressure, we will consider the various types of instruments which can be used for this purpose. In the first place, any one of the class of electro-dynamometer instruments or electromagnetic instruments described in my last lecture, which can be wound with very fine wire, so as to make a current-measuring instrument of high resistance, can thereby become an instrument for the comparison of alternating current pressure, providing that certain precautions are employed.

In the first place, we may make a high-resistance dynamometer by winding a dynamometer with a wire of high specific resistance and of necessary length. The impedance of this instrument is, therefore, a fixed quantity, provided that we are dealing always with alternate currents of the same frequency. The indications of the instrument are indicative of $\sqrt{\text{mean square}}$ value of the current flowing through it, and hence, by what has been above said as to the definition of impedance, it follows that the $\sqrt{\text{mean square}}$ value of the alternating current pressure at the terminals of the instrument will also be given by the instrumental reading.

In other words, we can take such a high resistance dynamometer and can graduate it for alternating pressure to any given frequency; but if the dynamometer has an impedance which differs sensibly from its true resistance, then, if calibrated for alternating currents of one frequency, it will not, in general, be identical in its indications for alternating currents of different frequency.

We can, however, nearly always secure the condition that the impedance of such an instrument shall differ by very little from its true resistance, and then, when once it has been calibrated, by

testing it with known unvarying pressures, it will enable us to measure alternating-current pressures giving us their $\sqrt{\text{mean square}}$ values.

In order to obtain the necessary non-inductive quality in such an instrument it is generally necessary to place the greater part of the resistance of the instrument in the form of a non-inductive coil of platinoid wire, which is placed outside the instrument, and then to a considerable extent we may be sacrificing sensibility. The same statements are true with regard to the employment of the electromagnetic principle in the construction of alternating current voltmeters. In all the instruments described in my former lecture Siemens's dynamometers, the alternating current ammeters made by Nalder, Evershed, Elihu Thomson, and Dobrowolsky, can be converted into alternating current voltmeters by winding them with very high resistance wires, putting that resistance in the form of a non-inductive resistance associated with the measuring part. In Evershed's current volt-ammeter there is a compensation for frequency which is worth noting. The voltmeter coil has placed in series with it a coil, the terminals of which are shunted by a condenser. This shunted condenser has the property of neutralising the self-induction of the voltmeter coil and if properly adjusted, the instrument may be made to give identical scale indications for alternating pressures of widely different frequencies, and be practically compensated for frequency.

Turning, then, to the instruments for the measurement of alternating E.M.F.'s in which the thermal principle is employed, we have, first, the well-known Cardew voltmeter as a typical instrument for the measurement of such alternating pressures. In this instrument a platinum-silver wire, of about 300 ohms resistance, is stretched in a tube, and, for the sake of compactness, the wire is folded backwards and forwards four times over small ivory pulleys. One end of this wire is fixed, and when a current is sent through the wire it becomes heated, and it attains a final temperature if the current passing through it is constant. The wire, therefore, elongates, and the expansion of the wire is measured and detected by a multiplying gear of the following kind. The elongation of the wire is made to cause a revolution of a mechanism consisting of an intergear of wheels and pinions, and to the last axis of the series an indicating needle is attached, moving over a divided dial. The wire has to be held in a tube or frame, and there are two types of this instrument, called respectively the rod and the tube type. In the rod

FIG. 1.—Holden Voltmeter.

type of instrument, which is the easiest to manufacture, the platinum-silver wire is kept extended by being fastened to two rods, formed one third of iron and two thirds of brass. The whole instrument is then enclosed in a brass case. When the current is passed through the wire it heats it, and the rods become heated also by radiation from the wire. It takes a certain time before the rods settle down into a final state of temperature, in which the heat received by them is equal to the heat radiated by them. Until this is the case, the instrument does not come to its final reading. In the other type of instrument, called the tube instrument, the wire is attached simply to the brass and iron tube, which forms the case of the instrument. In this latter type the outside tube arrives very much more quickly at its final state of temperature, and hence the instruments of the tube type are preferable for accurate work on account of the fact that they thus come much more quickly to their final readings when put upon the circuits. The Edison-Swan Company manufacture a type of Cardew voltmeter which is easier to string than the ordinary tube instrument, and yet has all the advantages of that instrument.

Another disadvantage which the rod instrument possesses is that there is generally a considerable negative variation of the needle, on taking off the current. The rods do not cool as quickly as the wire, and therefore when the current is taken off the needle goes back beyond the zero of the scale. The instruments are generally made for reading pressures from 40 to 150 volts. In the manufacture of the instruments the wire has first to be carefully aged by putting current on and off for some time at intervals of one minute, so as to heat and cool the wire. In this way a certain variation in expansion is got rid of, and the platinum-silver wire is brought into a condition in which it always is the same length and the same temperature. These Cardew voltmeters are really, of course, alternating-current ammeters which take a current of about one third of an ampere at 100 volts. The instrument of this range therefore dissipates a power of 30 watts, and, as I shall point out later on, has the disadvantage of wasting a considerable amount of energy if kept continuously upon the circuit, but when carefully made the Cardew voltmeter is an instrument of great value for measuring alternating current pressure. A special form of this Cardew voltmeter is also made by the Edison-Swan Company for engine room purposes, the dial of which is very large, and which is graduated say, from 80 to 110 volts. In this way such a graduation is given to the instrument that a variation of one volt can be easily seen at a considerable distance. There are some modifications of the Cardew voltmeter which are useful in measuring very small alternating E.M.F.'s, such as the voltmeter of Captain Holden, which you will see amongst the instruments lent by Mr. Pitkin. In this instrument a short and very fine platinum-silver wire is stretched between two supports, and it is kept sagged in the middle by means of a small spring (see Fig. 1). To the centre of the wire is attached a thread, also attached at the other end to the side of a small mirror. If the sag of the wire increases or diminishes, the mirror is more or less pulled round. When a current is passed through the wire it heats it. The sag increases and the mirror is moved. If I apply a very small current to the terminals of the instrument before me, given by a single cell of a battery, you see by the movement of the spot of light upon the screen that the instrument is capable of detecting a very small difference of pressure between its terminals, and, in fact, such an instrument is capable of measuring one hundredth of a volt alternating pressure. This instrument will measure without an external resistance from nothing up to two volts conveniently,

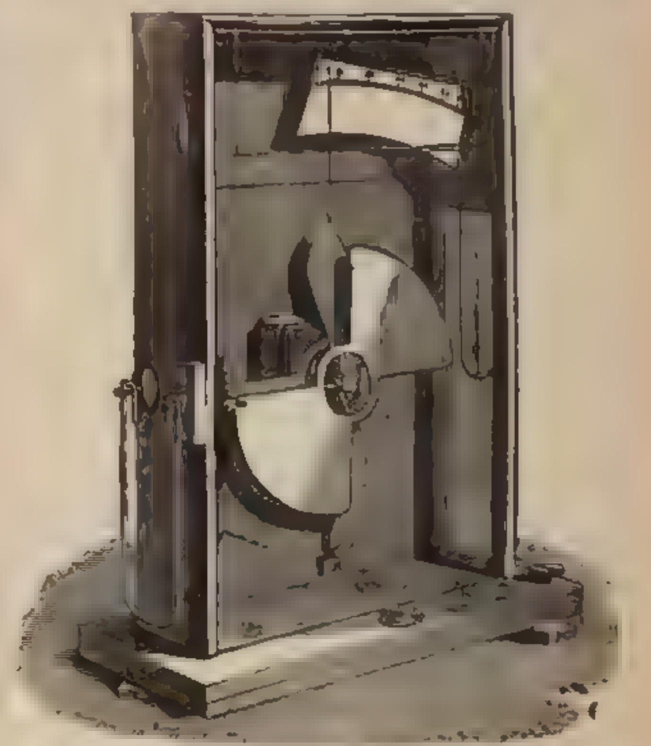

FIG. 2.—Lord Kelvin's Vertical Electrostatic Voltmeter.

and by putting the external resistance in series with it, and by employing a long ray of light, the instrument can be made to indicate pressures of any required voltage with great accuracy. Captain Holden has converted the above described instrument into a useful self-registering voltmeter making a photographic record of variation in pressure. This is achieved by letting the ray of light reflected from the mirror fall upon a revolving drum covered with photographic paper. The drum turns round by clockwork once in 24 hours, and the ray of light marks a photographic record of the revolving paper by which any variation in the pressure is detected and measured. A similar low voltage thermal voltmeter is constructed for use with secondary batteries for measuring the E.M.F. of each cell. In using such thermal voltmeters it is necessary to avoid convection currents of air in the enclosing tube or case. In using a Cardew voltmeter it is generally found best to place the instrument with the tube horizontal. In this way the variable cooling effects of the air currents in the tube are, to some extent, prevented. If a Cardew voltmeter is used with its tube vertical, the needle will be observed to make small movements to and fro, even if the current is perfectly steady. These movements of the needle may, if they occur, prevent the pressure from being accurately read within less than one volt.

We must now pass on to notice instruments for the measurement of alternating pressure which depend upon electrostatic attractions. These electrostatic instruments have for many purposes very great advantages, the most notable of which is that they do not consume power, and that therefore they may be left to the circuits indefinitely without cost. The first of these instruments which I will describe is Lord Kelvin's electrostatic voltmeter for high pressures. In Fig. 2 is shown a sketch of this instrument. You will notice that it consists of four quadrant-shaped plates which are connected to one terminal of the instrument. Suspended between these plates, but insulated from them, is a paddle-shaped

aluminium needle, which swings on very delicate pivots. The needle is connected to the other terminal of the instrument. The instrument in fact, forms a condenser, of which one plate is fixed and the other is movable. When a difference of potential, varying from 1,000 to 5,000 volts, is produced between the

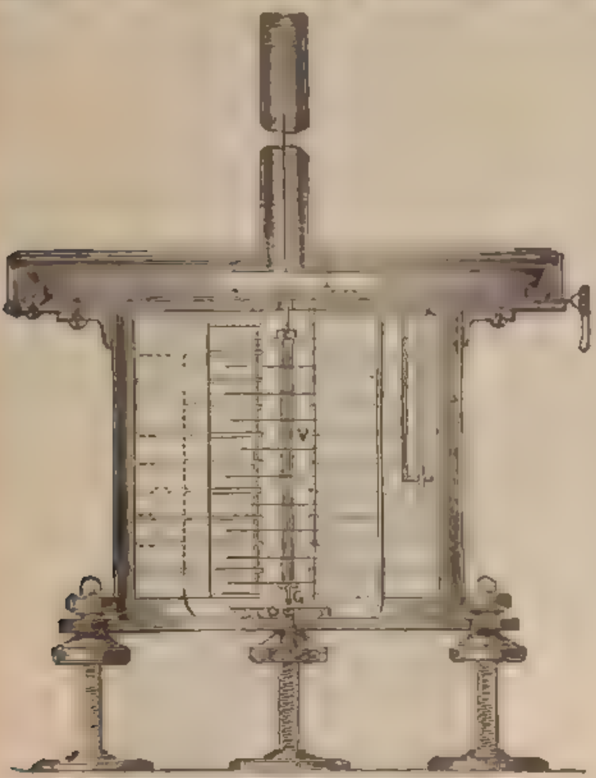

FIG. 3.- Multicellular Electrostatic Voltmeter.

terminals of the instrument, the movable plate is attracted in between the fixed plates. This movement is resisted by weights, which are hung on the bottom of the needle.

When two plates, in fixed positions, have produced between them a difference of potential, the force required to hold them in any given position is proportional to the square of the difference of potential between them. To the end of the aluminium needle is attached a long pointer, moving over a divided scale, and the instrument is graduated in such a manner as to read directly in volts. Since the attraction between the plates depends upon the square of the potential difference, it is independent of sign, and

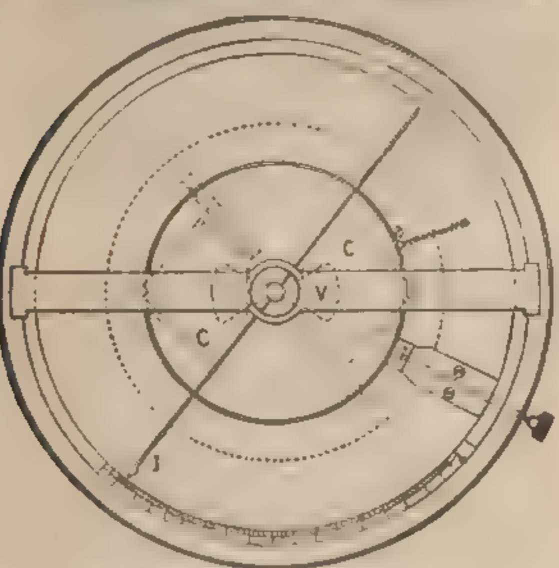

FIG. 4.-Multicellular Electrostatic Voltmeter

therefore the instrument works equally well with direct or alternating pressures; and, in this latter case, it gives us the $\sqrt{\text{mean square}}$ value of the potential difference between the terminals of the instrument.

Another instrument, also invented by Lord Kelvin, but adapted for measuring lower pressures, is the multicellular electrostatic voltmeter. In this instrument there are a series of quadrant shaped plates (see Figs. 3 and 4), placed one above the other, which are called cells. There are then a series of paddle shaped needles, all attached to a common axis, which is hung up by a platinum silver wire. The normal position of the needles is just outside the quadrants, but if a difference of potential is created between the needles and the cells, and the needle is drawn or attracted into the cells, this movement is resisted by the torsion of the suspending wire. An indicating needle, attached to the axis, moves over a divided scale; and the instrument, which can be arranged to measure from 40 volts upwards, gives us, therefore, the $\sqrt{\text{mean square}}$ value of the potential difference between the cells and the needle.

In these instruments there may be a very small error in reading, which is dependent upon the existence of a small E.M.F. of contact between different metals. If the cells are made of brass and the needle of aluminium there is a small contact difference of potential which is due to these different metals, and which may amount to something less than half a volt. Accordingly it will be found that in such an instrument reading, say, 100 volts, the reading given by

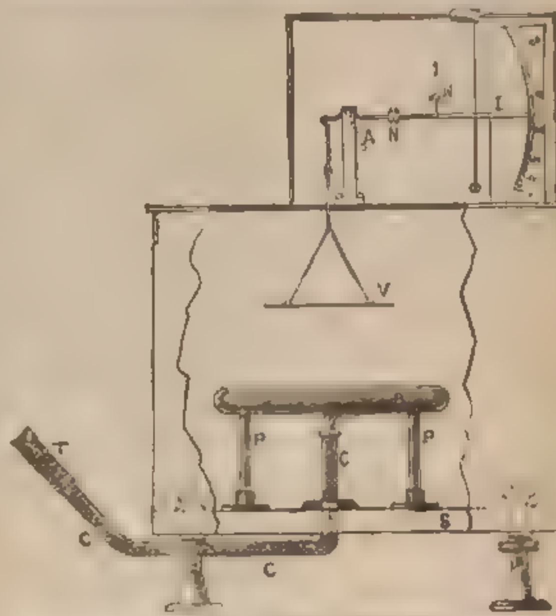

FIG. 5.-Electrostatic Balance.

the instrument will depend upon whether the cells are positive or negative, and a small correction has to be applied depending on the manner in which the instrument has been joined up in calibrating it. Similar instruments for measuring potential differences of much larger amount have been invented by Lord Kelvin. In Fig. 5 is shown the internal arrangements of an instrument intended for measuring from 5 to 40,000 volts. In this instrument the electrostatic attractions between two plates are balanced by the gravity of a weight. One of the plates is a fixed insulated plate, and the other a movable plate hung on a balance arm. The movement of a needle over a scale indicates the pressure in volts. Instruments similar in principle to the above have been devised both by Prof. Ayrton and Mr. Swinburne. In both these instruments the same principle is employed. There is a fixed insulated plate and a movable plate, to which is attached a needle. The electrostatic attractions between these plates are made to move the needle over a divided scale. Lord Kelvin has also devised a form of multi-

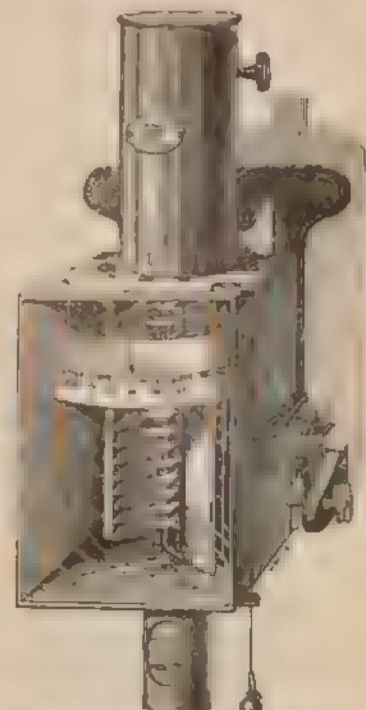

FIG. 6.-Electrostatic Voltmeter for Low-Tension Circuits.

cellular voltmeter, which is useful for central station purposes, as it has a vertical scale, and the instrument (see Fig. 6), is intended to be attached to a switchboard. I may now point out the advantage of these electrostatic instruments to which I referred a moment ago. Take, for instance, a thermal voltmeter absorbing 30 watts, and assume that this instrument is kept connected to the circuits in the dynamo room of a central station all the year round. Since there are, roughly, 8,000 hours in a year, this instrument, absorbing 30 watts, would in one year dissipate 240 Board of Trade units of electric energy. If we reckon this energy as costing 1d. per unit, it is evident that this instrument will cost 240d., or £1, per annum, to keep it going. In reading alternate current pressures higher than 100 volts, a transformer has to be interposed between the circuits and the voltmeter, to reduce the pressure. This transformer will also use up energy, and if it takes no more than the voltmeter it will also waste £1 worth of electric energy in the course of a year. We see, therefore, that an electrostatic instrument which wastes no energy at all is, in cost of upkeep, much superior to the electro-thermal or the electromagnetic type of instrument and, in fact, we can afford to spend a great deal more on an electrostatic instrument, and yet effect a total saving in the cost of the electric measurements in that station. For suppose we capitalise our £1 at 10 per cent., we can then afford to spend £10 more on an instrument of the electrostatic type than one of the electro-thermal or the electromagnetic type, which wastes no more than 30 watts if we keep them on the circuits always. There is, therefore, every reason to believe that in course of time electrostatic instruments for the measurement of pressure will entirely supersede instruments of the electro-thermal or electromagnetic type, in all those cases in which the instruments have to be kept upon the circuits constantly. We may employ these electrostatic voltmeters for the measurement of alternating currents, and convert them into alternating-current ammeters in the following way. Let a non-inductive resistance, say of platinoid wire, be constructed which is capable of passing without sensibly heating the current to be measured, and let the resistance of this wire be accurately known. Then to the ends of this circuit attach an electrostatic voltmeter. Knowing the difference of pressure between the ends of the resistance and its resistance, we know the current flowing through it. In many cases, as in measuring the primary currents of a transformer at no load, it is much more convenient to employ such an electrostatic voltmeter and non-inductive resistance than any other method. Suitable non-inductive resistance can always be made by coils of platinoid wire, joined in parallel; and these must be so adjusted that the final temperature they attain is not more than a few degrees above the normal temperature.

COMPANIES' MEETINGS.

BRUSH ELECTRICAL ENGINEERING COMPANY.

The fourth annual general meeting took place yesterday at the Cannon-street Hotel, E.C., under the presidency of Mr. J. B. Braithwaite, jun. (chairman).

The Secretary (Mr. B. Broadhurst) having read the notice convening the meeting,

The **Chairman**, before moving the adoption of the report and accounts which were published in our last issue, referred to the great loss that the Company had sustained by the death of the Duke of Marlborough, and to the resignation of Mr. E. Garcke (their former managing director), who had transferred his services to the Electric Construction Company, and whose position had been filled by Mr. A. Ayres. Turning to the balance-sheet, they would see that they had issued a certain amount of additional capital. The increase in the Company's business had been so persistent and so steady that they had found it necessary to enlarge the capacity of the Loughborough works, and more accommodation was now required. They had issued £15,000 in new preference shares, and £10,000 additional ordinary shares, for which they were fortunate in obtaining a premium, which, on the other side of the balance-sheet, amounted to £3,551. The debenture stock had been raised to £125,000, which was the total amount authorised. They now owed £37,000 less than last year, and which so far was a satisfactory position. There was an improvement on the balance of trade of £50,000 on the year. On the credit side there was an increase in the item of stock, but that increase represented additional work which they had in hand, and there was nothing in their works except for orders. That item now stood at £91,500, and there was an increase in the work in hand of about £12,000. Cash in hand showed an increase of £2,000, or £3,000 and debentures remained almost at the same figure. With regard to preliminary expenses, they proposed to write off the whole of them out of the year's profits. The liquidators' balance stood very much the same, and the balance of the foreign and colonial was £61,492 instead of £82,737, the greater portion of the difference being due to the sale of the Temesvar station. There had been a slight diminution in the standing charges, and the concentration of the works at Loughborough would lead to considerable economies. They were hardly yet settled down in their new quarters. During the current year they anticipated that the economies which they had effected by concentration at Loughborough would be very apparent, and they hoped to see that figure materially reduced this year. Passing on from other items, the Chairman said if the balance-sheet was sound last year it was very much sounder this year. It was very gratifying that, in spite of the paralysis of business in Australia, their English business alone had resulted in a profit of £50,000. Their shops were full of orders, and the only question was as to whether they could accept orders for delivery within a specified time. Their works in England and Austria were employing 1,300 men constantly, and their orders at home would practically keep them in full work until the shareholders assembled together again next year. It was however, necessary for them to keep their eyes open for new developments, and they had done so in three directions. The first was the completion of the large machines for the City of London Electric Lighting Company. They had undertaken to build for that company 400 kilowatt machines, which were four times larger than they had made. The 200 kilowatt machines last year had turned out well, and those of 400 kilowatts made this year had proved to be even more satisfactory—so satisfactory that the machine had been accepted as a 500 kilowatt machine, and had been paid for extra. Each of those machines could energise 15,000 8 c.p. lamps, and it was very necessary to be able to meet emergencies, because the demand sometimes increased five or six times in less than 20 minutes. The Mordey-Victoria machine was an alternator, and they could also supply continuous-current machines quite as good, if not better, than any other electrical firm in the market. They had, during the year, obtained the sole rights for England for the Desroziers dynamo, and they would shortly place the machines on the market, and he had no doubt that they would do a large business in the Brush-Desroziers dynamo. They had also taken up the manufacture of the Otis elevator, which worked in well with the car building works. He anticipated, in view of the large extension in electric lighting, to supply both motors and lifts. They had made that arrangement in order to have two strings to their bow in their car building shops as in their electrical department. The Company had not been a loser through the failure of the banks in Australia: things were now resuming their normal course, and they were beginning to receive remittances. In Austria their profits had suffered owing to the competition in the lamp trade, and they had now made that branch of a secondary nature, and had made arrangements to do installation work and to construct dynamos. After referring to the development of traction in the United States, the Chairman said that there now seemed to be some progress being made in this direction in this country. He said that electric traction would become an important part of their business at no distant date, and they had exceptional facilities for dealing with that kind of work, because they could not only build engines and motors, but they were also able to entirely complete orders themselves at their Falcon Car Works. When traction began to occupy a prominent place in this country, the Brush Company would be found to have a fair share of the work. Dealing with municipal electric lighting, he said that the Company had done well in the supply of plant. They had just started the Huddersfield station, and they had at present work in hand for Bolton, Leicester, Lancaster, Worcester, etc. They had an order for the supply of continuous-current machines, and they had done a considerable amount of work for private companies, as, for instance, at Coatbridge, Bournemouth, etc., and were doing other work for Canterbury and elsewhere. He referred to electric lighting in the metropolis in detail, and then spoke of the forthcoming expiration of the Edison master incandescent lamp patent. The Company looked forward to that because they believed it would assist materially in inducing people to adopt the electric light. They would soon resume the manufacture and sale of their incandescent lamps, and then they would be able to supply their customers with everything. He then moved the adoption of the report and accounts.

The motion was seconded by **Mr. B. H. Van Tromp**, and was adopted.

The **Chairman** then moved the payment of the dividends recommended. This was seconded by **Colonel F. G. Stouart**, and was carried.

The election of Mr. A. Ayres was confirmed. Messrs. Braithwaite and Van Tromp were re-elected directors, and the auditors, Messrs. Cooper Bros., were reappointed.

The proceedings terminated by votes of thanks to the Chairman and other Directors, and to the engineering staff.

ORIENTAL TELEPHONE AND ELECTRIC COMPANY.

The ordinary general meeting was held on Wednesday at the City Terminus Hotel. Mr. William Addison presided. In moving the adoption of the report, the **Chairman** congratulated them on the steady increase of their business, although the depreciation in the value of silver had prevented their showing any great improvement in the net results of the year's working as compared with the previous year. The appeal to the House of Lords had been allowed, and consequently there was a sum of about £13,000 owing by the holders of vendors' shares on account of interest payable to the holders of ordinary shares during the first five years of the Company's existence. He was glad to inform them that, after many representations to the Government of India in regard to the competition of the Indian Telegraph Department through that Department installing and undertaking to supply telephonic communication in districts for which they had granted licenses to the Company, the Government had seen fit to withdraw from the competition in these specially reserved districts. It certainly did seem unreasonable that the Telegraph Department should compete with this Company and its subsidiary companies, and at the same time extract royalties from the Company. Including the amount (£1,957) brought forward

there was a sum of £11,043 to be dealt with. The Directors proposed to add a further sum of £2,500 to the reserve fund, bringing it up to £12,500, all of which was invested in consols. The dividend now recommended was equal to £3 12s. per cent. on the ordinary shares. **Mr. Henry Grewing** seconded the motion, which was unanimously adopted.

BUSINESS NOTES.

St. Pancras. - We understand that Messrs. Johnson and Phillips have obtained a contract for these extensions.

Toxteth. —As will be seen by our advertisement columns, the Local Board require an inspector for electrical purposes.

Telegraph Insulators. —The strikers in South Wales, having nothing better to do, have been breaking telegraph insulators instead of coal.

Cleckheaton. —The Cleckheaton Local Board have decided to invite tenders for the fixing of electric alarm bells in the houses of all the members of the fire brigade.

Personal. —Mr. A. E. Pullen, of Bournemouth, has been appointed assistant electrical engineer to the Huddersfield Town Council at a salary of £130 per annum.

Watford. —Replying to Mr. Clifford at a meeting of the Town Council, the clerk stated that the matter of obtaining a provisional order for lighting the town by electricity was going forward.

Bury. -The Electric Lighting Committee of the county borough of Bury invite applications, as will be seen from our advertisement columns, for the appointment of a resident electrical engineer.

Barton. —The Workhouse Extension Committee have been instructed to enquire and report whether it would be more economical to light the new workhouse hospital at Patricroft with the electric light than with gas.

Babcock and Wilcox. —The directors of Babcock and Wilcox, Limited recommend dividends for the half year ended June 30 last at the rate of 6 per cent on the preference and of 10 per cent. per annum on the ordinary shares.

West African Telegraph Company. -The half-yearly interest, due on September 1 next, will be paid on and after that date by the National Bank of Scotland, 37, Nicholas lane, E.C. Coupons must be left three clear days for examination.

Telephony. —The National Telephone Company have arranged to keep their exchanges at Plymouth, Exeter, Torquay, and Paignton open day and night, including Sundays and holidays, and the trunk wires between those places will always be available.

City and South London Railway Company. —The receipts for the week ending August 20 were £860, against £724 for the same period last year, or an increase of £136. The total receipts for the second half year of 1893 show an increase of £526 over those for the corresponding period of 1892

Waterhouse Electrometric Syndicate, Limited. —This Company has been registered with a capital of £20,000 in £10 shares. The object is to adopt an agreement made between A. G. Waterhouse and A. T. Salisbury Jones of the one part and this Company of the other part, for the acquisition of certain patents, patent rights, etc.

Folkestone. —At a meeting of the General Purposes Committee of the Town Council on the 13th inst., Councillor Thompson asked the Mayor when he would be able to give them a day for the Electric Light Committee meeting. The Mayor said that he could not fix a day just that moment. He thought it would be within a week.

Bradford. —A tentative report has been presented to the Town Council by Mr. John Waugh, C.E., with respect to the type of engine to be used in the extensions of the central station. The Lighting Committee has resolved to extend the works and mains at a cost of rather more than £4,000, including the purchase of two engines and the switchboards.

Personal. -We are informed by Mr. W. H. Watkinson, of the Central Science School, Sheffield, that he has been appointed to a professorship at Glasgow. Mr R. Hammond informs us that he has decided in future to confine himself to consulting engineering, and that when the contracts to which he is at present committed are completed, he will only do consulting work.

Whitehaven. —The work of fitting the public lamps is progressing satisfactorily One or two local firms who are undertaking to fit up the electric light for private firms have received numerous orders, and have been kept busy for the past few weeks. It is expected that the public lamps will be lighted this week, and that the private supply will be available on September 1.

Blackpool. —The electric tramway on the promenade, and which was taken over by the Corporation on 9th September, 1892, cost the Town Council £28,964 Between that date and the 25th March this year, the expenses were £2,964 and the receipts £2,361, leaving a deficiency of £603. It is in the season, however, that the profit is made, and the accounts from March to September should present a much better appearance.

Telephony at Glasgow. —The Postmaster General, in acknowledging the receipt of the application by the Corporation of Glasgow for a telephone license, states that the matter is receiving his consideration. A communication on the same subject has been forwarded to the Postmaster General by the Association of Municipalities, who request to be heard before the postal authorities come to any agreement with the National Telephone Company.

Burton. —Through an oversight in our last issue it was stated that the Gas and Electric Light Committee of the Bolton Town Council had recommended the acceptance of the tender of Messrs. John Fowler and Co (Leeds), Limited, for providing an overhead crane, and that of Messrs. Bryan, Donkin, and Co. for fitting boilers and furnaces in connection with the electric light works. The name of the town should have been Burton, and not Bolton.

Micanite Insulation. -We are informed that Messrs. Bergtheil and Young, of 13, Walbrook, E.C., have been appointed sole European agents of the Mica Insulator Company, of New York, for the sale of micanite insulation. By its use it is claimed that the full benefit of the insulating properties of pure mica is obtained, together with the advantage that micanite is obtainable in large sheets up to 36in. by 36in., or even larger if required, and of almost any desired shape.

G. E. Belliss and Co., Limited. —This Company has been registered with a capital of £150,000 in 10,000 ordinary and 5,000 6 per cent. cumulative preference shares of £10 each. The object is to acquire the business of engineers and boilermakers now carried on by G. E. Bellias and A. Morcom, under the style of G. E. Bellias and Co., at Ledsam street Works, Birmingham, and to carry on the business of mechanical, electrical, and general engineers, boilermakers, etc.

Kelso. —The electric light installation at Newton Don, Kelso, for Mr. Charles B. Balfour, is now completed. Power is supplied by a turbine at the Lyna waterfall, which drives a dynamo from which the current is conveyed to the mansion by an underground cable some 500 yards in length. Altogether there are some 300 incandescent electric lamps. In addition to its use for lighting, electricity is also employed for boiling water, heating irons, and for other domestic purposes. The installation has been arranged and carried out by Messrs. A. A. C. Swinton and Co., of Westminster.

Direct Spanish Telegraph Company. —The report of the Direct Spanish Telegraph Company for the half-year ended June 30, states that, after providing for debenture interest, a balance remains of £4,646. After adding £2,500 to the reserve fund, the balance of profit and loss amounts to £2,146. To this the Directors propose to add £345 from the interest on investments, and recommend a dividend at the rate of 10 per cent. per annum on the preference, and at the rate of 4 per cent. per annum tax free on the ordinary shares. The reserve fund will then amount to £35,963.

Edmonton. -At a meeting of the Board of Guardians on the 16th inst., the Chairman suggested that while extensive alterations were now being carried out at the Edmonton Workhouse, it would be a suitable time for ascertaining what would be the cost of lighting the premises by electricity. It might be found that electric lighting would be more economical than gas lighting, and that there would be sufficient power for the purpose already in their engine room, or that it could be increased at very little cost now that other works were in progress. The matter was referred to the Works Committee.

Derry. —The municipal generating station is nearly completed by the contractor, Mr. Matthew M'Clelland, and Messrs. Alexander Brown and Sons are proceeding to place two boilers in position. A staff of men are engaged erecting the street lamp-pillars. The engines and machinery for which this firm have tendered are in a forward state, and will be erected as soon as the engine foundations are laid. Messrs. Siemens Bros. and Co., Limited, have two of the dynamos, and also the switchboard, ready for delivery, and the remaining dynamos are nearly completed. It is expected that this firm will proceed immediately to lay the street mains. The arc lamps will be fixed on the pillars as soon as these are placed in position. On the whole, the lighting scheme is in a fair way to be fully installed about the month of October, so that the city will be lighted during the coming winter. Various firms are prepared to light their works from the Corporation station.

Weybridge. —At a meeting last week of the Chertsey Union Rural Sanitary Authority, a letter was read from Mr. H. C. Buchanan, the secretary of the Weybridge Electric Supply Company. Mr. Buchanan wrote that Mr. Kite had forwarded him the Authority's letter drawing attention to Section 2 of the Weybridge Electric Supply Order, 1891, as confirmed by 54 and 55 Vic., cap. 105, limiting the time for removing the existing overhead wires. He had duly submitted the same to his directors, and, in reply, was directed to inform them that Prof. A B. W. Kennedy, F.R.S., had been retained on behalf of the company to advise as to the proper course to be pursued in reference to placing the electric lines underground. Unfortunately Prof Kennedy would be absent from London for some weeks, and therefore unable to give attention to this matter until his return. Mr. Buchanan, however, assured them that no time would be lost in removing the overhead wires complained of.

Scarborough. — The minutes of the Electric Lighting Sub-Committee adopted at a meeting of the Town Council last week were as follows: "The town clerk submitted draft deed of transfer from the Corporation to the Scarborough Electric Supply Company, Limited, as altered by the Board of Trade, together with their explanations how the alterations therein have been made. Resolved That the draft as altered be approved, except that portion of Clause 1 which provides that if any electric inspector be appointed his fees be paid by the local authority, and that the town clerk be instructed to inform the Board of Trade that the committee consider that if any electric inspector should be appointed, his fees should be borne by the company. Read: Letter from the resident engineer of the Scarborough Electric

Supply Company, Limited, enclosing tracing of proposed deviation from the original plan of mains in Filey-road. Resolved: That such proposed deviation be approved."

Bradford.—The chairman of the Gas and Electricity Committee of the Bradford Corporation (Alderman Frederick Priestman) has announced his intention of resigning that position in November next. He mentioned last week that they had had to refuse a large number of applications, and he believed that if they had double the quantity of electricity to sell customers would quickly be forthcoming for it. The committee had held back because they thought it desirable to ascertain whether they could improve their system, and they had consulted Lord Kelvin, who had recommended the three wire system. Lord Kelvin had also said that if the Corporation had to begin again to-day they could not adopt a better plan than they did five years ago. He hoped the committee would be able to get one of the engines which they proposed to order running before the winter set in, otherwise they must face the winter with some apprehension, because the work put on the engines and plant last year was more than it was safe for them to carry. They had not any spare power if one of their engines had broken down.

Bristol.—At a recent meeting of the Board of Guardians, the question of electric lighting at St. Peter's Hospital was referred to the Court of Assistants, who reported last week that they had considered the communication from the Electrical Committee of the Bristol Town Council, and that they found that the only expense the Guardians were asked to pay was in respect of about 80ft. of the "lead in" mains down the church path, costing about £9, the remainder of the expense of extending the mains to the front gate and 30ft. down the path being borne by the Council. The committee, therefore, unanimously recommended the Guardians to pay for the extra length of "lead in" mains at the estimated cost of £9, and to receive and pay, for a period of two years for electric light, not less than £4. 16s per annum. With regard to the supply and fixing of the necessary lamps, decided on by the Guardians on the recommendation of the committee on April 21, and then estimated to cost about £30, the committee thought it would be desirable that tenders should be now obtained, and asked for permission to take such action as they might think fit to obtain a specification and tender for the consideration of the Guardians. The report was adopted.

Harrogate.—In our last issue reference was made to the postponement of the decision of the Corporation in regard to the establishment of a municipal station. A decision has, however, now been arrived at. On Monday a meeting of the Corporation was held to consider the question. The question has been an open one for the past two years, the Council having taken up the Board of Trade powers to light the town with electricity. The time having expired, the General Purposes Committee decided to advertise for tenders from companies willing to supply electricity, and that, if so advised, the Board of Trade be communicated with with a view to the modification of the compulsory area of supply. At a further meeting of the General Purposes Committee, as mentioned last week, it was resolved to recommend that the Council should carry out the electric lighting order, and that Mr. Wilkinson, consulting engineer, should be instructed to work out the details of a scheme on the basis of the report presented to the committee, and that as soon as the scheme had been sanctioned by the Board of Trade, application be made for a loan for the establishment of the installation within the borough. The Mayor (Alderman Simpson) presided, and Mr. J. H. Wilson advocated the adoption of the electric lighting scheme by the Corporation. The resolution for the Corporation to undertake the lighting of the town was, after some discussion, carried by thirteen votes to seven.

Electric Lighting of Bolton.—Major General Crozier, one of the inspectors of the Local Government Board, conducted an enquiry on Tuesday at Bolton into the application of the Corporation to secure power to borrow £40,000 for electric lighting works, and £5,000 for works of sewerage. There was no opposition. The Town Clerk said the Corporation were empowered to supply electricity within the borough, the authorised area of supply being the whole of the municipal borough. A sub committee of the Corporation was appointed in 1891, which determined upon the alternating current high-tension system. The generating station would be placed at Spa Field. At present they did not contemplate street electric lighting. The necessary building and laying of plant were intended to be commenced forthwith, and tenders for almost the whole of the work had been obtained. The outlay at present involved would amount to about £21,000, but they had to consider and provide for the eventuality of being called upon to supply beyond the compulsory area. A point was suggested by the inspector as to the sum involved in the application over and above the amount actually to be expended at present. The Town Clerk stated, in reply, that they were liable at any time to be called upon to supply beyond the compulsory area. The Inspector suggested that £30,000 might be sufficient, and it was stated that this amount would permit of another engine and dynamos being laid down. This point was, however, left for the consideration of the Local Government Board.

Windsor and Eton.—The Windsor and Eton Electric Lighting Company stopped the supply last Saturday week, and has gone into liquidation. This company has had a somewhat chequered career, and can never have been in a strong position, or received general support in the district it was intended to serve. The *Windsor and Eton Gazette*, in a leader on the subject, says: "The stagnation—indeed, we may now say the stoppage—in the supply of electric light to the towns of Windsor and Eton is a scandal and disgrace to the community. The statement may be emphatic, but it is absolutely true—albeit, undirected against any individual or corporation. At a time when almost every town of importance has adopted the electric light, and when there are hundreds in Windsor wishing to avail themselves of the clean and wholesome illuminant, it is monstrous that either misfortune or mismanagement should debar all progress towards improved public and private lighting. The deadlock, which must be disastrous to those who have invested in the more or less moribund electric lighting company, cannot be ultimately beneficial to those who are interested in the supply of gas; and, so far as concerns the general interests of the two towns, it must, the longer it continues, prove increasingly disastrous. With the manner in which the existing conditions of things has been brought about we are not immediately concerned, nor, indeed, do we care too closely to enquire; but against the continuance of the present mockery to modern civilisation we do protest, and for the commencement of a brighter era of prosperity we enter our most earnest and solemn plea."

Lighting at Leicester.—On the 17th inst., Major General H. Crozier, R.E., Local Government Board inspector, held an enquiry at Leicester concerning the application of the Town Council to borrow £50,000 for the purpose of electric lighting. The town clerk appeared for the Corporation, and Mr. D. Wright said he opposed on behalf of the Ratepayers' Association. Mr. Storey said that the Corporation had determined to proceed themselves upon a provisional order, and this was granted in 1890. Since that time the Gas Committee had been pursuing enquiries in England and on the Continent, and the Council had accepted a scheme sent in by the Brush Company, whose tender amounted to £26,977, and whose plan had been recommended by Prof. Kennedy. The Board of Trade had also accepted it. The buildings would cost £4,000, and contingencies would raise the amount to £34,074, besides which the Council sought to take borrowing powers for £15,926 for future extension of mains, which was a moderate thing to do. The Corporation desired to have the electric light in their own hands, and not allow a private company to come in, who might have to be bought out in the course of a few years, especially as they already possessed the gasworks, in whose premises the electric lighting works could be built. Alderman Lennard said the Corporation already had applications for 4,000 lights, and the plant would supply 7,200 lights of 16 c.p. The price to be charged would depend upon the demand. The Corporation were going to work the scheme as a commercial undertaking. Mr. Wright opposed the application, urging that the matter should be delayed for five years in view of the heavy rates with which the town was burdened. The Inspector pointed out that unless the Corporation acted at once the Board of Trade might allow a private company to step in, which would then obtain a monopoly, and if the Council desired to obtain possession of the work they would have to buy them out as in the case of the gas and water works. The Ratepayers' Association could not expect to have the same weight as a Corporation representing the town.

Aberdeen.—The subject of the powers of the National Telephone Company was discussed at a meeting of the Town Council on the 21st inst. Mr. Bisset moved "That the Town Council petition the Postmaster General to lay on the table of the House of Commons, unsigned, the terms of agreement at present being negotiated by him with the National Telephone Company." He said this matter had now got into a very critical position so far as municipalities were concerned, and the Association of English Municipalities and several of the larger towns, both in England and Scotland, had already entered into communication with the Postmaster General on the subject. An understanding had got abroad—whether it was well founded, of course, they were unable to say—that the Postmaster General had entered into an agreement with the Telephone Company conveying to them all the powers which he possessed under the Telegraph Act and subsequent Treasury minute, and if that understanding was correct, the National Telephone Company would have got what would practically mean statutory powers to enter upon property and take lands for the purposes of their undertaking. He thought that every town council would at once admit that it would be a very serious thing if any company were to be allowed to enter upon the streets of a city for the purpose of putting down underground cables for telephonic communication; and that was what was contemplated, because a committee of the House of Lords and the House of Commons which had had the question under consideration, had condemned the system of overhead wires, and had recommended that the undertakers of telephonic communication should get powers to put the cables underground. If that were to be done they must very carefully watch the nature of the powers to be granted, and he thought it would be well for the Town Council to protect themselves by insisting that the terms of the agreement should be made public, so that everybody might know what they really were. He would also suggest that the town clerk be asked to write the local members of Parliament to use their influence in getting the agreement made public before the Post Office Department agreed to it. If that did no good, it could certainly do no harm. The fact that other bodies were taking up the matter was *primâ facie* evidence that there was some reason for Aberdeen moving in it. The matter was referred to the Finance Committee.

Worcester.—At the quarterly meeting of the Town Council on the 15th inst., the Mayor moved a resolution, "That the Council adhere to the proposal that the generating station shall be constructed at Powick Mills; that the Council accept the tender of Mr. Thomas Rowbotham, of Coventry road, Birmingham, for the erection of the electric lighting generating station at Powick Mills, in accordance with the plans and specifications prepared by

the surveyor, and with brick structure, for £14,797, subject to Mr T. Rowbotham entering into a contract for the work containing such provisions as the town clerk may think necessary, and also to order that the common seal be affixed to the contract." The Mayor said it would be recollected that at the last meeting a motion was brought forward to ask Mr E. D. Marten to report on the cost of making the Teme navigable up to Powick. The resolution was withdrawn on the understanding that the matter would be reintroduced at that meeting, when there would also be a report on the comparative cost of erecting a generating station at Powick, and erecting a station in the city. The committee had had reports from the city surveyor and from Mr W. H. Preece, upon whom they had looked, and hoped to look as their consulting engineer. The reports set out in a simple and complete manner the advantages of a station at Powick Mills over a smaller station erected in the city. Whatever doubts they might have had as to the wisdom of obtaining electric energy from water power had altogether been cast aside by the fact that in spite of the long and protracted drought there had been no day when less than 300 h.p. would have been available at Powick. Such a large horse-power would enable them to produce electrical energy at one-fifth of a penny per unit. Knowing the liability of estimates to be under the mark, he would take it at ½d., even ¾d. per unit. It might seem a large sum to put up a small station; but when they had such power running to waste which could be usefully employed in various developments likely to take place, it would occur to them to look 5, 10, or 15 years ahead, and forestall the future. The difference between £26,000 and £40,000 was not to be lightly despised, and it was quite possible that the £40,000 would amount to nearer £50,000. When he told them that by going to Powick they would produce their energy at one-sixth of the cost at a steam station, that was a sufficient reason to go outside. It might be asked, why go to such expense when the lights to be taken were so problematical? He admitted that unless the Corporation and the citizens were going to do the best they could for the city, then, by all means, let them not go to Powick. But the Corporation ought to support what the majority considered for the welfare of the citizens and the city. If they were to be met by what ought to be city interests going in an opposite direction to that the Council wished—he need not mention the particular case he had in mind—and if the Council were not going to use the electrical energy at so small a cost for motive power with regard to pumping machinery for water and sewage works he was afraid that any scheme of that magnitude—even though they could produce at so small a figure as ¾d. per unit—would be no use whatever. They would have to pay for the land in any case. They had committed themselves to an expenditure of £5,000, so that the approximate cost of the lesser scheme would be £31,000, because of the unproductive initial expenditure of £5,000. Unless the opinions of the experts consulted were altogether wrong, they should abide by their original determination, supported as it was unanimously by the Watch Committee. If they went to Powick, before very long they would have to light their streets by electricity. Their gas bill now amounted to £3,200 per annum, and that money would more than repay annually the amount they would have to disburse in the repayment of the principal and interest on the £50,000. There would be certain necessary expense in first substituting electric light for gas, but the benefits likely to accrue and the certain economy were sufficient argument for electricity. If they did not light the city by electricity, they would deprive them at once of an enormous revenue. In passing, he remarked that after a 12 months' trial the city of London were perfectly satisfied with the electric light, which was being worked by the same company as would do the work in Worcester. He thought members ought to have no fears as to the success of the enterprise, which, he ventured to hope the Council would see their way to sanction. Alderman Hill seconded, thinking the Council by that time thoroughly understood the subject. Mr Millington said he was not opposed to electric lighting. He was strongly in favour of it, and would support having it at almost any cost. He moved the amendment simply because he thought that the end might be attained by cheaper means. To adopt the Powick scheme would be to tax the ratepayers heavily; and by beginning in a small way they could take advantage of future improvements. He moved as an amendment that the Powick site be abandoned, and that the committee be instructed to put down plant with a steam generating station in the city of Worcester, at a total cost not exceeding £20,000. Further discussion then took place, and on the amendment being put, it was lost by 22 votes to 10, and the original motion was carried with five dissentients. The Mayor moved that Mr W. H. Preece be retained as engineer at a commission of 2½ per cent. Alderman Ernest Day seconded, considering that by appointing Mr Preece they would be certain the work would be carried out efficiently and well. The motion was adopted.

PROVISIONAL PATENTS, 1893.

AUGUST 14.

15409. **Improvements in electric switches.** Benjamin Greenwood Smith, Penny Bank chambers, Halifax.

AUGUST 15.

15476. **Improvements in primary voltaic batteries.** Luis Falero, 100, Fellows road, London.

15485. **Improvements in glow lamps and holders.** Edward Mann and James Hopwood, 77, Chancery-lane, London.

15479. **Improvements in electric arc lamps.** Louis Emerson Howard, 115, Cannon street, London. (Complete specification.)

15486. **An automatic switch for electric and other light, applicable to a door.** Edward Mann and James Hopwood, 77, Chancery lane, London.

15510. **Improvements in electric arc lamps.** James Brockie, 28, Southampton buildings, Chancery lane, London.

15519. **Improvements in electric engines.** Reginald Walter Barker, Monument chambers, King William street, London. (The Lawrence Electric Company, United States.) (Complete specification.)

15523. **Improvements in recording meters for electric light and power circuits.** William McNeill, James Henry Tinder, and Smith Peter Kerr, 53, Chancery lane, London.

AUGUST 16.

15577. **Improvements in electric furnaces.** Frédéric Chaplet, 46, Lincoln's inn fields, London.

AUGUST 17.

15610. **Improvements in apparatus for the electrolytical decomposition of brine and other liquids.** Francis Gibson Baily and Malcolm Guthrie, 46, Lincoln's inn-fields, London.

15617. **Improvements in apparatus for the electrolytical decomposition of brine and other liquids.** Francis Gibson Baily and Malcolm Guthrie, 46, Lincoln's inn fields, London.

AUGUST 18.

15663. **Improvements in the covers and frames of manholes, used for drainage work, electric light, and other purposes.** Frederick Charles Lynde, 25, Cross street, Manchester.

15669. **Apparatus for the electrolytic treatment of liquids.** Newnham Browne, 73, Cheapside, London. (Alfred Vogelsang, Germany.) (Complete specification.)

15681. **Improvements in electric accumulators or storage batteries.** George Henry Roe and Gustav Sutro, 52, Chancery lane, London. (Complete specification.)

15690. **Improvements in electric marine governors.** David Tweddle, 46, Lincoln's inn-fields, London.

15715. **Improvements in or connected with means for the supply or distribution of electricity.** William Godson Little and Charles William Godson Little, 47, Lincoln's inn-fields, London.

AUGUST 19.

15736. **Improvements in and relating to machinery for covering telegraph, telephone, and electric cables, and wires with lead or metallic compounds, also applicable for the manufacture of metallic pipes and the like.** George Edward and Thomas Edward, 70, Wellington street, Glasgow.

15776. **An improved electric apparatus termed "guberno graph" for use on ships to indicate and register the position of the rudder and the reversing gear of the engine.** Joseph Leopold Huber, 45, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED

1892.

17160. **Telephone switchboard apparatus.** Kingsbury. (Western Electric Company.)

17246. **Electric batteries.** Rawlins.

1893.

519. **Electric resistance boxes.** Lake. (Weston.)

9358. **Electric lighting, etc.** Binswanger.

11099. **Electric glow lamps.** Lake. (Colby.)

11680. **Electric alarm apparatus.** Sauer and Hentzschel.

12457. **Electric conductors.** Urquhart and Small.

NOTES.

Quintin.—Extensions are to be made in the electric lighting plant.

South Africa.—A telegraph line is being erected between Campbell and Griquatown.

Gibraltar.—The colonial report for Gibraltar states that the Electric Light Loans Ordinance was passed last year.

Dortmund.—The electric tramway now being constructed is expected to be set in operation by the end of the year.

Manchester.—Questions are being asked as to when the supply of light to the public will be available from the municipal station.

Kingston-on-Thames.—The Town Council expect to be in a position to supply current in October, the charge being 6d. per unit.

Mining Engineers.—The annual meeting of the Federated Institution of Mining Engineers will be held in Glasgow next week.

Mans.—The Mans Chamber of Commerce has decided to establish an urban telephone system and a circuit between Paris and Mans.

A Large Corona.—The main building of the Imperial Diet has been equipped with a large corona containing 12 arc lamps and 250 incandescent lamps.

Finland.—It is proposed to establish a State telephone system, and as a commencement the work of connecting the towns of Abo and Viborg has already been begun.

Telegraphy.—An enterprising individual a few days ago, at a Liverpool telegraph office, used no less than 146 forms in trying to word a message within the prescribed value of 6d.

Exhibition at Madrid.—A Universal Exhibition is to be held at Madrid from April 1 to October 31, 1894. The prospectus may be obtained at the Spanish Consulate, 23, Billiter-street, E.C.

Lighthouse Illumination.—The Commissioners of Irish Lights are seeking statutory sanction of the Board of Trade for the installation of the electric light as a fixed light at the Old Head of Kinsale.

Museum-Lighting.—The working expenses, including repairs, of the electric light plant at the South Kensington Museum reached £1,267 last year, and at the Bethnal Green Museum they amounted to £528.

Traction.—Electric traction people should look after the Dudley and Wolverhampton Tramways, Limited, which has been formed to acquire the undertaking of the Midland Tramways Company, and construct tramways in the county of Warwick.

Lighting of Spinning Mills.—The various buildings belonging to the firm of Petrikowsky and Co., at Schwedewitz, near Zwickau, are lighted electrically, and the spinning machinery is operated by electric motors. The power is supplied partly by steam-engines and partly by turbines.

Overhead Circuits.—The work of abolishing overhead poles and wires in New York City is still going on. It is stated that during the month of July the electric light companies removed a large number that had been condemned, to the extent of 24 poles and no less than 233 miles of wire, without expense to the city.

Live and Learn.—Mr. Edison has been engaged in seeing the wonders of the World's Fair. He has, of course, been asked his opinion of the exposition, and has said: "No man who has to make a living by his intellect can afford to stay away from it. I put it on a business basis. I find new ideas of motion and many other things in everything I see. It is all a study for me."

Llandudno.—A scheme is proposed for establishing a *funiculaire*, or cable tramway, to one of the highest points on the Great Orme's Head. Dr. Nicol, chairman of the Pier Company and the Marine-drive enterprise, is taking a warm interest in the matter, and it is said that the whole of the money is ready for undertaking the work. Here is probably an opportunity for the line to be operated electrically.

Low Water.—The Neversink Mountain railroad and one other electric car line at Reading, Pennsylvania, have been obliged to stop running for a time on account of the drought, their power being derived from a waterwheel in a river which is also used to feed a canal. One would think it a pity that, in view of some such possible occurrence, a small steam plant was not erected as a stand-by in case of emergency.

Military Telegraphy.—The cables which in military ports form connections between the works of defence and the network of submarine conductors terminating at torpedoes and at alarms are frequently within the reach of passers by in France. The importance of maintaining regular working in time of war has induced the French Minister of Marine to take steps to ensure proper supervision of these lines.

Bristol Industrial Exhibition.—The main building in which the Industrial and Fine Arts Exhibition is being held this week is lighted by 20 arc lamps of 1,000 c.p. and about 400 incandescent lamps of 16 c.p. Eighteen arc lights illuminate the industrial section. The arts section is lighted entirely with incandescent lamps, electroliers of numerous designs being brought into requisition. The current is obtained from the Corporation works. A searchlight has been placed on one of the towers.

The Junior Engineering Society.—The annual summer excursion of this society, which has just taken place, passed off in a very successful manner, the whole programme affording the greatest gratification to the members attending. The district visited was Wilts., Devon, and Cornwall. From the appreciative remarks of the members, it does not seem likely that the generous reception accorded the society on this its first visit to the West Country will be readily forgotten.

The Hughes Recorder.—The Post Office authorities are reported to be experimenting between London and Liverpool with a view to introducing the Hughes recorder as a substitute for the Morse instrument in the sending of newspaper messages. The Morse instrument is excellent for newspaper work, for it permits of as much as 400 words being sent per minute. The advantage of the Hughes instrument is that the message is typed, whereas the Morse message is flimsied for newspapers.

New York Electrical Work.—The report of the Department of Public Works in New York City for the quarter ending June 30, states that during the quarter considerable activity was shown in the lighting of the city. In the public streets, parks, and places 134 new gas lamps and 400 new electric lamps were placed and lighted, and 1,390 gas lamps were replaced by electric lamps. There are now 24,011 gas lamps, 2,275 electric lamps, and 152 naphtha lamps in use. The report also shows that seven and one-third miles of gas mains and seven and a half miles of electric subways were put down.

Door Furniture.—We have received a pamphlet containing a copy of some excellent photographic illustrations of work in door furniture and electric light accessories, made by Messrs. R. Crittall and Co., of 34, North street, Manchester-square, W. Among the varieties shown are different types of door handles, lock and finger plates, shutter knobs, lock case staples, lock cases, panels, grilles, etc. Special attention is, however, directed to the ornamental covers for switches and cut-outs, and which are of very artistic design. The pamphlet should be inspected by electric light contractors and others interested.

A Congress of Inventors.—It is announced that a congress of inventors and those interested in patents and trade-marks will be held in Chicago during the week commencing Monday, October 2, under the direction of the American Association of Inventors and Manufacturers, and in connection with a committee of the World's Congress Auxiliary of the Columbian Exposition. A large number of well-known men have promised either to attend and read papers or to prepare papers on different subjects relating to inventions and patents. Among the latter will be one by Dr. R. J. Gatling, president of the association.

Electric Fire Alarms.—The thin red pillars that stand at prominent places about our streets fulfil on the whole a most useful service, provided always that it is not a drunken vagabond or knave who rings the alarm, and also that the electric circuit is in good order. In cases of emergency, however, it is to be feared that the average citizen would not know just where to find the electric fire alarm, and a suggestion shortly to be carried out in New York is worthy of adopting at home also. This consists of an enamelled iron sign, with black letters on a white ground, fixed in every street to show the direction and distance of the nearest fire alarm.

Converters.—The Court of Orleans has given judgment in the action for infringement between Messrs. Zipernowsky, Déri, and Blathy on the one hand, and the Compagnie Internationale d'Electricité de Tours on the other. The Civil Tribunal of Tours declared in August, 1887, that the Gaulard and Gibbs transformers did not infringe the Zipernowsky transformers, but the Court of Orleans has now reversed that decision. The Court has decided that the Compagnie Internationale had infringed the patents taken out on March 20, 1885, and April 21, of the same year, by Zipernowsky, Déri, and Blathy, and has ordered them to pay damages, and confiscated 18 transformers at Tours.

Telephony.—The *Pall Mall Gazette* of yesterday states: "Mr. Arnold Morley is, we believe, to be pressed to divulge to the House of Commons the terms upon which he is about to convey to the private telephone companies the monopoly of supplying telephonic services to London and the larger provincial towns. It is high time, in the interest of the traders, that the present exorbitant charge in London of £20 per annum should be reduced to £5 or £6; and the representatives of commercial London in the House are anxious that the Government shall not be committed to any continued toleration of the present excessive charges. If the Postmaster-General concludes the contracts without taking the traders in the House into his confidence there will be a great outcry."

An Electric Piano.—At the Bristol Industrial Exhibition an electric piano is shown. The piano, according to a local paper, is so constructed that a current of electricity passes through the body of the performer while both hands are on the key board. The regulating switch enables the performer to cut off the current altogether, or to vary its *strength* at will. The arrangement does not affect the action, tone, or touch of the instrument. The current is supplied by dry cells. It is said that the performer, after long practice with this hygienic arrangement, may arise without feeling the usual fatigue and cramp. The keyboard is practically the only part of the instrument that is different in appearance from ordinary pianos, the difference being due to the metal faces of the keys.

Transformers.—A new catalogue has just been issued by the Leeds and London Electrical Engineering Company, Limited, of 15, St. Helen's-place, Bishopsgate-street, E.C., who are the concessionaires of the Lowrie-Hall system of generation and distribution of electricity. The Lowrie-Hall converter, which has been adopted in various central stations, is made in sizes ranging in power from 1 e.h.p. to 50 e.h.p., and the standard sizes are for transforming current at 2,000 volts or 1,000 volts to 100 volts, and 2,000 or 1,000 volts to a voltage of 50. The catalogue contains engravings of and text referring to large and small converters, converter cases, main fuses for stations, high-pressure fuses and frames, main switches, regulators, arc lamp switches, surface and junction boxes, etc.

Electric Hoists.—Nine electric hoists of the drum and winch head type have, says the *Engineering News*, been in use for more than two years on the wharves of Sanderson and Sons, at Brooklyn, which are used by the Wilson line of Transatlantic steamers. Each hoist is equipped with a General Electric 10 h.p. bipolar motor. When the hoists were first put in there was great opposition on the part of the workmen, and the owners themselves were somewhat doubtful as to the success of their venture. Experience has shown, however, that the electric hoists have many points of advantage over the steam machines which they superseded. In the matter of repairs, it is stated that the total expense for repairs on the nine hoists since they were erected, although they have been in daily service, amounts to less than £5, or an average annual expense of, say, 6s. per hoist.

The Azores Cable.—The cable from Lisbon to the Azores was set in operation on the 27th ult., at the submarine cable station at Carcavellos. The King, the Queen, and other members of the Royal family, the Prime Minister, and the Ministers of Public Works and War took the leading parts in the ceremony, which began with the exchange of various congratulatory messages between the King and Ministers and the leading authorities at Fayal, where the first connection of the cable has been made. After visiting the establishment of the British Submarine Company, the guests took luncheon in the large grounds of the company. Squadrons of cavalry were drawn up in the grounds, and several bands played at intervals. The negotiations have been carried on for some 20 years for laying this cable, and finally, after a keen competition last year with the French company, who secured the concession and allowed it to drop, it was given to the British company.

An Enterprising Village.—Probably none of our readers have ever heard of a place called Granville: for one thing it has only some 1,300 inhabitants, but in the State of Ohio is well known as an educational centre. We call attention to it in this place, not for the university or colleges, but because the municipality runs its own street arc lighting plant, and also because the place is connected with the chief town of the county—seven miles distant—by means of an electric railway running 20 trains daily between the two places. The dividing line between railroads and tramways would seem to become a very shadowy partition, when such enterprises as the above are successfully worked; and there should be hope yet for electric

traction even in this country if too many restrictions—legislative and financial—are not put upon it.

New Submarine Boat. — There has just been launched at Toulon a new submarine boat which is of greater dimensions than the "Gymnote" and the "Goubet." The new boat, which has been named the "Gustave-Zédé" in memory of the late naval constructor, M. Gustave-Zédé, has a displacement of 236 tons, and its machinery develops 720 h.p. The principle of working has been copied from the Whitehead torpedo. The act of immersion is effected by the operation of a horizontal rudder, which is put into action when the boat is travelling, and as soon as the machine stops the boat rises to the surface. The motive power is furnished by accumulators. At the launch the boat dived twice, and finally came to the surface with its equipment of 11 men standing on a platform. The boat was subsequently taken into the arsenal.

Electrical Work in Railroad Shops.—The recent putting on short time of nearly 16,000 men at the London and North Western Railway Company's Crewe works affects, of course, the electrical department also. Probably it will be news to our readers that there is such a branch of the company's establishment, apart altogether, that is, from the signalling and telegraph service. Some very good dynamos and motors have been made at Crewe, of course for employment in the company's work—either in the shops for power and lighting, etc., or outside, say, for instance, hotel, office, and warehouse lighting, and so on. When we last visited the works, a few months ago, there were several well designed machines to be seen in operation supplying current at different points for light and power (electric crane driving, *e.g.*), and though not highly painted or polished, they had a very solid appearance, as though they might be run safely for months at a time without overheating, even with a full load and rather more.

Underground Wires.—There has this week been a terrible cyclone in Georgia, resulting in the breakage of many overhead telegraph wires and interruption to communication. In New York great havoc was played among the telegraph wires between midnight and eight o'clock on Tuesday morning, when New York became virtually isolated from the rest of the country. The tide in the North River was so high that the water covered the telegraph wires. This would not have happened if the wires had been placed underground, as in Germany, where the cue in this direction was given to the Germans during the Franco-German War. The first lines laid underground there were military lines between Metz and Strasburg and the other fortified centres, and now the telegraph system of Germany stretches to almost every village from the capital. It is the work of Dr. von Stephan, head of the Imperial Post Office, who has laboured at the service since 1876. The same department works both the telegraphs and the telephones, the latter being carried on at a very low rate.

Tesla Out-Tesla'ed.—We are waiting with some degree of impatience the receipt of information with respect to a wonderful performance that was announced to take place at Cleveland, Ohio, a fortnight ago. Mr. J. E. de Leon—styled "the young electrician of Buffalo, and possible rival of Edison" (!!)—was, on the 13th ult., to give a notable exhibition at Forest City Park. A modest advertisement sets forth that he "handles the current with perfect ease and safety, walking on a bare wire charged from the arc lighting circuit, which is powerful enough to kill an ordinary man, his body meanwhile being brilliantly illuminated by the current which is conducted through it." Mr de Leon—who might safely be called Cœur de Leon—is a dangerous man, unless his morals are of the highest order, for evidently the electrocution system would fail in his case, and he might kill, murder, or slay with impunity. Stay, though; they are said to give morphine first, and that is possibly an antidote to Mr. de Leon's "apparatus, entirely of his own invention and construction, exhibiting inventive genius of a high order."

Excitability of the Muscles.—It is generally admitted that the electrical excitability of the muscles disappears a short time after death. This is true when the contraction of the muscles as a body is taken to determine the excitability, but it is insufficient to disclose very slight movements. M. d'Arsonval has for some years used for the purpose of studying the vibrations of the muscle a microphone, with magnetic regulation, termed a myophone. The myophone gives results before the excitation is sufficient to bring about contraction in a mass, and the intensity of the sound is greater if the muscle is strained by a spring. By the aid of this apparatus, M. d'Arsonval has found that the excitability of the nerves may continue for several hours after death. In order to prove this it is sufficient to attach the Achilles tendon of a rabbit to the myophone, and to excite the sciatic nerve by means of an intermittent current 50 or 100 times per second. Experiments in this direction show that the nerve can act upon the muscle without there being any apparent contraction, but simply molecular vibration, and that the death of the nerve takes place much slower than was believed.

Dangerous Rivals.—There has not so far been any serious trouble in this country arising out of competition between various trades for the work involved in carrying out an electrical installation; bricklayers, carpenters, and other artisans have left "electricians" and wiremen severely alone, thinking, perhaps, that a very large quantity of skill and information must be required for success in such a sphere of toil. On a huge insurance building now under erection in New York there is, however, at the present time a lively dispute going on between the wiremen and bricklayers as to which class of workmen is entitled to cut the holes in the brick walls through which the wires are to be brought. The respective unions have taken the matter into consideration, and since the work is not being done under contract the superintendent in charge of it has stopped operations, intending to allow the men to fight out the question themselves. It would be interesting to know whether the wiremen expect that bricklayers, if allowed to cut the walls, would thereby grow skilled enough to take an "electrician's" job, or whether the bricklayers consider that a wireman would find time enough and an inclination to spill mortar and hold a plumb-line with the "best of 'em." His power to make a good wire joint in that case might well be questioned.

An Electric Dredge.—An "electric" hydraulic dredge is proposed by Mr. E. J. Foord, to be used on portions of rivers where it is at present impossible to work by any appliance now employed. A New Zealand contemporary, the *Insurance, Mining, and Finance Journal*, states that the ordinary bucket and ladder dredges cannot, by reason of the heavy expenses entailed in repairs and the necessity of heavy and ponderous machinery required in such cases, work effectively on rough rocky bottoms or where the depth exceeds, say, 35ft. or 40ft. The plans proposed by Mr. Foord show several departures from any appliances at present in use for this description of work, and provide for any depth, say up to 60ft., being worked without trouble. The difference in the number of working parts in the two classes may first be noticed. On one of the dredges in use at Waipori or on the Clutha or Shotover

each ladder that carries about 40 buckets has nearly 700 working parts that cannot be oiled, and that are exposed to the action of water, sand, and dirt. These require almost constant attention and frequent renewal, and average a cost of 24s. a day to keep in repair. The steam-engine is also an expensive item, costing in many cases over £4 per day, and sometimes even more than this sum. These two items alone run away with the respectable sum of £1,635 for a year's work. By the proposed electric system £550 will do the same amount or even more work, as less repairing means more time to devote to paying work, and will leave a saving of £1,135.

Thinks it Doesn't Pay.—The current idea throughout the two hemispheres may be taken as certain that Edison has made, not a small, but a big fortune out of his inventions and discoveries. Probably his financial supporters have done so; indeed, that might be more confidently asserted. The great man's own expressions are to the effect that he is tired of it, and that it does *not* pay. These are his words: "I am not going to have anything to do again with anything that I have to get a patent on. Pioneering in any line of invention doesn't pay. For 20 years I have been fighting for 30 or 40 patents that I own. Out of all these I have been sustained in but two. The rest will probably be sustained 10 or 15 years after the patent rights expire. It is not that the patent laws are not right; it is because the practice in the courts is such that an inventor can get no satisfaction except by some defendant paying the inventor, or by sheer accident. This inventing business is a poor trade anyhow. If a man gets money it goes in litigation. The capitalists he has to fight have money enough to hold out for years where he can stand the expense for days only. Then the capitalists who have brought his invention into practical use, and paid the inventor in the corporation's stock, always slice from his share when they get into litigation on the score of patent rights, until finally his stock is all gone, and either one set of capitalists or the other have got the advantage of his mental toil and years of hard labour." In all which there is a large amount of truth and sound common sense, especially if the unfortunate man is a real inventor and not merely an adapter of other people's ideas.

The British Association.—The meeting of the British Association will commence at Nottingham on Wednesday week, the 13th inst., under the general presidency of Dr. Burdon Sanderson. The following gentlemen have accepted the positions of presidents of the different sections: Mr. R. T. Glazebrook, Dr. Emerson Reynolds, Mr. J. J. H. Teall, Rev. Dr. Canon Tristram, Mr. Henry Seebohm, Dr. J. S. Nicholson, Mr. Jeremiah Head, and Dr. H. Robert Munro. Amongst the subjects to be considered by the sections are: Electrical standards, meteorological observations on Ben Nevis, the application of photography to meteorology, calculation of tables of certain mathematical functions, recording direct intensity of solar radiation, wave-length tables of the spectra of the elements, an international standard for iron and steel analyses, the direct formation of haloids from pure materials, action of light on dyed colours, the discharge of electricity from points, comparing and reducing magnetic observations, optical constants of lenses, ultra-violet rays of the spectrum, meteoric dust, and the rate of increase of underground temperature. Among some of the other subjects which will probably be introduced and discussed will be the following: In Section A (mathematics and physics) the question of the national physical laboratory, of the central publication of physical papers, of magnetic and other units, and of mechanical connection between ether and matter will probably be raised. In Section G (mechanical science), Mr. Keep (of Messrs. Manlove, Alliott, and Co.) will discuss thermal storage in connection with the utilisation of refuse, and Mr. Warner is expected to describe destructors.

Electric Quackery.—The "medical electrician" has come up very prominently into notice at the World's Fair, and it won't be his fault if a battle does not rage over his mercenary and sordid carcase. The administrative officers of the exhibition made a very big mistake when they allowed such abominations as "medical belts" to occupy any space at all, but probably they were not blind to the financial ability and resources of electric quacks. Now that a jury of competent men—who know respectable science when they see it—have begun to consider the exhibits for report and awards, there is a natural reluctance on their part to touch the unclean thing; but the American electrical journals are—very rightly—loud in their denunciations of such weak-kneed policy, and call upon the officials to insist upon a full examination of all exhibits as a matter of common fairness. It is to be hoped, says New York *Electricity*, that the jurors will sit on these frauds, and *sit hard*. So far as the fakirs themselves are concerned, they have had the hardihood to ask for these judicial reports, and have induced some of their fellow-exhibitors to sign the following choice petition, addressed to Prof. Barrett, the head of the Electrical Department: "Dear Sir,—There having been more or less said against the electric belts exhibited in this building, and referring to them as fakes, we, the undersigned, respectfully request that said belts be submitted to a jury for them to test same for voltage, amperage, and internal resistance. We ask this to sustain you in your action in giving them a space, and also in justice to themselves as exhibitors. There are many electrical appliances and belts that are fakes, from which no current can be obtained, and those that do not have merit should be known, especially the exhibitors that you have admitted in this Electrical Building in the World's Fair." As to which it might be said—*Arcades ambo.*

Electricity on a Pyramid.—In his autobiography the late Sir W. Siemens relates an amusing anecdote. An Arab called his attention to the fact that when at the top of the Pyramid of Cheops, when he raised his hand with fingers outspread, an acute singing note was heard, the sound ceasing as soon as he let his hand fall. "I found his assertion," he writes, "to be true. As soon as I raised one of my own fingers above my head, I felt a prickling in the fingers. That this could only be caused by an electrical phenomenon was proved by the slight electric shock felt on trying to drink out of a wine-bottle. So I wrapped a full bottle of wine that I had with me in damp paper, and thus converted it into a Leyden bottle, which was soon strongly charged with electricity by the simple device of holding it high above my head. The Arabs had already become distrustful on seeing small lightnings, as it were, issue from the wine-bottles held up by myself and companions, and now held a brief consultation. Suddenly, at a given signal, each of my companions was seized by the guide who had led him up, who now tried to force him to go down again. I myself was standing at the very top of the pyramid, when the sheikh of the Arabs came to me and told me, through my interpreter, that the Arabs had determined that we were at once to leave the pyramid, because we were practising magic, and it might damage their chance of their earning a living. On my refusing to obey orders, the sheikh caught hold of my left hand. I had awaited this moment, and held up my right hand with the bottle in the attitude of a magician, afterwards lowering it slowly towards the point of the sheikh's nose. When quite close

to that feature I felt a violent shock run through the bottle to my own arm, and was certain that the sheikh must have received the equivalent. At any rate, he fell speechless on the stones, and a few anxious moments passed before he rose suddenly with a loud cry, and sprang down the gigantic steps of the pyramid with long strides. The Arabs seeing this, and excited by the sheikh's constant cries of 'Magic! magic'' released my companions and followed their leader, leaving us complete masters of the pyramid."

Edinburgh and Telephony.—The Glasgow Corporation have asked the Edinburgh Town Council to support the application of the former to the Postmaster-General for a license to establish a telephone system. This was considered at a meeting of the Edinburgh Council on Tuesday. Lord-Provost Russell said that in sending this matter to his committee, the Council ought to give the committee powers to enquire into the whole subject. They had seen by the newspapers that the Postmaster-General had given a rather evasive answer to the Glasgow Corporation. He thought that Corporation deserved their thanks for bringing this question to an issue. A Special Committee of the House of Commons had recently reported that telephone undertakers, which practically meant one company, were to have the right to go under the streets. They felt this bad enough in connection with their own trusts, but if they had to do with a body which was hostile to them, and which had led them to considerable expense the other day in opposing them before the House of Commons, they would have many a controversy if they had to fight them every time they opened a street and spoiled it. It seemed to him the Government, by their committee, were forcing municipalities to consider whether they should take up the question of taking over the telephone service or not. They must investigate and see where they were. If the Postmaster-General refused the application, and made a fresh agreement with the telephone companies, it would mean that all the corporations in Scotland should appeal to the Government; they could not submit to the telephone companies destroying the streets. He moved that the matter be remitted. Bailie M'Donald, in seconding, said he would like powers given to the committee to support the Glasgow Corporation in preventing the company from taking possession of the streets. The Lord Provost said the Council might be willing to give the committee powers in handling the question in Parliament. After further conversation the matter was remitted to the committee.

Telephony at Glasgow.—The Municipality of Glasgow, having applied for a license to establish a telephone exchange within that city, has received a reply stating that the Postmaster General observes that the application refers to a recommendation of the recent Joint Committee on Electric Powers, and he thinks it right to inform them that he has received a communication on the subject from the Association of Municipal Corporations. The question whether measures shall be taken, and, if so, what measures, to give effect to this recommendation of the joint committee, must, he says, engage the very careful consideration of her Majesty's Government, and the association has been informed that no final step will be taken until they have been afforded an opportunity of expressing their views. In view of the intimate relation between the question of fresh licenses for telephone exchange business and that of statutory powers for laying telephone wires underground, the Postmaster-General does not feel that he can at present arrive at any decision on the application from Glasgow. Not content with this reply, a deputation of the Glasgow Corporation had an interview with the Postmaster-General on Wednesday evening. After hearing the views of some of the members of the Corporation, Mr. Arnold Morley, in reply, said that the Government would not at all interfere with the freedom of municipal enterprise with regard to any matters it could legitimately control for the public interest. The telephone, however, was not a part of municipal business, but belonged to the telegraph system, which was conducted by the State. It was not confined to the municipal area, like water, gas, or tramway works. In continuance of the policy of the late Government, he was now engaged in purchasing the trunk lines of the telephone system, and until that was completed it was impossible to consider the question raised by the present application. The movement might possibly develop into the Government taking over their entire management, but any step taken in advance in local districts would complicate matters. He was strongly in favour of further powers being given to the municipalities to manage affairs which were strictly municipal, but he could not enter into further details on the question raised by the deputation until the agreement as to the trunk telephone lines had been finally settled.

Mexico and California.—According to the *Scientific American*, electrical enterprise is very progressive in Mexico. That this is so we are in a position to know, but the English work in the matter has been carried on very quietly, and those engaged in it have requested silence. We are unable, then, to do more at present than to quote our contemporary, which says: "Among the notable industrial enterprises recently inaugurated in Mexico is the electric lighting of the city of Guadalajara. The plant utilises the famous Juanacatlan waterfalls, which are situated about 18 miles from Guadalajara. The Thomson-Houston generators are actuated by Leffel turbines, the head of water being 58ft. Three turbines of 550 h.p. are used. The dynamos for arc lighting have capacity each for 50 arc lights of 2,000 c.p. The current strength is 10 amperes, and consequently the maximum voltage is 2,500. The incandescent dynamo consumes about 750 h.p. and yields approximately 350 amperes at 1,000 volts, or say 350 kilowatts. The voltage is increased from 1,000 to 5,000 volts by means of 10 step-up transformers. They transform the energy of the dynamo at an efficiency of about 98 per cent., delivering to the line, therefore, 98 per cent. of the energy supplied them and at five times the pressure. The high-pressure incandescent circuit is reduced to 1,000 volts by step-down transformers at Guadalajara, 17 miles from the source of electricity. The installation of the San Antonio Light and Power Company, of Pomona, California, possesses many feature of interest. The current is carried 28 miles under the enormous pressure of 10,000 volts. The generators are of the standard 120-kilowatt, 12-pole, 1,000-volt Westinghouse alternator, which delivers current at 7,200 alternations on being driven at 600 revolutions per minute. The generators are coupled direct to Pelton waterwheels, the head being 395ft. The 1,000-volt current is taken to the switchboard and from there to the bank of step-up transformers, from which the current is delivered under a pressure of 10,000 volts. One circuit is carried to Pomona, 15 miles, and the other to San Bernardino, 28 miles away. The wire used is No. 7 B. & S. hard-drawn bare copper wire, and is carefully supported on poles by insulators specially designed for this plant. A potential of 9,500 volts is received in Pomona and 9,000 in San Bernardino. The pressure on the city lines is maintained at 1,000 volts."

ALTERNATE-CURRENT TRANSFORMER DESIGN.

BY R. W. WEEKES, WHIT.SCH., A.M.I.C.E.

(Concluded from page 55.)

Alteration of Efficiency with Frequency.—The selection of the most economical frequency for alternate-current working from supply stations is influenced by so many different considerations that the present want of uniformity in this respect can hardly be a matter for surprise. It is most important that each company using the alternate-current system should arrange all their generating plant to work at the same number of cycles per second. If the prime movers are suitable, the alternators can then be run in parallel with each other, and even if the engine will not allow of parallel running, this uniformity in the frequency given by the different alternators in the same station is advantageous. Beyond this the matter has been largely left in the hands of the manufacturers. So we find that in America the high frequency of 133 periods per second has been extensively used because a large manufacturing company adopted it as their standard. In England, the practice is to use generally frequencies between 75 and 100, whereas on the Continent much lower values have been successfully adopted. It is out of the range of the present articles to consider the whole grounds for and against either extreme in the adoption of a standard frequency. Roughly, the higher values tend to slightly reduce the first cost of the generating plant, and the use of motors is as yet only commercially possible where low frequencies are used. Whichever may be universally more economical, the fact remains that transformers have to be used, and it is the effect on the economy of the transformer that we have to consider.

From equation (1) the potential difference, as measured by a Cardew voltmeter, at the terminals of a transformer on open circuit is

$$e = 4{\cdot}45 \text{ F } \tau \, n \, 10^{-8},$$

and F, the total flux, may be written $\mathfrak{B}\, a$ where $\mathfrak{B}$ equals the maximum induction, and a equals the cross-section of the iron core. Hence

$$e = 4{\cdot}45 \, \mathfrak{B} \, a \, \tau \, n \, 10^{-8}.$$

With a transformer having a certain transforming ratio, say, 2,000 / 100 volts, the voltage, e, required on the secondary will be the same whatever the frequency of the alternating current supply. This ensures that e shall be a constant quantity however the frequency may vary on different supply mains. We may therefore consider e as constant, and the quantities a and τ on the other side are also constants for any given transformer. Hence, if n changes, there must be an inverse change in $\mathfrak{B}$ to keep the E.M.F up to the same value, or, in other words, $\mathfrak{B}\, n = \mathfrak{B}_1 \, n_1$, where $\mathfrak{B}_1$ n_1 are the new values of the induction and frequency respectively. Hence, in the transformers designed above for 100 $\sim$ the induction required would be doubled if the frequency were dropped to 50 $\sim$. This alteration in induction alters the value of the iron losses, and hence affects the efficiency of the transformer

The subject of the loss in iron wire and plates when subjected to a magnetising force which varies has been a source of many investigations of late years. The conclusions arrived at by the many able experimentors on this subject are: first, that the hysteresis loss in the iron for any given induction is directly proportional to the number of reversals; second, from the many curves obtained it is found that the results are fairly represented by an equation containing $\mathfrak{B}$ to the 1·6th power. Hence the loss in hysteresis only may be expressed by the equation:

$$W_H = a \, n \, \mathfrak{B}^{1{\cdot}6} \quad . \quad . \quad . \quad . \quad . \quad (5)$$

where W_H = the watts lost per pound of iron;
a is a constant depending on the iron used;
n = the frequency;
$\mathfrak{B}$ = the maximum induction.

The other part of the iron loss is that due to Foucault currents in the iron plates

The determination of formulæ for calculation of these losses in plates requires some elementary calculus, and certain assumptions as to the path taken by the current have to be made. It will be sufficient to take the generally accepted formula for iron plate, which, when reduced to watts per pound of iron, becomes, roughly

$$W_F = 5 \, (t \, \mathfrak{B} \, n)^2 \, 10^{-9} \quad . \quad . \quad . \quad . \quad (6)$$

at 100deg. F., where t = the thickness of the plate in inches and $\mathfrak{B}$ and n have values as above. Now, for any given transformer the square of the thickness of the plates may be merged into the constant, and the formula becomes

$$W_F = b \, (\mathfrak{B} \, n)^2,$$

where b is a constant. Hence the total loss is given by

$$W_H + W_F = a \, n \, \mathfrak{B}^{1{\cdot}6} + b \, (n \, \mathfrak{B})^2.$$

As n occurs in different powers in the two terms on the right-hand side of this equation, it will be readily seen that any curve drawn for the total iron losses for a given frequency cannot be used at any other frequency. It is, however, quite possible by careful experiments to verify the equation given above. This can best be done by taking power readings of the iron losses when the frequency is varied very considerably. Then the different set of results can be analysed by simple algebra. This can be more readily done with plates of greater thickness than those used in ordinary work, as in that case the expression for the eddy currents is a larger proportion of the total loss. The approximate truth of this formula and the corresponding expression for the eddy-current loss per pound of iron being established, we can proceed to divide the curve of iron losses, Fig. 4, into its two components. To do this, the loss in watts per pound for inductions varying from $\mathfrak{B}$ = 8,000 to $\mathfrak{B}$ = 1,000 must be calculated from (6), and the figures obtained when subtracted from the ordinates of curve, Fig. 4, leave the hysteresis loss per pound at 100 cycles per second. Thus at $\mathfrak{B}$ = 6,000 for 10 mil plates we have

$$\begin{aligned} W_F &= 5 \, (t \, \mathfrak{B} \, n)^2 \, 10^{-9} \\ &= 5 \times (\cdot 01 \times 6{,}000 \times 100)^2 \times 10^{-9} \\ &= 5 \times 6{,}000 \times 6{,}000 \times 10^{-9} \\ &= \cdot 180 \text{ watt per pound.} \end{aligned}$$

Now the ordinate on Curve 4 when $\mathfrak{B}$ = 6,000 is 1·70. Therefore the hysteresis loss alone is 1·70 – ·18 = 1·52 watts per pound of iron.

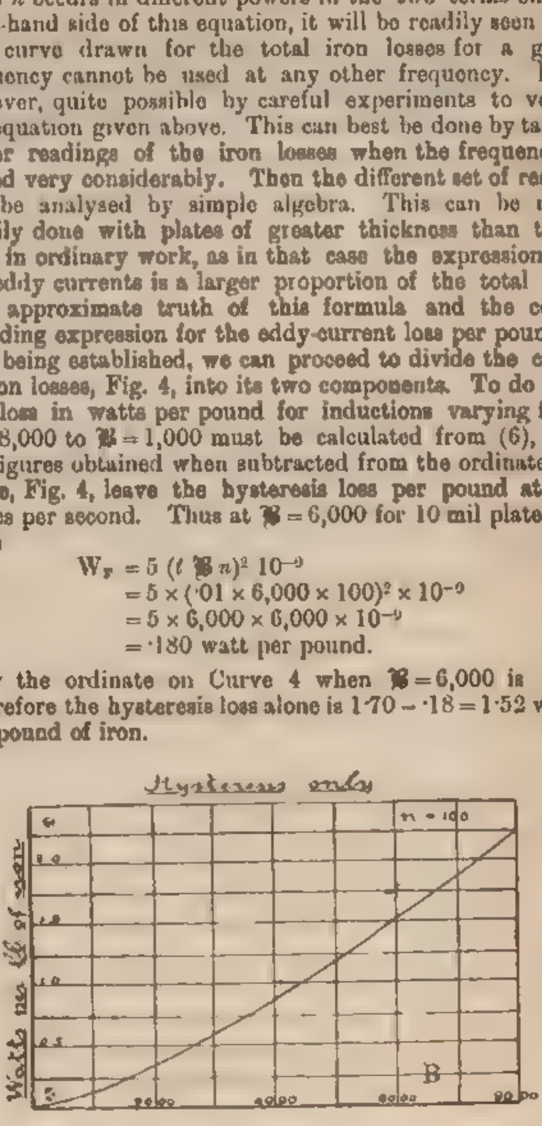

Fig. 25.

Doing this for all the points, and plotting the results in a curve as before, we obtain Fig. 25, which gives the loss per pound of iron due to hysteresis only, at 100 $\sim$. From this the losses at other frequencies can be obtained by simple proportion. It will be found on trial that the curve thus obtained is not quite in uniformity with the equation of $\mathfrak{B}$ to the 1·6th power. This is due to some qualities of the iron from which the original results were obtained. To explain fully the method of working with this curve it will be well to take the design No. 1 and to calculate the iron losses for that transformer when working at frequencies of 50, 75, 100, and 130 respectively.

We have from the table of results that for n = 100 $\mathfrak{B}$ = 3,580 at the normal voltage; now $n \, \mathfrak{B} = n_1 \, \mathfrak{B}_1$, so that

$$\mathfrak{B}_1 \text{ for } n_1 = 50 = \frac{3{,}580 \times 100}{50} = 7{,}160.$$

In the same way as n_1 = 75

$$\mathfrak{B}_1 = \frac{3{,}580 \times 100}{75} = 4{,}800.$$

and at n_1 = 130, $\mathfrak{B}_1$ = 2,770.

We will in this case tabulate the results, as errors can then easily be seen and avoided. The fact that the hysteresis loss is directly proportional to the frequency now enables us to determine the total hysteresis loss in each of the above cases. Thus at $\mathfrak{B} = 7{,}160$ the loss per pound at 100 ⁀‿ is, from Fig. 25, 1·94 watts per pound. ∴ the loss at 50 ⁀‿ in 172·5lb. will be

$$W_H = \frac{1{\cdot}94 \times 172{\cdot}5 \times 50}{100} = 168 \text{ watts.}$$

Table of Iron Losses and No Load Currents for Shell Type Six Kilowatt Transformer, Design (1), at Different Frequencies.

Frequency.	50	75	100	130
$\mathfrak{B}$	7,160	4,800	3,580	2,770
Hysteresis watts	168	146	133·8	124
Foucault watts	11	11	11	11
Total loss	179	157	144·8	135
μ	2,650	2,300	1,960	1,680
i_μ	·127	·098	·0858	·0772
i_H	·089	·078	·0724	·0675
i	·155	·123	·112	·1025
Iron loss per cent.	2·98	2·62	2·42	2·25
i per cent.	5·16	4·16	3·72	3·42
Power factor	·57	·63	·648	·658

In the same way for $\mathfrak{B} = 4{,}800$ and $n = 75$,

$$W_H = \frac{1{\cdot}125 \times 172{\cdot}5 \times 75}{100} = 146 \text{ watts.}$$

The rest of the values of W_H calculated in the same way are 133·8 for $n = 100$, and 124 watts for $n = 130$.

The Foucault loss is got from the formula (6)—*i.e.*, watts per pound $= 5\,(t\,\mathfrak{B}\,n)^2\,10^{-9}$.

In this transformer 10-mil plates were used, and the iron weighed 172·5lb.

Hence, $W_F = 172{\cdot}5 \times 5 \times (\cdot01 \times 7{,}160 \times 50)^2 \times 10^{-9}$.
$= 11$ watts at 50 frequency.

But we saw above that $\mathfrak{B}\,n$ was always a constant if the voltage at the terminals of the transformer was not varied. So the eddy current loss must also be a constant for all frequencies, as these two quantities are the only variables in the equation used above. Filling up the list, the total iron loss in each case can now be obtained by addition. It will be immediately observed that this increases rapidly with a decrease of the frequency. By halving the value of n, we have in this transformer increased the iron losses by some 25 per cent. Hence, if the transformer was designed to the heating limit at a frequency of 100, it would get too hot when placed on a circuit supplied at 50 frequency. This change in the iron loss is more marked in transformers using a higher induction than in the present design. To complete the list, we now require to find the exciting current at the different frequencies. The values of μ for each induction can be at once taken from the curve Fig. 5. Then i_μ from (2) $= \dfrac{\mathfrak{B}\,l}{\mu\,\tau_1 \times 1{\cdot}76}$. As four values have to be calculated and part of the right-hand side, $\dfrac{l}{\tau_1 \times 1{\cdot}76}$, is common to all cases, it may conveniently be worked out separately.

In this transformer, l, the mean length of the iron circuit was 123cm. and $\tau_1 = 1{,}490$,

therefore $$\frac{l}{\tau_1 \times 1{\cdot}76} = \cdot0468\,;$$

and $$i_\mu = \frac{\mathfrak{B}}{\mu} \times \cdot0468.$$

Thus at $n = 50$, $\mathfrak{B} = 7{,}160$, and $\mu = 2{,}650$,

$$\therefore i_\mu = \frac{7{,}160}{2{,}650} \times \cdot0468$$

$$= \cdot127 \text{ ampere.}$$

The rest can be worked out in exactly the same way. The values of i_H are obtained by dividing the total iron loss by the voltage on the primary winding, which in this case was 2,000.

The magnetising current $i = \sqrt{i_H{}^2 + i_\mu{}^2}$, so in the first case $$i = \sqrt{\cdot089^2 \times \cdot127^2}$$
$\cdot155$ ampere.

Completing the other values in the same way, it will then be better for reference to add two more lines, showing the iron loss and magnetising current respectively in percentages of the full-load values. The ratio of these two gives the power factor, which will be seen to fall with the frequency. This is not always so, but depends largely on the shape of the μ curve of the iron used.

The general conclusions from this investigation are briefly as follows: When the frequency at which the transformer is used is decreased, the loss in iron is increased, and there is consequently a fall in the efficiency of the transformer. (It must be remembered when considering the loss in the iron of a transformer, that although the loss may be a comparatively small percentage of the maximum output, it is a large percentage of the average load. Thus, while an increase of 25 per cent.—*i.e.*, from 2·42 to 2·98 per cent.—does not appear much, it may make the difference between profit and no profit in the central station accounts.) Also the larger iron loss will increase the final temperature of the transformer. So, for low frequencies, more cooling surface should be provided. In other words, a larger transformer is required. This, of course, will raise the cost of the instrument for a given output. On the other hand, a transformer designed to have a good efficiency at a low frequency can be used more economically at higher frequencies, but the cost of manufacture will then be the prohibitive factor.

Quality of Iron.—This is the indeterminate quantity which causes uncertainty in the manufacture of transformers. Every batch of iron received should be kept separate, and the tests of the transformers made from it then give a ready check on any falling off in the quality. The curves given (Figs. 4 and 5), which have been used in all the designs above, were taken from a transformer actually made. The iron was a better quality than the average brands of plate, but was by no means the best that can be obtained. With careful selection, iron can be found with which the losses per pound come out quite 30 per cent. below those given in Curve 4. It is in the permeability curve that the greater difference is noted with these superior qualities of iron. This curve, then, rises much more rapidly at low inductions, and the permeability throughout may be some 80 per cent. higher than the values given in Curve 5. The higher permeability reduces the current required to magnetise the iron, and consequently the power factor is increased. On referring to Dr. Fleming's list of tests, it will be seen that in one case he obtained a power factor as high as ·92. A special brand of mild steel is said to be used in this transformer, which must have a very high permeability to account for such a power factor.

Transformers for Different Methods of Supply.—The transformers used in lighting individual houses are very seldom worked at full load, and the average load is so small that the heating effect of the current in the copper circuit may be almost neglected. The transformer should, of course, be able to stand the full current for some hours without undue rise of temperature. The all-day efficiency is then fixed by the iron loss, and but for the regulation the copper might be reduced to save first cost. The sub-station system of supply is now coming into more general use. In this system the consumers are connected on to a low-tension network, which is fed at different places by transformers in sub-stations. In this way, even if the whole of the transformers are left continuously on the mains, a much higher load factor is obtained, owing to the different classes of buildings supplied. That is to say, the average load is a larger proportion of the maximum load, and hence the transformer is worked more economically. To still further increase the economy, arrangements are made for reducing the number of transformers in connection with the main as the load diminishes. So in these transformers and in those used in power transmission on a large scale, the watts wasted in the copper form a good proportion of the total loss. As the heat generated in the copper is liable to [illegible] the insulation, it is advisable in the large trans[illegible] for central-station work to keep the [illegible] copper lower than in small t[illegible] installation work.

ON THE TRANSMISSION OF ELECTRIC SIGNALS THROUGH SPACE.*

BY W. H. PREECE, F.R.S.

(*Concluded from page 184.*)

It is very necessary to be able to distinguish or separate these earth currents from currents due to induction, for they are very apt to give false effects and to lead to erroneous conclusions. This is easily done, if the instrument be sensitive enough, by making the primary current continuous when the earth current also becomes continuous, while induction currents are momentary, and are observed only during the rapid rise or fall of the inducing cause.

2. Electrostatic Induction.

When a body, A, is electrified by any means and isolated in a dielectric, it establishes an electric field about it. Lines of electric force are projected from it in every direction; and if in the direction of any of these lines of force there is placed another similar body, B, it is also electrified by induction. If B be placed in connection with earth or with a condenser, or with any large body, then the charge of the same sign as A is conveyed away, and B remains electrified in the opposite sense to A, and to the same amount. A and B are seats of electric force. They form a stress, and are the ends of a line of force. The dielectric between them is displaced or polarised electrically. It is in a state of strain, and remains so as long as A remains charged, but if A be discharged, or have its charge reversed or varied, then similar changes occur in B and through the dielectric separating them.

Fig. 1.

If A, Fig. 1, be a flat disc electrified positively and be placed inside a ring, B, then the ring becomes the termination of lines of electric force, and the sum of their terminal negative charges is equal to the whole positive charge of A. A may, in each of the above cases, be the section of a continuous wire or conductor forming part of a complete circuit.

Fig. 2.—During Charge.

The charge on A may be due to the electric force of a primary current, while in the secondary conductor, B, the displaced charge in flowing to earth establishes a momentary current whose direction and duration depends on the current of A, and on its rate of variation.

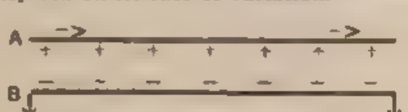

Fig. 3.—Steady Current.

The strained state of the dielectric and the charges on A and B remain quiescent so long as the current flows steadily; but if the primary current ceases, then we have secondary currents in each conductor, as shown by the arrows, and flowing until equilibrium is restored.

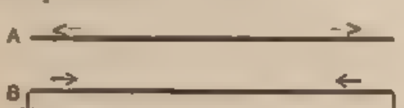

Fig. 4.—During Discharge.

The secondary currents due to discharge, flow in opposite directions at each end, and there is always some intermediate zero point.

* *Paper read at the Chicago Exhibition.*

It is thus easy in long circuits by observing their direction to differentiate currents of induction due to electric displacement from those due to electromagnetic disturbance.

The dielectric plays just as important a part in the electrical operations that occur as do the conductors. Its molecular disturbance cannot be neglected. It is subject to strain and variations of displacement in one direction, while it is permeated by a wave of energy in another direction—viz., in the direction of the primary current. In fact, it is a question much discussed at the present day whether the prime action in all current effects is not this wave or flux of energy passing longitudinally through the dielectric in the direction of its length, and that nothing whatever passes through the conductors, which are mere passive agents in the matter, wasting energy but not transmitting it.

There are two views of the formation and support of a current. The one following Faraday regards it as the continuous discharge of the contiguous charged molecules of the conductor, the action originating in and being propagated uniformly throughout the conductor. The dielectric plays only a secondary part. The other derived from Maxwell by Poynting regards a current as the consequence of the propagation of a wave of electrical energy through the dielectric in the direction of the line, and which reaches the wire from the exterior. The conductor plays a secondary part—it simply dissipates the energy conveyed by the dielectric. The current is set up on the

Fig. 5.

surface, and it penetrates the interior comparatively slowly, while its distribution in any given sectional area of the conductor is not uniform.

The truth lies probably in a combination of each view. The dielectric is as much an essential agent in the action as the conductor, and in each plane, perpendicular to the current, the charge and discharge of contiguous molecules, the formation of an electric field, the formation of a magnetic field, the flow of energy across this plane and parallel to the conductor, its dissipation as heat in the conductor, are all simultaneous and self-dependent, and equally concerned in the final result.

In a complete metallic loop the energy is propagated in the dielectric between the wires, it is dissipated in the wires, there are longitudinal waves propagated through the dielectric parallel to the wires, and there are other circular electromagnetic waves emanating from each conductor as a centre and flowing as a resultant in planes perpendicular to the wires. Thus there are lines of electric force, lines of magnetic force, and lines of energy flow. The first determine displacement, and are controlled by electrostatic capacity; the second determine electromagnetic disturbance, and are controlled by inductance; the third determine transformation of energy, and are controlled by resistance. Time enters into the consideration of the longitudinal speed of the energy flow through the system, of the electromagnetic disturbance through the dielectric at right angles to this flow, of the rise and fall of the current at each point of the circuit, of the character of the current, whether continuous or alternating, and, if alternating, of the frequency of the complete alternations.

The effects of electrostatic induction do not play an important part in the enquiry immediately before us, but they are of great consequence in considering questions of speed of signalling in submarine cables, and clearness of speech in long-distance telephony.

3. Electromagnetic Induction.

Magnetic force is that which produces or tends to produce polarisation in magnetisable matter—viz., iron, nickel

and cobalt—and electromagnetic disturbance in non-magnetisable matter and the other. It excites lines of magnetic force and becomes a stress. An electric current in a conductor is a seat of magnetic force. It establishes in its neighbourhood a magnetic field

The lines of force, Fig. 5, in this field are equivalent to circles in a plane perpendicular to the direction of the current, which, during the rise of the current in A, flow outwards, and during the fall of the current flow inwards, like the waves on the surface of smooth water when a stone is dropped into it, but moving with the speed of light. Thus any other linear conductor, B, placed in this field parallel to A, is cut at right angles to itself by these lines of force—in one direction as the current rises, and in the other direction as the current falls. The projection of lines of magnetic force through a linear conductor in a direction perpendicular to its length excites electric force in that conductor; and, if the conductor be continuous and form part of a circuit, it establishes voltage, and, therefore, a current in this secondary circuit. Now, the strength of this secondary current, C_2, depends on the strength of the primary current, C_1, on the rate at which it rises or falls $\left(\frac{dC}{dt}\right)$, on the resistance of the secondary circuit, r_2, on the distance which separates the two circuits, d, and on

FIG. 6.

the length of the inductive system, l. The direction of the secondary current everywhere is reverse to that of the primary during its rise and in the same direction during its fall.

If the two circuits are separate and independent, this action between them is called mutual induction; but if B be a part of the same circuit, A, it is called self-induction The amount of induction is dependent also on the magnetic elements present in the conductors and in the space between them. This is measurable in its own unit (which it is proposed to call "henry"), is called inductance, and is usually indicated by L or M, according as the question dealt with is self or mutual inductance.

EXPERIMENTAL INVESTIGATION.

Since 1885 I have had a vast number of experiments made to thresh out the laws and conditions that determine the distance at which these magnetic disturbances can be usefully evident. The instrument used to receive these signals has been generally the telephone, but many absolute measurements have been made with a very sensitive reflecting galvanometer. The judgment required to determine the relative intensity of sound in a telephone is a very variable and uncertain agent, even though many observers be utilised and the same experimenters perform with the same apparatus. But this does not apply to the observation of the limiting audible intensity of signals. The point where sound ceases is obtained with concordant and satisfactory results when the mean judgment of several observers using the same telephone is made use of. I never use less than three observers, and sometimes have employed as many as seven. By this means we observe by what I call the average normal ear.

I. To prove that the effects were due to electromagnetic induction.

Conductors of copper wire insulated with guttapercha were formed into quarter-mile squares, Fig. 6, and laid on a level plain at a distance of a quarter of a mile apart.

Arrangements were made for sending vibratory or alternating currents which could be broken into Morse signals by means of a telegraph key. Telephones were used as receivers, which transformed these signals into buzzing dots and dashes.

On closing the circuit in one square and sending signals, conversation could be readily held between the two operators by means of the Morse code. Now, obviously, earth conduction could play no part in this transmission of signals, for the squares were insulated throughout from the earth.

Next, in order to ascertain to what extent, if any, electrostatic effects were observable, one pole of the battery used was put to earth, and the further end of each square was disconnected.

Now, by this arrangement the mean electric force of one square was doubled, as compared with the former experiment, where the circuit was completed, but no effect was observed in the second square, either in the receiving telephone or with the reflecting galvanometer. The squares were even superposed at a distance of only 15ft. apart, the upper one being suspended on poles, and the lower one laying on the ground, but without any result. Hence, the effect observed in this experiment was clearly due to electromagnetic induction.

II. To prove that the effects increased directly with the strength of the primary current used and diminished with the resistance of the secondary current.

(a) Two quarter-mile squares of insulated wire were opposed to one another, and the distances between the front faces varied from eight yards to 192. Current of one and two amperes respectively were sent into one square, and the induced effect in the second square with two amperes was invariably twice that with one ampere. The measurements were made with a reflecting galvanometer.

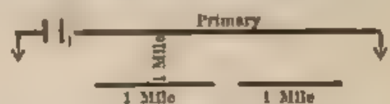

FIG. 7.

(b) Open wires were placed parallel to one another, and a mile apart horizontally, Fig. 7. The primary circuit was two miles long. The other, the secondary current, was divided into two equal one mile lengths. With a primary current of ·22 ampere the vibrations were just audible in a telephone fixed to either of the single-mile lengths of the secondary, the total resistance in the latter circuit being 85 ohms. With a similar current (·22 ampere) in the primary and the secondaries joined into a two-mile length the same limit of audibility was reached when the resistance in the secondary was doubled—that is, it was raised to 170 ohms. Next, the current in the primary was doubled, or increased to ·44 ampere, and with a one-mile secondary the total resistance had to be doubled in order to reach the same limit. Finally, when the current in the primary was raised to ·88 ampere—four times the original figure—then the same limit was reached when the resistance was quadrupled.

III. To find how the effects varied with the length of the inductive system and with the distance separating them.

The law for variation of length and distance is very complicated and depends wholly on the form of the circuit and its various reactions. It may be briefly summarised as follows, but the experiments upon which these conclusions are drawn are given as an appendix, together with the equations developed from them.

Let l = length and d = distance apart of two conductors assumed equal and similar, then

(a) With two infinitely long straight lines it varies inversely as d alone.

(b) With one infinitely long straight wire, and a wire of finite length, it varies as $\frac{l}{d}$.

(c) With one infinitely long straight wire opposed to a rectangle, the law becomes

$$2\,l\left(\frac{1}{d}-\frac{1}{D}\right)\mathrm{M},$$

where D is the distance from the face to the back of the rectangle.

(d) Where the rectangle is replaced by a square, the above formula becomes

$$\frac{2\,l^2}{d\,(l+d)}.$$

(*e*) With a rectilinear wire of finite length opposed to a square, the length of the former being equal to the face of the latter, it varies as

$$\frac{l}{d}.$$

(*f*) With two squares of equal dimensions opposed to one another, Fig. 9, the effect varies, where l is great compared with d, as

$$\frac{l}{\sqrt{d}}$$

but when d exceeds half l, it varies as

$$\frac{l}{d}.$$

Fig. 8.

Note.—With cases *c*, *d*, *e*, and *f*, if d became very great, the effect would diminish and ultimately disappear, owing to the opposing current in the back of the square having practically the same influence as that in the front. When d is very great, the effects due to a and a_1 may be neglected.

(*g*) With two rectilinear wires of equal length, if the effect of the magnetic waves due to the return current through the earth be neglected, then when l is great compared with d it varies as

$$\frac{l}{d},$$

but when d is great compared with l, it varies as

$$\frac{l^2}{d^2}.$$

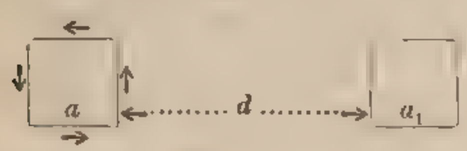

Fig. 9.

The complete formula for the aerial portion of the circuit is as follows:

Let C_1 = current through primary;
q_2 = quantity induced in secondary;
r_2 = resistance of secondary;
l = length of either wire;
d = distance between wires;
then M constant in C.G.S. units,

$$q^2 = \frac{c_1}{r_2} \frac{\sqrt{l^2 + d^2} - d}{d} \times M.$$

The complete formula must, of course, allow for the reverse effect of the return circuit through the earth. I hope later to obtain sufficient data on which to base such a formula.

The value of M, obtained from a series of experiments on two parallel squares of wire 1,200 yards in length and five yards apart, was found to be ·003.

(*h*) The difference in water as compared with air is not very marked. In certain experiments, which were considered reliable, and which appear on Table I., it was about 6 per cent. more in the air than in water. The result was probably due to the magnetic waves being degraded into electrical currents in traversing the conducting sea-water.

IV. Practical Experiments.

The Bristol Channel proved a very convenient locality to test the practicability of communicating across a distance of three and five miles without any intermediate conductors. Two islands, the Flat Holm and the Steep Holm, lie off Penarth and Lavernock Point, near Cardiff, the former having a lighthouse upon it. On the shore two thick copper wires combined in one circuit were suspended on poles for a distance of 1,267 yards, the circuit being completed by the earth. On the sands at low-water mark, 600 yards from this primary circuit and parallel to it, two guttapercha-covered copper wires and one bare copper wire were laid down, their ends being buried in the ground by means of bars driven in the sand.

One of the guttapercha wires was lashed to an iron wire to represent a cable. These wires were periodically covered by the tide, which rises here at spring to 33ft. On the Flat Holm, 3·1 miles away, another guttapercha-covered copper wire was laid for a length of 600 yards.

There was also a small steam launch having on board several lengths of guttapercha-covered wire. One end of such a wire, half a mile long, was attached to a small buoy, which acted as a kind of float to the end, keeping the wire suspended near the surface of the water as it was paid out while the launch slowly steamed ahead against the tide. Such a wire was paid out and picked up in several positions between the primary circuit and the islands.

The apparatus used on shore was a 2-h.p. portable Marshall's engine, working a Pike and Harris's alternator, sending 192 complete alternations per second of any desirable strength up to a maximum of 15 amperes. These alternating currents were broken up into Morse signals by a suitable key. The signals received on the secondary circuits were read on a pair of telephones—the same instruments being used for all the experiments.

The object of the experiments was not only to test the practicability of signalling between the shore and the lighthouse, but to differentiate the effects due to earth conduction from those due to electromagnetic induction, and to determine the effects in water.

I have already alluded to the way in which the lines of current-flow were mapped out. It was possible to trace without any difficulty the region where they ceased to be perceptible as earth currents and where they commenced to be solely due to electromagnetic waves. This was found by allowing the paid-out cables, suspended near the surface of the water, to sink. Near the shore, no difference was perceptible whether the cable was near the surface or lying on the bottom, but a point was reached just over a mile away where all sounds ceased as the cable sank, but were recovered again when the cable came to the surface.

The total absence of sound in the submerged cable rather surprised me, and it leads to the conclusion, either that the electromagnetic waves of energy are dissipated in the sea water, which is a conductor, or else that they are reflected away from the surface of the water like rays of light.

Experiments on the Conway estuary showing the relative transparency of air and water to these electromagnetic waves, tend to support the latter deduction, for if much waste of energy took place in the water, the difference would be more marked. As it is, we have ample evidence that the electromagnetic waves are transmitted to considerable distances through water, though how far remains to be found.

There was no difficulty in communicating between the shore and Flat Holm. Messages were read. Mr. Gavey, who was making the experiment on the island, wrote me: "There was then somewhat a lengthened pause, due to a slight derangement of the machinery on the mainland, but at 2 p.m. I heard clearly and distinctly the following: 'Here Haskayne' (one of his assistants) 'with a message

from Mr. Preece for Mr. Gavey.'" I was in London that day. "Then followed the announcement of the sad and sudden death of Mr Graves, which cast a gloom over the success of the experiment. It seemed an extraordinary fact that the first readable message transmitted for such a distance by such means should announce the death of the head of the Technical Department."

The distance between the two places was 3·1 miles. The attempt to speak between Lavernock and Steep Holm was not so successful. The distance was 5·35 miles, but though signals were perceptible, conversation was impossible. There was distinct evidence of sound, but it was impossible to differentiate the sounds into Morse signals. We were just on the limit of audibility, and we were using our maximum power. If either line had been longer, or the

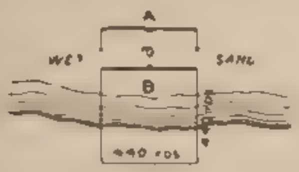

FIG. 10.

primary current stronger, we should have spoken as was done at Flat Holme.

The fact indicated by the formula for parallel wires that the limiting distance increases directly with the square of the length of the circuits, has a very important bearing on the practical results of these experiments, for it shows that if we can make the length of the two lines long enough, it would be easy to communicate across a river or a channel.

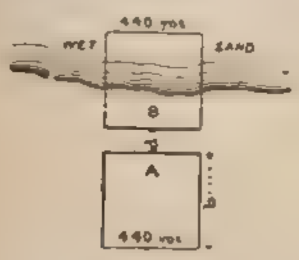

FIG. 11.

Of course, as previously pointed out, the formula does not take into account the effects of the reverse magnetic waves generated by the return current through the earth, and at present no data exist on which a satisfactory calculation can be based; but, for example, there is little doubt that two wires 10 miles long would signal through a distance of 10 miles with ease.

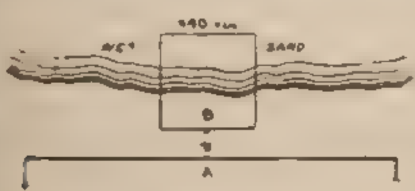

FIG. 12.

Although communication across space has thus been proved to be practical in certain conditions, those conditions do not exist in the cases of isolated lighthouses and lightships, cases which it was specially desired to provide for. The length of the secondary must be considerable, and for good effects, at least equal to the distance separating the two conductors. Moreover, the apparatus to be used on each circuit is cumbrous and costly, and it may be more economical to lay an ordinary submarine cable.

Still, communication is possible even between England and France, across the Channel, and it may happen that between islands where the channels are rough and rugged, the bottom rocky, and the tides fierce, the system may be financially possible. It is, however, in time of war that it may become useful. It is possible to communicate with a beleagured city either from the sea or on the land, or between armies separated by rivers, or even by enemies.

A use to which these electromagnetic disturbances can be applied is to indicate to ships their contiguity to lighthouses and land-falls. Experiments are being made in this direction by Mr Stevenson, of the Northern Lights Commission, on the coast of Scotland, but no results have yet been published. He proposes to submerge a cable on a given fathom line through which special automatic distinguishing signals are being sent, so that a ship approaching or crossing this line can pick up these signals on board and learn her true position.

I have also pointed out that as these waves are transmitted by the ether they are independent of day or night, of fog or snow or rain, and, therefore, if by any means a lighthouse can flash its indicating signals by electromagnetic disturbances through space, ships could find out their position in spite of darkness and of weather. Fog would lose one of its terrors, and electricity become a great life-saving agency.

APPENDIX.

I. EXPERIMENTS TO DETERMINE THE ELECTROMAGNETIC INDUCTION, BOTH IN WATER AND AIR, BETWEEN A RECTANGLE AND A FINITE LINE OF LENGTH EQUAL TO THE FACE OF THE RECTANGLE.

Currents were sent through the rectilinear circuit, A, by means of a suitable key, and the induced effect on the rectangle was observed on a carefully-adjusted reflecting galvanometer.

EXPERIMENT WITH CONDUCTORS COVERED WITH SEA-WATER (see Fig. 10).

d yds	Relative values of d.	Current through A (amps.).	Discharge deflection from B.	Equivalent in micro-coulombs.	Remarks.
100	1	2·00	16	·024	18ft. water over A
200	2	2·00	8	·012	—

Accumulators in Paris.—The shareholders in the Société des Accumulateurs Electrique (Faure-Sellon-Volckmar) have agreed to a dissolution of the company, and have authorised the directors to transfer the assets to the Societe pour le Travail Electrique des Metaux.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence: Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET,

LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months
United Kingdom	3s. 3d.	...	6s. 6d.	...	13s. 0d
Other Places	4s. 11d	...	9s. 9d.	..	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s*

TELEPHONES.

The Postmaster-General at present occupies an anomalous position in respect to the legacy he inherited from the late Government—the Telegraph Act, 1892, on the one hand and the great telephone monopoly on the other. Sir James Ferguson was persuaded by the New Telephone Company to countenance and ultimately guide to completion a scheme devised by that company for the confusion of their opponent, the National. Being new competitors in the field, they saw the danger of isolation in certain urban districts, and appreciated the difficulties and delays attendant upon the creation of a rival system of trunk lines. They therefore convinced the Post Office officials of the expediency of purchasing the National trunks, whether the National liked it or not, and allowing New subscribers to use them on an equal footing with the rest. The New Company had likewise made an interesting arrangement whereby the City of London Electric Light Company had spent some £60,000 of their shareholders' money in laying tubes not required for the electric light, but designed for the use of the New Telephone Company if the necessary permission could be got from the powers that be. The expediency was therefore clear of obtaining an Act to enable electric light companies to lay tubes for telephone purposes. This, too, the late Postmaster agreed to, and the Bill in due time became an Act, notwithstanding the opposition of the National. So far all went well. The National had the worst of the game at all points, and having the sense to know it, their tactics changed. They sailed into the enemy's camp radiant in smiles, admiration, and congratulations, and obligingly offered to subscribe two-thirds of their rival's capital in return for a less than one-half representation on the Board. The bait took, and the rest is known. For any useful purpose the New has disappeared. But the Telegraphs Act remains, and the Postmaster's dilemma is in this wise.

Under the Act he has already spent many thousands of pounds in erecting new trunk lines. Belfast he has connected to Glasgow, and it is understood that a great north and south line from Scotland to London *viâ* Yorkshire and Lancashire is far advanced towards completion. But where are his customers to come from unless he makes an agreement with the National to switch their local subscribers on to the Post Office trunks? The prospective New Company's exchanges have disappeared, and he is left with his own insignificant exchanges at Newcastle, Leicester, and Cardiff, together with those of the National practically everywhere. And granting licenses to corporations will not help much. Suppose Glasgow gets a license and opens an exchange, without an agreement with the National neither the Post Office nor the National trunks would be available to the Glasgow Corporation subscribers, for the Post Office trunks have no exchanges at their other ends, while the National Company would refuse to allow theirs to be used. So the Postmaster sees the necessity of an agreement with the National, while that com-

pany is naturally taking advantage of its strong position to exact terms of which the public would possibly not approve if they came to be published. Consequently neither Mr. Morley nor the National are conceivably anxious for the agreement to be laid before the House until after signature, and Mr. Morley's apparent reluctance to bring the agreement forward has been commented on by several of our contemporaries. Fate has placed in the hands of the National directors a tomahawk originally fashioned for their destruction, and they would be foolish, from their point of view, if they failed to use it. But the position is most unsatisfactory for the telephone users. High rates and bad service will probably still be the rule, and the monopoly more grinding than ever.

ANALYSIS OF BOARD OF TRADE RETURNS.

In the early days of these returns we had some correspondence with the Board of Trade asking if the Department was likely to analyse and tabulate the returns. The Department did not do so, but subsequently a contemporary very pluckily made an analysis. We have been asked again and again to undertake the analysis of all the returns, and in this issue put forward a suggested form of such analysis. We have always held the opinion that too little attention was paid to the percentage of loss. Many companies refuse point-blank to give the figures necessary to show this percentage, and it may be taken without a grain of hesitation that in all cases where such figures are not given they are withheld because their publication would be damaging to the concern. We incline to the opinion that the percentage of loss will tell us far more as to the economy of design in distribution than any other figure or set of figures. Whether it will tell in favour of high pressure or low pressure we do not know, but most emphatically we deny that estimated losses have the same value as ascertained losses. In the production, or rather in the distribution of gas, losses are acknowledged, and every effort is made to reduce such losses. In electrical work it is possible to estimate the necessary loss, and the nearer the producer approaches to the theoretic figures the nearer his distribution comes towards perfection. Some companies give details as to losses in batteries and in mains with the losses unaccounted for, and it is really the smallness of such unaccounted for losses that in a measure determines the excellence of distribution, especially when the systems adopted are similar. The check upon our analysis is that the sum of the items should approximately equal the cost per unit, as obtained by taking the total cost as shown by the revenue account and dividing that amount by the number of units sold. If this test, which we venture to think is the correct one, is applied to the analyses hitherto published, it will be found that discrepancies exist. These may be accounted for in various ways. For example, rightly or wrongly, we place depreciation among the cost items, and do not consider that it can justly be otherwise placed. Railways do not depreciate, but keep their concerns efficient at the cost of revenue. Thus wear and tear is annually replaced and efficiency secured. In electrical matters wear and tear is not annually replaced, except by depreciation, which is merely another way of doing it. Insurance, again, approaches both the character of rent or tax as well as of depreciation. We put it along with rent and tax. It is by differently distributing such items that discrepancies may be found in the distributed items, but, unfortunately, differences will be found in the totals, and this is the main reason for our action. The error of a tenth of a penny may not seem much, but when the error has to be multiplied by hundreds of thousands the total sum is considerable. In fact, the tenth of a penny or even less will make all the difference between a large profit or a large loss. While, therefore, we make no claim to infallibility in the manipulation of figures, we do claim that it is important to know the actual cost per unit sold, and this is easily obtained when the total cost and the number of units sold is known. The amounts of the various items that make up this total are also worthy of great consideration. The variations in these show where waste and economy prevail, also where the apparatus and machinery are superior in design, make, or usage. What is the reason that the coal bill in one station is a farthing or a halfpenny per unit more or less than at another station within the same or a similar district, except that the boilers and engines at the one are more or less economical than at the other. It is not our intention at the present to draw inferences; we are seeking advice as to what information to give and how to give it.

ARMATURE PROPORTIONS.

BY F. M. WEYMOUTH.

A question on dynamo design that may often occur, especially to a beginner, has reference to the best proportions of length to diameter in an armature. It is hence the object of the following remarks to bring forward some of the considerations that bear on this subject. Assistance may thus, we would hope, be afforded to such as to whom this question may have had something of the nature of an unsolved problem.

Among the items demanding attention, the price of copper is of importance. If this metal is low in the market, it will pay to put a greater amount of it into a machine than when the price is high. Moreover, it is questionable whether much true economy would be attained by buying up a quantity of given sections of copper to lay in stock, even should the opportunity offer of obtaining it at a low figure. Copper at the best is expensive, and a large quantity might thus be laid in which for a time would be of no use, thus representing capital without interest. Hence it is usually bought as it is wanted, and ruling prices have to be watched.

To consider first, then, the application of these remarks relating to copper, we find the point to be aimed at is the attainment of a maximum amount of magnetic induction in the magnets, and of E.M.F. in the armature coils, with a minimum of copper. As is well known, the smallest periphery that can enclose any given area is a circle. Hence the copper is used most economically when the coils are circular. This is exemplified in the Thomson-Houston machine, wherein the armature is spherical and the magnets cylindrical, though as to the former, this only holds good in respect of the exterior coils, as the inner coils, owing to the overlay at the ends, become less circular.

common, however, among other makers, to have cylindrical magnet cores. Nevertheless, perhaps the majority adopt magnets of rectangular cross-section. The armatures are likewise rectangular on their longitudinal, which is also their effective, section. Now, the rectangular area having the shortest periphery is the square. The more oblong any given area is, the greater will be its periphery. Thus, an area of, say, nine square inches may be enclosed in a square of 3in. × 3in. having a periphery of 3in. × 4 = 12in. If this area be shaped 6in. × 1½in., its sides becoming thus as 4 to 1, its periphery will be 15in., or 25 per cent. more than when square. This would thus point to the advisability of adopting a short, broad machine, with magnets of square cross-section, or nearly so, and an armature having a core one diameter in length; and with this, of further obtaining the option of making the magnet cores cylindrical and the coils circular, and so to dispose the copper still more economically.

But a point, on the other hand, immediately rises here which destroys the harmony with which this question is apparently settled. It has only to be mentioned to be at once recognised that, with regard to the armature, it is the parallel inductors alone on the circumference that generate

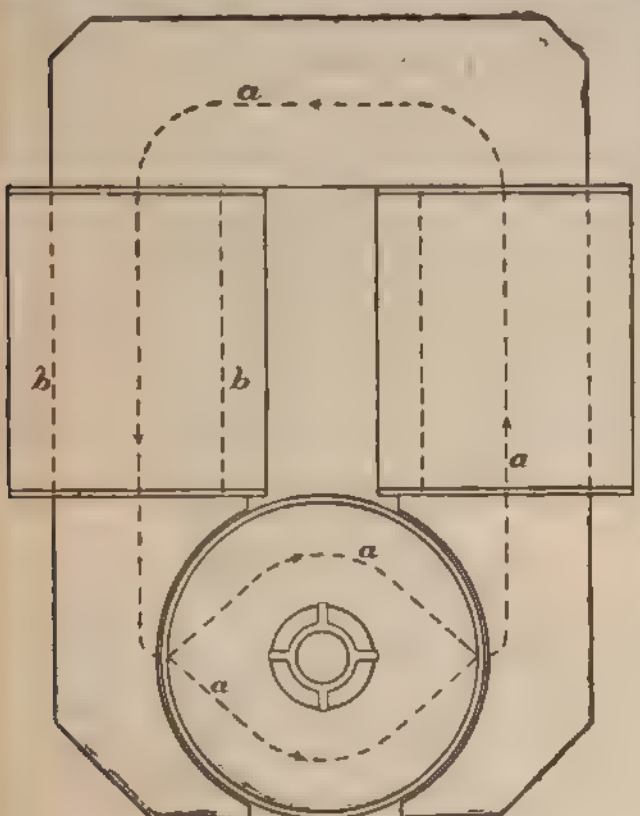

FIG. 1.

current, while the copper connections across the ends have no value in this respect. Hence, it will be seen that to apply the copper most effectively, and so economically, in this case the armature length should be much greater than the diameter, and thus as large as possible a proportion of the copper be employed cutting lines of force and generating E.M.F. It will therefore be seen that so far from the question being one of an easy harmonious settlement, we are at the outset confronted with conflicting requirements, the former needing that the armature should be of square longitudinal section, and the latter that its length should be as great as possible in proportion to its diameter. But of this we shall find more.

Now, as comparisons are often made clearer by supposing an extreme case in one direction or the other, we may adopt that method here. Thus, we may compare the case of a machine having an armature core one diameter in length, with the case of one having the armature core of the same effective longitudinal sectional area, but four diameters in length. These we illustrate in Figs. 1 and 2 herewith. In the former the armature core is, say, 24in. in both length and diameter, while in the latter it is 12in. diameter and 48in. long. The central hole in the short armature is, moreover, twice the bore of that in the long one, so that the same proportion of the diameter is removed in each case, and the actual total effective longitudinal sectional area of the core proper is the same in both, though of different outline. The circumference of the short core will be about 75in., and of the long core about 37·5in. We may use this comparison looking at the subject from all points; and we, moreover, suppose the same output from each—at least, to be intended. It will now at once be obvious that a much larger number of turns can be put on the circumference of the short armature than on the long one, unless on the latter they be laid in two layers. This arrangement, however, would cause the air-gap, or distance between the inner surfaces of the pole-pieces and the core, to be nearly (the clearance not being doubled) twice as great in the case of the long core as the short one. As these air-gaps are the most formidable source of reluctance to the whole magnetic circuit, doubling them would make a serious difference, and our comparison hence would not perhaps be reasonable. The difficulty may, however, be obviated by giving the long armature twice the speed of the other, and so do with only half the number of turns in its winding. This will thus render only one layer of conductors necessary on its circumference; while its increased speed would but be agreeable with the natural law that the limits of speed are greater in the case of small than of large diameters. The peripheral velocity also will now be the same in both.

Having thus assumed comparative cases, we may consider the copper, and our remarks here will apply more especially to drum armatures. Let us suppose that on each

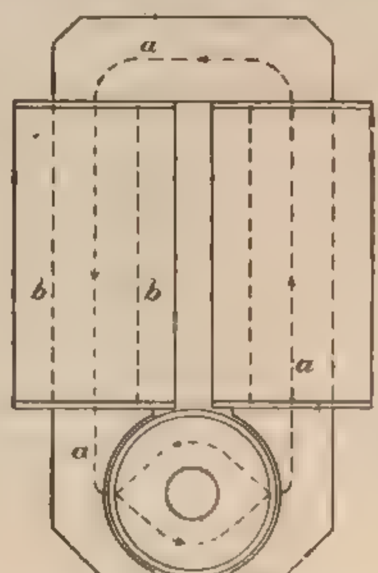

FIG. 2.

armature the layer of copper conductors is ½in. thick, while the insulation, being of the same proportion in both, may be disregarded. Now, with the short core, rather more than half the copper, through its not running for constructional reasons in direct lines across the ends, is idle. With the long armature, for the same reasons, we may say that rather more than a quarter of the copper used at the ends, is also idle. We may now look at the totals of copper. In the case of the short core, the circumferential surface is 75in. × 24in. = 1,800 square inches. With ½in. layer of conductors we get 1,800 × ·5 = 900 cubic inches of copper. To this add rather more than as much again for the end connections, as above explained, and we get, say, 1,000 + 900 = 1,900 cubic inches total of copper for the short armature. With the long armature, the circumferential surface being 48 × 37·5 = 1,800 square inches, or the same as the other, we have also 900 cubic inches for the parallel conductors. But here we need add, as stated, rather more than a quarter only for the end connections. We thus get, say, 300 + 900 = 1,200 cubic inches total of copper on the long armature—that is, 700 less than on the short armature. In other words, the square armature has

rather over 58 per cent. more copper than the long armature for the same output.

The field coils have now to be considered. In the case of the short machine, as shown in Fig. 1, the section at *b b* is 24in. × 13in. With the long machine this is 48in. × 6½in. The periphery of the former is thus 74in., and of the later 109in. But allowing for, say, 2½in. thickness of copper, the mean periphery of the coils will be 84in. and 119in. respectively. There will thus be 35in. (in mean peripheral length) more copper in one coil of the long machine than in one coil of the short machine; or, in other words, the coils of the former will contain about 41½ per cent. more copper than those of the latter. The mean periphery of one corresponding coil on a cylindrical magnet would be 75in., or 44in. less than with the long machine, which gives about 58½ per cent. more copper in the coils of the long machine. There will thus be either about 41½ or 58½ per cent. more copper in the magnet coils of the long machine than the short one, according as to whether the limbs of the latter are rectangular or circular in section. Hence, whereas in the field coils of the short machine we find a saving of 41½ or 58½ per cent. as compared with those of the long machine, yet in the armature of the short machine we have found a loss of about 58 per cent. in copper as compared with the armature of the long machine.

But our ½in. thickness for the armature coils is empirical; and so also is the 2½in. for the magnet coils, and the latter may be any thickness up to 3in. or more. It may thus now be observed that the absolute value of the 41½ or 58½ per cent. saving in the field coils of the one (both limbs being considered) may greatly exceed the absolute value of the 58 per cent. saving in the armature of the other machine. The proportional monetary value of the magnet coil percentages would be still further increased if they were shunt wound, owing to the much greater cost of fine insulated wire as compared with thick coils. Hence, to arrive at the greatest economy a compromise must be effected, and the machine so designed as a whole that the absolute value of the loss in the one direction should be on a par with the gain in the other. It thus follows that with any given depth and thickness of field coils, as the absolute value of the percentage gained by the long armature must vary with the thickness of its winding, a greater length of armature will be justified when heavily wound than when only lightly wound for small currents. In the latter case, indeed, it becomes very plain, especially in a machine with shunt-wound magnets, economy in copper is to be found in the direction of a short armature and cylindrical magnet cores.

Now it will be noted that in our remarks so far we have spoken of the same *intended* output from each machine only. We have assumed field coils of the same magnetomotive force in each machine. With the armatures as described in connection with Figs. 1 and 2, it might at least seem that the output would be the same in both cases. But some points yet remain for consideration, however, that will affect this conclusion. We allude to the comparative length, of magnetic circuit which we mentioned near the commencement of our remarks. It will be observed in Figs. 1 and 2 how that the mean path of the magnetic circuit in each machine is represented by a dotted line, *a a*, divided in two through the armature. Now, in Fig. 1, this measures in total length round about 140in., while in Fig. 2 it is about 95in., making a difference of nearly 50 per cent. In both cases the air-gap is the same. Now, perhaps, about four-fifths of the magnet coils may be employed solely in overcoming the resistance offered by the air-gaps to the magneto-motive force they exercise. Hence one-fifth only is concerned with forcing lines of magnetic induction through the iron of the circuit. Now, the reluctance of the iron varies as its length, and inversely as its cross-sectional area. The cross-sectional areas being the same in the cases we are supposing, length alone need be considered; and it follows that the reluctance in the iron circuit in the short machine, Fig. 1, is nearly 50 per cent. more than in the long machine, Fig. 2. Hence there will need to be added, on this count, to the magnet coils of the short machine 50 per cent. of one-fifth of the ampere-turns, as compared with those on the long machine, or one-tenth more, to get the same strength of field. With cylindrical magnets, of which the cores would be 20in. in diameter to be of the same cross-sectional area, the machine would become still broader, and the magnetic circuit becoming yet ·ger, a greater proportion than one-tenth would need to be added to overcome the extra reluctance of the iron circuit.

On the other hand, the leakage and waste field in the long machine must be considerably more than in the short one. Leakage, it may doubtless be said, can only take place as there is opportunity. Now this, as is well known, is especially afforded by the close proximity of a pole of opposite polarity, and by an extended protruding polar periphery. This opportunity, as here described, is precisely what is offered much more in the long machine than the short one; for on the latter point it will be remembered that lines of magnetic induction have a tendency to crowd about and out of a projecting point or edge, especially if protruding in their natural path, a greater facility of exudation being thereby afforded. In other words, it is much easier for the lines, though compressed into greater density, to flow out through a ridge (more or less) projecting in their course than from a flat surface that recedes.

In our long machine, Fig. 2, it may be observed, first, that the pole-pieces are much nearer each other than in the short machine; and, secondly, that the horns of the former, in length parallel with the shaft, are twice as long as those of the latter. The sectional areas in plan of the pole-pieces are very narrow; but these areas are the same in total amount as the corresponding sectional areas in the short machine. Being thus altogether nearer, and also more extended in direction parallel with the shaft in the case of the long machine than in the short machine, it is obvious that of the total amount of magnetic induction resulting from the magnet coils, more will be wasted, or pass as free magnetism through the air from one pole-piece to the other, in the former than in the latter. Mathematical treatment of this subject may be found in Prof. Silvanus P. Thompson's "Dynamo-Electric Machinery."

Our purpose, however, is sufficiently served in the fact of the greater waste field with the long machine being established; for now it will be seen, that to make good this loss, additional ampere-turns must be put on the magnet coils of the long machine. Hence, whereas we have but just discovered that some of these turns might be *reduced* on the long machine, because of its shorter magnetic circuit, we now find that, more or less, they will need to be put back again to cover the leakage. This forms, in fact, another case of conflicting requirements.

A remaining point that may be noted concerns the core. Calculation will show that the short core, although of the same longitudinal sectional area, will yet have twice the weight of the long core. Hence it may be taken, roughly, that the short core will cost twice as much as the long core, which forms another item for consideration.

We thus find, in conclusion, that inasmuch as the two questions of the length of magnetic circuit and the waste field have a neutralising or cancelling effect on each other, attention may be reverted to the cost of the copper that may be used, and also of the iron discs. It would therefore appear that armatures of great length are most justified when wound for heavy currents. The great total amount of copper such as there would then be in their winding would render the saving due to the increased length and shortened diameter of greater proportional account, to which may be added the further saving (above alluded to) effected by the lesser total weight of charcoal iron core discs. While, especially if the machine were series wound, thus avoiding the expense of fine shunt winding, economy with the copper of the magnet coils becomes proportionally of less consequence, and a long rectangular section of magnet will not perhaps be so inadvisable.

Aix-la-Chapelle.—The Municipality has just granted permission to the Aix-la-Chapelle and Burtscheid Tramway Company to substitute electric traction for the horse cars now in service. The current will be provided by the local electricity works, and the system to be introduced is the overhead trolley method.

PATIN FLYWHEEL ALTERNATOR.

Direct-driven alternators have been familiar to electrical engineers in the Westinghouse and other plants, though apparently until lately a preference has been shown in English practice for rope-driven alternators. We illustrate this week a direct-driven alternator of French construction of the Ferranti type—the Patin "flywheel alternator," connected direct with a horizontal engine of the Blondel type with Corliss valves, made by E. Boyer. The Corliss detents are placed two and two beneath the cylinder at each end, and give rapid opening and shutting at all positions of the piston from 0 admission up to maximum admission of 75 per cent. In the variable detent of the Blondel, a single excentric would only vary the admission from 0 to 35 *per cent.,* but with two excentrics the admissions can be varied to 75 per cent.; further, for ordinary admissions around 20 per cent. the closing of the parts is extremely rapid—[illegible]th to $\frac{1}{30}$th of a second—as the excentric radius is then vertical and the greatest speed is at that point.

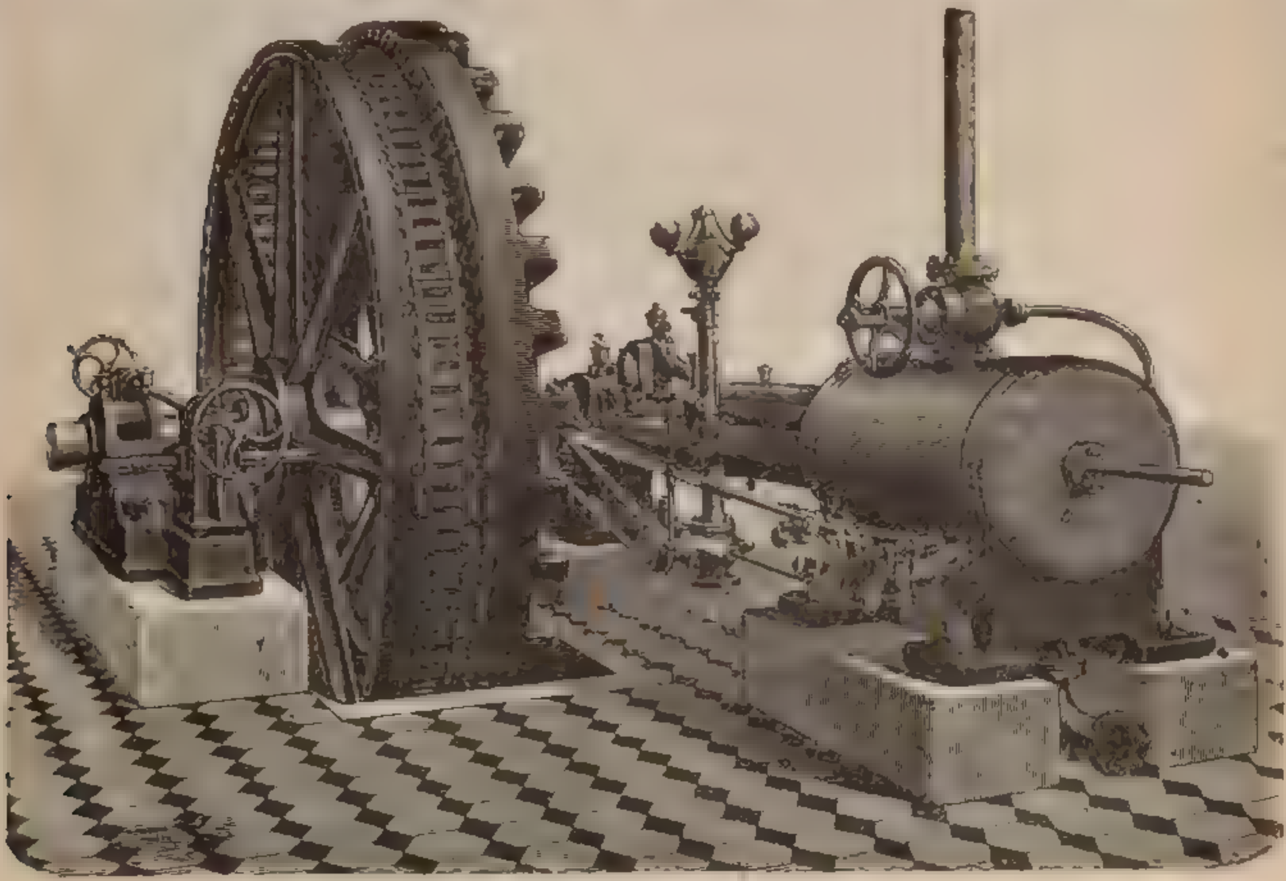

Fig. 1.—Patin Flywheel Alternator.

The most interesting part of the engine is the flywheel, which constitutes, in effect, the field magnets of the alternator on the system of M. O. Patin, which has been perfected by long experience.

Alternating machines, if direct driven, usually require a relatively high speed, which means a higher steam consumption, or else necessitate the use of gearing if slow-speed engines of greater efficiency are employed. The flywheel alternator alone avoids both disadvantages. As the field magnet forms also the rim of the flywheel, foundations for the dynamo are avoided, the oiling expenses are reduced, space is saved, and the superintendence is rendered easier.

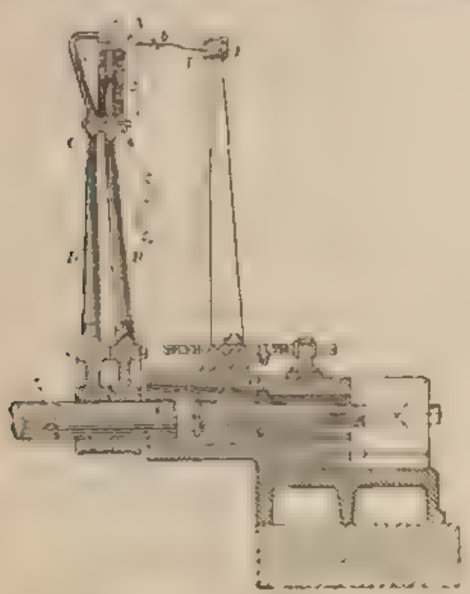

Fig. 2.—Patin Flywheel Alternator—Details.

Fig. 3.—Induction Poles.

In the illustration the armature is shown slightly drawn back from the fields in order to distinguish the two parts

of the alternator. The armature, being fixed, is not acted upon by any mechanical force other than the magnetism of the fields, and is not liable to deterioration. High tension collectors are also avoided, and there are no brushes, the mains being, of course, connected direct to the terminals.

For large installations the cost of generating energy is most important, and engines of slow speed and high efficiency are desirable. M. Patin therefore uses for his alternators speeds of 60 to 100 revolutions per minute.

The alternator comprises thus:

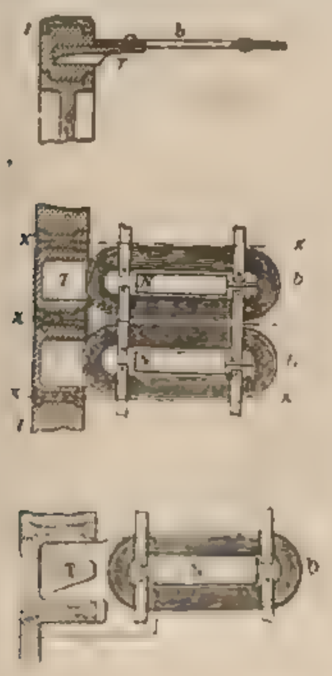
(1) The flywheel field magnets, fastened to the crankshaft of the engine, serving the double purpose of engine flywheel and dynamo fields.

(2) A fixed armature, which, however, can be displaced along the axle in a supporting socket so as to separate it from the fields for inspection of the coils.

(3) A supporting socket of the armature, fixed upon the foundation of the outside bearing of the crankshaft, and forming part of the same bearing.

(4) Various accessories: such as shifting screw of armature, collecting rings for exciting current, etc.

(5) An exciting dynamo.



FIGS. 4, 5, and 6.—Details of Armature Coils.

Flywheel Fields.—The field magnets comprise two distinct parts: first, an inside crown, A (Fig. 2), in one or two pieces of cast iron, connected to the hub by arms, B, and carrying on its periphery soft iron poles, P (Fig. 3), forming the internal part of the magnetic field. Each of the poles, P, carries an extension, E, fixed by bolt and screw, which can be taken off to allow the field-magnet coil, *y*, to be placed around the core. The number of the poles, P, is variable for each size of dynamo and according to the speed of rotation, so as to obtain a constant periodicity for all machines; and, second, a crown of cast iron, A, carrying on its external face projections forming the external poles, P^1, equal in number to the internal poles, P. The exterior crown is connected solidly to the interior crown by a cast-iron ring and radial arms, C, solidly bolted to the internal crown, A. The ring, C, is connected by arms, B^1, to a hub bolted to that of the internal crown. The assembling of these parts is arranged so as to leave between the poles, P and P^1, a regular and sufficient space for the coils of the armature.

Armature.—The armature is composed of a cast-iron crown, I, Figs. 2-7, with equidistant cavities; arms connect it with the bored hub, M, rubbing with slight friction on a socket, D, which act as support and guide. In each of the cavities of the armature crown is sealed the end of a bronze plate, serving as core to the coil. The sealing is done with a material which completely insulates it from the crown. Each armature coil, *b*, is independent of the others, and is easily replaced: it consists of a core, N, of bronze, laminated to avoid eddy currents; on this core are wound a strip of copper and a strip of insulating fibre placed together. The coil thus formed is carefully varnished to a circular surface with gum-lac. Each bronze carrier carries two coils, bolted thereto.

The set of carriers, after sealing, is turned up in the lathe, the cores of the coils being centred and exactly fitted to measure, presenting a perfectly centred cylinder between the field-pole extensions, with a play of a few milimetres. The projecting parts of the coils are kept rigid by metallic hoops insulated from the coils.

On the upper part of the armature are fixed two terminals for taking off the current.

FIG. 7.—Armature.

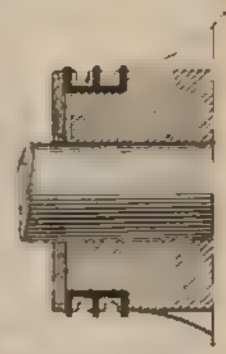


FIG. 8.—Collector Rings.

Supporting Socket.—The armature is fastened on a strong supporting socket of cast iron, D (Fig. 2), through the centre of which passes the engine crankshaft; it forms one with the base plate of the outer bearing, bolted solidly to the foundation. Longitudinal movement is prevented during working by a linch-pin arrangement.

Withdrawal Gear.—To inspect or replace coils, the armature is withdrawn from the fields by a simple arrangement of threaded rod, M, with two collars, turning freely in a bearing fixed to the supporting socket, Fig. 2, working in a screwed slot in the hub of the armature. A ratche lever serves to work it; and the hub of the armature slide to and fro as desired along the supporting socket. The length of the fixed wedge of the supporting socket is limited, so as to allow the armature to turn at will on a socket when withdrawn from the field magnets.

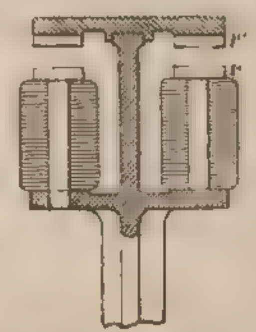

FIG. 9.—Alternator with Double Field Magnets.

Exciter Rings.—The exciting current, from a separate exciter or commutated coils, as the case may be, is led into the fields by two bronze rings fixed on the flywheel hub, insulated by fibre discs, Fig. 8.

The above comprise the various parts of the Patin flywheel alternator, as constructed from 50 h.p. to 300 h.p.; above this the flywheel alternator carries a double magnetic field, Fig. 9, with two armatures on each side.

These alternators, adds the *Revue Industrielle* (from which we take the description and illustrations), are easily put together and attended to; their working is absolutely regular, whatever the variation of load, as the armature does not contain a particle of iron. For powers less than 50 h.p. the alternators run at speeds allowing direct coupling to turbines or high-speed engines.

(To be continued.)

WORLD'S FAIR ELECTRICAL PLANT.*

BY R. H. PIERCE.

Of all the cities that have ever been built, there has never been one in which electricity has played such an important *rôle* as in the White City. The present exposition is the first international exposition in which electricity has been recognised as one of the great departments, and no previous electrical exhibition has equalled the electrical exhibit of the World's Columbian Exposition. Volumes have already been written upon the various electrical exhibits, and all that will be attempted in this brief paper is a description of the great plant which furnishes the electrical service of the exposition. The electrical plant comprises a local telephone exchange, complete systems of police signal and fire-alarm service, and the plant for furnishing electric power and light.

Telephones.—The telephone exchange is a regular exchange of the Bell system. It comprises at present 130 telephones. It supplies service for the offices of the officials, the engineers, and superintendents. It forms an adjunct to the fire-alarm service, and connects the head quarters of the police department, the department of admissions, and of the secret service with all gates and with all portions of the grounds. It contains no points of novelty, but is an interesting exhibit of a great private exchange. It is installed with complete metallic circuits of double and twisted rubber-covered conductors. The circuits comprise 150 miles of No. 18 B. & S. wire, and the service is practically unaffected by the proximity of the immense number of circuits carrying currents, both direct and alternating, and all degrees of current strength.

Police and Fire Signals.—The police signal and fire-alarm systems comprise 137 fire-alarm boxes of the Gamewell Fire Alarm Telegraph Company, and 137 police boxes, and 50 watchmen's patrol boxes of the Police Telephone and Signal Company. These systems are two well known to need even comment, and make the service uniform with that of the city of Chicago, to which it is connected. The boxes are distributed about the grounds and buildings in pairs, each fire-alarm box having a corresponding police box. The number of boxes is estimated to be sufficient for protecting a city of 150,000 inhabitants, and its installation consumed 80 miles of No. 14 B & S rubber-covered wires. The watchmen's patrol boxes are located under the floors of the main buildings, and enable the guard to send in an alarm direct to headquarters without even the loss of time required to reach the nearest fire or patrol box.

Light and Power Plant.—The portion of the plant which especially commends itself to the interest of both the engineer and the architect is the plant for electric lighting and electrical transmission of power. All the electrical machinery for furnishing light and power is located in Machinery Hall, so that the power plant in Machinery Hall is a great central station. I say "central station," but, in fact, the plant is divided, as far as operation is concerned, into nine distinct central stations, each of which, under normal working conditions, is entirely independent. The plant comprises 98 direct-current series arc dynamos, having a total capacity of 5,230 lamps of 2,000 nominal candle power each; 14 alternating-current incandescent dynamos, having a total capacity of 128,000 lamps of 16 c.p.; one direct-current incandescent dynamo, having a total capacity of 800 kilowatts, and 20 direct-current power generators, having a combined capacity of 2,936 kilowatts, or 3,935 e.h.p. In addition to these there, are also four direct current generators having a total capacity of 600 kilowatts, or 804 e.h.p., which serve the double purpose of supplying current to operate the electric fountains and to charge the storage batteries for the electric launches. There are also one direct-current generator of 700 kilowatts, or 938 e.h.p., which operates both arc and incandescent lamps; and, finally, one direct-current generator of 180 kilowatts, and one of 45 kilowatts, a total of 225 kilowatts, or 300 e.h p., which supply the current for search-lights. The entire plant has a generating capacity of 14,916 kilowatts, or 19,989 e.h.p., so that it would require not less than 25,000 i.h.p. to operate all the dynamos to their full working load.

Circuits.—The circuits from all dynamos are carried under the floors of the power plant to the several switchboards, and thence under the floor to the gallery, which runs the entire length of the power plant, and under the aisle directly north of the plant. This gallery is for the greater part of its length 13ft. wide and 9ft. high, and is shut off from the rest of the basement on both sides by walls of expanded metal and cement. Along each side of the gallery is a row, and down through the centre are two rows of cast-iron uprights placed 30ft. apart. These uprights have sockets into which are driven oak cross-arms. These arms carry from four to six pins, and have, in all, sufficient pins and insulators for 280 wires, allowing but one wire to an insulator, but, by the use of a special two-wire insulator designed for this purpose, the capacity of the gallery is greatly increased. From this gallery, the circuits are carried out of Machinery Hall in the main subway and the duct trunk line. All the circuits feeding the east portion of the park are carried in an underground tunnel called the main subway.

Subway.—The main subway, as it passes under the east end of Machinery Hall going north, is a double tunnel, each half of which is constructed as follows: A series of frames are built of 3in. by 8in. timber, and are covered on the outsides, on the top and sides, with 2in. plank. On the inside the top and sides are covered with expanded metal and plaster, and the floor is formed of Portland cement. This forms a practically fireproof tunnel, 6ft. 6in. wide and 6ft. 5in. high. To the timbers on both sides of each tunnel are legged cast-iron uprights 30ft. apart. These uprights carry on each side of the subway 12 five-pin cross arms 2ft. 3in. long, so that one can walk in a 2ft. passage having on either side a regular underground pole line. Conductors are carried on double petticoat insulators, there being capacity in the entire subway for 250 insulators. Here, as in the gallery, many two-wire insulators are used. The subway is lighted by incandescent lamps and drained by hand pumps located at low points. When single insulators are used, all wires are rigidly separated and not less than 5in of air space is allowed. The main subway runs due north to Electricity Building, where the west half enters the building, and then branches, running to the Mines Building, and the east half makes a right-angled turn, running east to the bridge over the north canal. The circuits are then carried under the bridge, and on the east of the bridge the subway is continued to the south-west corner of Manufactures Building, whence, decreased in section, it runs north the entire length of the Manufactures Building, under the West Loggia. It then runs east to a point north of the centre of the Manufactures Building, thence north to the Government Building. Under the Government Building it is constructed with a covering of expanded metal and plaster, both inside and out, and from the Government Building it is continued to the Fisheries Building, where it ends.

Duct Trunk Lines.—The circuits feeding the west half of the park and Midway Plaisance, with the exception of the power circuits, are carried from the gallery under Machinery Hall to the north side of Machinery Hall in a conduit of 3in. and 4in. vitrified tile ducts. Thence the duct trunk line is continued by 30 ducts of pump log of 2½in. bore. Large manhole boxes, 30in. by 36in. are set every 150ft. This trunk line runs under the terminal tracks to the south-west corner of Transportation Annex, whence it runs parallel to the fence, to a point near the north end of the California State Building. From the main subway and duct trunk line, the circuits are distributed throughout the grounds in wooden ducts of 2½in. bore. These ducts form a network all over the park, and are intersected at angles and convenient points by manholes with cast-iron covers. There are in all about 100 miles of these ducts, and about 3,500 manholes. Thus all circuits are carried underground except those south of Machinery Hall and along fences. These are carried on poles, while the power and telephone circuits on the west side of the park are run under the structure of the elevated intramural railway.

(To be continued.)

THE PRACTICAL MEASUREMENT OF ALTERNATING ELECTRIC CURRENTS.*

BY PROF. J. A. FLEMING, M.A., D.SC., F.R.S.

LECTURE III.

THE MEASUREMENT OF ALTERNATING CURRENT POWER.

Having dealt in the preceding lectures with the subject of the measurement of alternating current strength and alternating current pressure, I propose to consider now the measurement of alternating current power.

When the current is flowing through a conductor it dissipates energy, and the rate at which this energy is dissipated is spoken of as the power taken up in that circuit. When a constant current is flowing through a conductor, if we measure the current in amperes and the difference of potential in volts, then the product of these two numbers gives us the power taken up in the circuit measured in watts. In this case two simple measurements gives the required rate of dissipation of energy in the conductor. If, however, we have to deal with an alternating current, in which the current strength is varying from instant to instant, according to a periodic law, and if likewise, the difference of potential between the ends of the circuit is varying in the same periodic manner, we cannot always obtain the measurement of the mean power taken up in the circuit, generally speaking, by taking the product of the √mean square amperes and √mean square volts. What we really require in this case is the mean value of the power taken up in the circuit. We can obtain the measurement of the mean power if we can measure at every instant the true value of the current strength and the difference of potential, supposing these instantaneous values of the current and pressure known at equidistant intervals taken throughout one complete

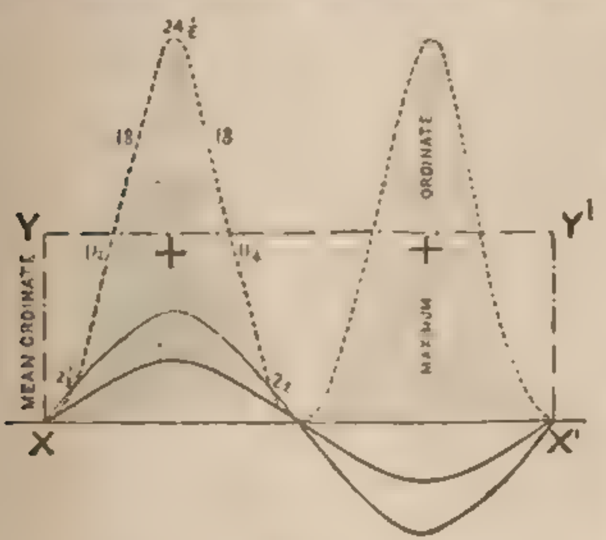

FIG. 1.

period: if we then multiply the instantaneous value of the current by the corresponding value of the pressure, or difference of potential, and multiply these together, we obtain a number representing the instantaneous value of the power, and if we imagine the period divided into a large number of equidistant intervals of time, and those products taken at every such instant, then the mean value of those products, taken throughout the period, would give us a close approximation to the mean value of the power being absorbed by that circuit.

We have seen in a previous lecture how it is possible to determine and describe curves representing the instantaneous values of the current and E.M.F. in the case of an alternating current circuit, but this in general is not a simple matter to do, and we have therefore to resort to other methods of obtaining the required result.

In dealing with the power taken up in alternating current circuits, there are two cases to be considered.

The first case is that in which the circuit is non-inductive. In that case, as before explained, the impedance of the circuit is the same as its resistance, numerically speaking. For such circuits the alternating current flowing in the circuit is in step as regard phase with the alternating potential difference between its extremities. When this is the case the power taken up in that circuit can very easily be measured. If we measure the √mean square value of the alternating current by means of any of the balances of dynamometers described in the first lecture, and if by means of any of the electrostatic or thermal voltmeters we measure the √mean square difference of potential between the ends of the circuit, and multiply these two mean square values together, we obtain the mean value of the power taken up in the circuit, and we arrive at the same result as if we had been able to measure separately the instantaneous values of the current and potential difference at numerous equidistant intervals throughout the phase, and taken the mean value of their products.

* Cantor lectures, delivered before the Society of Arts.

As an instance of this, it may be pointed out that an incandescent lamp may be treated as a practical non-inductive circuit. If this incandescent lamp is traversed by an alternating current, and we measure the current flowing through the lamp by means of, say, a Siemens dynamometer, the potential difference between the terminals of the lamp by means of, say, a Cardew voltmeter, and if we multiply the two scale readings of these instruments together, we obtain the mean value of the power measured in watts taken up in the lamp.

So far, then, all is quite simple, and in dealing with any circuit which we know or can prove to be practically non-inductive, we have no difficulty, by means of two instruments of the proper kind, in determining the real mean power taken up in the circuit. Our difficulties come in when we have to deal with circuits such as transformers, which, when not fully loaded, we know to be inductive. If in this case, we can determine the instantaneous values of the current and difference of potential between the ends of the circuit, then proceeding as above described, we can determine the mean value of the power taken up in the circuit. If, however, it is not convenient to do this we cannot proceed to measure the √mean square value of the current and E.M.F., and then multiply them together. Such a proceeding would lead to a considerable over-estimate of the real power taken up in the circuit. Without going into elaborate proof of this it may be simply sufficient to present the following figures:

In Fig. 1 are shown two simple harmonic curves in step with one another. The semi-period is divided into eight equidistant parts, and ordinates are erected at each point. The values of these ordinates for the two curves, which may be taken to represent periodic current and electromotive curves, are given below the diagram. By squaring each of the values of the ordinates, and taking the square root of the mean of the squares, we obtain for each curve a number which would represent the instrumental value obtained by an alternating current dynamometer or voltmeter. If we multiply together the simultaneous values of current and E.M.F., we obtain a number which represents the instantaneous

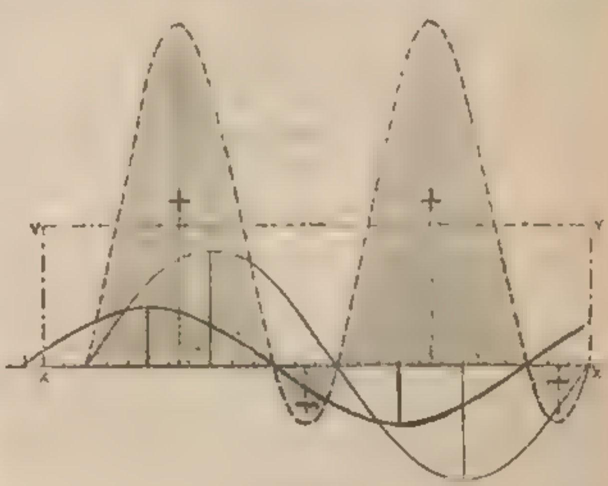

FIG. 2.

value of the power taken up in the circuit, and if we take the mean value of all these separate instantaneous values of the power, we obtain the same number as we do if we take the products of the square roots of the mean of the squares of the instantaneous values of the current and E.M.F. Hence we see that when the two simple harmonic curves are in step with one another, the product of the square root of the mean of the squares of the separate ordinates is equal to the mean value of the products of the corresponding ordinates.

In Fig. 2 are shown two periodic curves, which may be taken to represent a current and an E.M.F. curve, but one of which is displaced backwards relatively to the other. This is what happens in an inductive circuit where the periodic current always lags in phase behind the periodic E.M.F.

If we perform the same operations on the ordinates of these curves, we find that a product of the mean square values is in excess of the mean of the products. In other words, if in such circuit we measure the current by means of a dynamometer, and the potential difference between the ends by means of an alternating current voltmeter, the product of these two numbers gives us a number which is in excess of the true value of the mean power taken up in the circuit.

It is convenient to call the product of the √mean square amperes and the √mean square volts the apparent watts taken up by the circuit, and to call the true mean value of the power the true watts taken up by the circuit.

The ratio between the true watts and the apparent watts is called the power factor of the circuit. Thus, for instance, in the case of a transformer on open circuit, the transformer being of the closed magnetic circuit type, the power factor is about .7, in other words, the real power is only three quarters of the apparent power. In the case of a transformer of the open magnetic circuit type, the power factor may be as small as .1. Hence, you see that an enormous error in this case would be committed by taking the product of the instrumental readings as simply representing true mean power taken up in the circuit. We have, to

consider in what way this true mean power can be practically measured in the case of alternating-current circuits.

There are many methods by which this may be done. A large number of methods have been described which look very excellent on paper, but which do not in practice turn out so well. As I desire only to bring under your notice those methods which are capable of being practically employed, I shall pass over the theoretical methods, and turn at once to the description of those instruments which will enable us to measure practically the power taken up in the inductive circuits. The most practical, and by far the best, instrument to use for this purpose is the electro-dynamometer instrument. Consider a dynamometer, such as one of the Siemens dynamometer described to you in my first lecture. Let the fixed coil of this dynamometer be placed in series with the circuit in which we desire to measure the power being taken up. Let the movable circuit of the dynamometer consist only of a few turns of wire, and let this movable circuit have joined in series with it a non-inductive resistance, which may be formed either of coils or wire, or incandescent lamps. Let this movable circuit with its added resistance be placed as a shunt across the ends of the circuit in which it is required to measure the power, being joined up as shown in Fig. 3. Then when the alternating E.M.F. is applied to the circuit, the fixed coil of the dynamometer (now called a wattmeter) will be traversed by a periodic current identical with that passing through the inductive resistance. The movable coil of the wattmeter will be traversed by a current which will be in step as regards phase with the potential difference between the ends of the inductive circuit. When the dynamometer thus has its two circuits traversed by two currents, the force required to hold the movable circuit in its normal position against the electro-dynamic forces, is at any instant proportional to the product of these currents. If then the currents vary from instant to instant, and if the time of vibration of the movable coil is very long compared with the periodic time of the current, the mean value of the force required to hold the movable coil in its normal position with its axis at right angles to that of the fixed coil, will be proportional to the mean value of

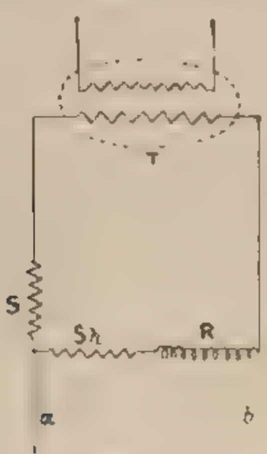

Fig. 3.

the products of the currents in the fixed and movable coils respectively—that is to say, will be proportional to the mean power being taken up in the inductive circuit. The force required to hold the movable coil in its normal position may be furnished by the torsion of a spring, and hence we can with such an instrument read off the mean power being taken up in the inductive circuit, provided that the wattmeter is already standardised. The best way to standardise the wattmeter is to apply the wattmeter to measure the power taken up in a known standard non-inductive circuit, and, at the same time, to measure the $\sqrt{\text{mean square}}$ value of the current flowing through this circuit and $\sqrt{\text{mean square}}$ value of the potential difference between its ends. In this way we apply the wattmeter to measure the known power being taken up in a non-inductive circuit, and we then obtain the constant of the instrument.

The conditions of success in the use of this wattmeter are as follows:

1. The current through the series coil of the instrument must have the same value as the current through the circuit to be measured, and the current through the shunt coil of the wattmeter must be exactly in step with the difference of potential between the ends of that shunt circuit; in other words, the shunt circuit must be strictly non-inductive. This can only be secured by winding the movable coil of the wattmeter with no very great number of turns.

On the other hand, we then have to face another difficulty when we employ such a wattmeter to measure the power taken up in the primary circuit of transformers at high pressure. In this case, in order to obtain the sufficient magnetic moment in the movable circuit of the wattmeter, we are obliged to pass a relatively large current through the shunt circuit, and then we find that we are wasting a large amount of power in this shunt circuit. Unless this power is at disposal, it may prevent us from practically employing this method. But fortunately there exists another method of dealing with the matter.

In my first lecture I pointed out to you that when a transformer is being worked on open secondary circuit, or is very lightly loaded, the potential difference between the ends of the primary circuit is exactly opposite in phase to the secondary circuit of the transformer, of which the primary circuit is connected to the extremities of the circuit in which the power to be measured is taken up (see Fig. 4). We shall still have an arrangement in which the current in the shunt circuit of the wattmeter can be made to be in step with the potential difference between the ends of the inductive circuit, all other arrangements remaining the same, but in which the total power taken up in the wattmeter is very much less than in the former case.

Fig. 4.

To show the difference between these two methods let us suppose that, in the first place, the wattmeter had a shunt resistance which could carry suitably one ampere, and that it is required to use this wattmeter to measure the power taken up in the primary circuit of the transformer at a pressure of 2,000 volts. We should then have to provide a non-inductive resistance capable of carrying one ampere at 2,000 volts, or nearly 2,000 watts expended on it. Under these circumstances, the power wasted in the shunt circuit of a wattmeter would be nearly 3 h.p. If, however, we do away with the non-inductive shunt resistance and take a 1 h.p. transformer capable of transforming down from 2,000 to 100 volts, and put the shunt coil and the wattmeter together with a small additional resistance across the secondary terminals of this transformer, so arranging the resistance that still one ampere flows through the shunt circuit of the wattmeter, we then have the following power absorptions:

The wattmeter shunt circuit will absorb 100 watts, and the transformer can be made to take as little as 60 or 70 watts, hence the whole arrangement—transformer, wattmeter, and additional resistance—only takes up 150 watts instead of 2,000; in other words, a saving of $92\frac{1}{2}$ per cent.

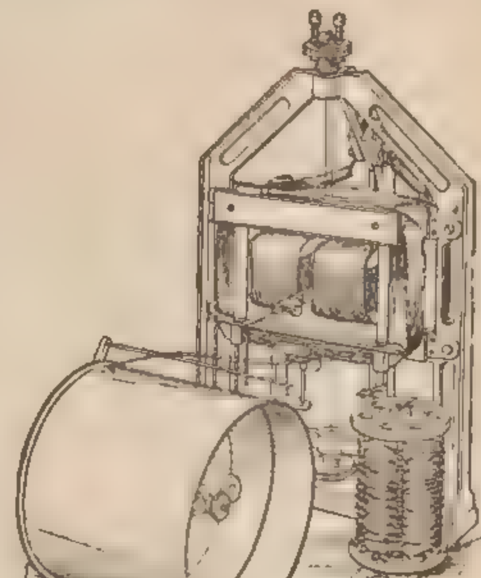

Fig. 5.—Mengarini Wattmeter.

It is clear, therefore, that the combination of the wattmeter with the transformer in this fashion is more economical than the use of a non-inductive external resistance. Generally, we may then say, that for the purpose of measuring alternating current power, the best instrument to employ is the dynamometer wattmeter; using either one of the Siemens form, in which the torsion of a spring is employed, or a balance form similar in construction to the ampere balance of Lord Kelvin. In those cases in which the

potential differences between the ends of the circuit in which we wish to measure the power absorption does not exceed 100 volts the whole, the necessary resistances can be placed in the movable coil itself, winding it at a high resistance, so that we have as few turns as possible in that coil and yet obtain the necessary magnetic moment. We can then apply the wattmeter, standardised as above described to measure the power taken up in any circuit inductive or non inductive. Many such instruments, lent by Messrs. Siemens Bros., Messrs. James White, of Glasgow, and others, are before me on the table.

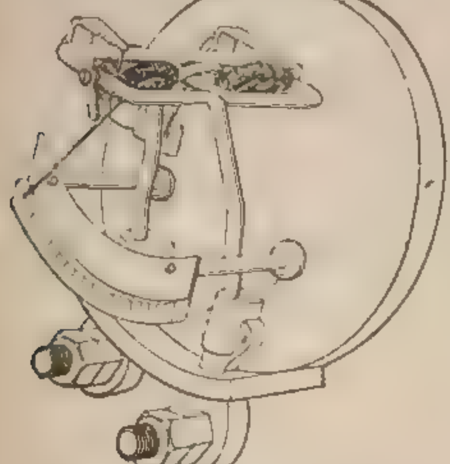

Fig. 6.—Engine-room Wattmeter.
General view of instrument, with case removed.

When we have to measure the power taken up by any inductive circuits, particularly when we are employing high pressures, as in measuring the power absorption in the primary circuit and transformers, then the best method to adopt is to use a transformer in connection with the dynamometer wattmeter, as above described. There is before me one interesting and novel form of wattmeter for use on alternating current circuits, which has been lent to me by Lord Kelvin. The instrument consists of a coil of one or two thick turns of copper wire, and a spectacle shaped fine wire coil in series, with an external resistance The instrument is adapted as a central station wattmeter, giving indications of power passing through it by means of the movement of a needle attached to the fine wire coil over a scale.

The interior is shown in Fig 6. It has a main circuit formed of a double rectangle of copper rod having sufficient area to carry 200 amperes, and a shunt circuit with two fine wire coils astatically arranged The main coil is mounted on a slate back, so that the rectangles are horizontal. The shunt coils are mounted on a light but strong aluminium frame in the manner shown in Fig. 7. One end of this frame has a circular knife edged hole fixed to it, and the other end has a straight knife edge. These two knife edges rest on two phosphor bronze hooks attached by insulating supports to the outside ends of the double rectangle By this method of suspension complete freedom from friction is obtained, while the movable system is kept in a definite position without end guides.

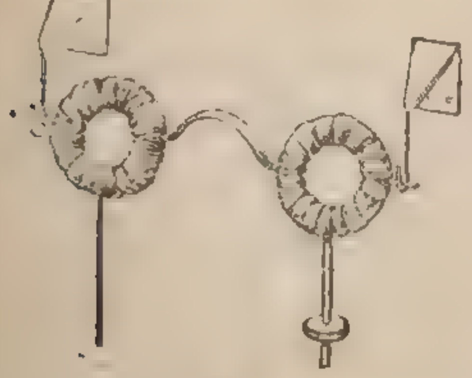

Fig. 7.
View of fine wire shunt coils, showing details of suspension springs removed.

Each fine wire coil has about 1,000 turns of insulated wire, and its resistance is about 100 ohms. The current is conducted in and out from the movable system by two flat palladium spiral springs, which also supply the restoring force for governing the sensibility of the instrument. Not more than $\frac{1}{10}$th of an ampere is allowed to pass through the fine wire circuit, and in order to regulate this a large non inductive resistance is rolled on the case of the instrument, which offers a large cooling surface. The scale has nearly uniform divisions, and is graduated to read directly in watts or kilowatts as required.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—The receipts for the week ended August 25 were £2,810.

School Offices.—The new and extensive School Board offices now being erected on the Thames embankment should be lighted by electricity.

Woolwich.—Messrs. Reid Bros., of 12, Wharf-road, City-road, N., are now completing the laying of mains for the electric lighting of Woolwich.

Tokio.—The Yokohama Electric Light Company's dividend for the half year is 5 per cent., and the Tokio Electric Light Company has declared 7·6 per cent. for the half year.

St. Pancras.—The St. Pancras Vestry have accepted the tender of Messrs. Johnson and Phillips for their "D. P." accumulators, for the extension of the Regent's Park central station.

Thames Conservancy.—The new offices of the Thames Conservancy on the Victoria embankment are approaching completion. Who intends to secure the contract for wiring the buildings?

Personal.—Mr. Robert Hammond has been appointed consulting electrical engineer to the Corporations of Newport (Mon.) and Wakefield, to carry out the electric lighting work under the provisional order.

Aberdeen.—The Gas Committee of the Town Council have agreed to instruct Mr. Murray, the electrical engineer, to go to London for a week to inspect the plant that is being made for the new electric lighting station.

Marine Signals (Barker's) Syndicate, Limited.—This Company has been registered with a capital of £6,000 in 5s. shares to carry into effect an agreement and to carry on business as engineers and signal manufacturers.

Partnership.—A gentleman desires to purchase or take a share in an established London electrical business. Communications on the subject are to be sent by principals (or solicitors) to Chas. Richardson and Co., 342, Strand, W.C.

City and South London Railway Company.—The receipts for the week ending August 27 were £716, against £805 for the same period last year, or a decrease of £89. The total receipts for the second half year of 1893 show an increase of £438 over those for the corresponding period of 1892.

Richmond.—The 30 men employed in the construction of the electric light undertaking at Richmond, and who went out on strike a week ago in protest against the dismissal by the engineer of three of their number without reference to the foreman, returned to their work on Tuesday morning.

The City.—At the fortnightly meeting on Tuesday of the Guardians of the City of London Union, the Thavie's Inn Committee reported that they had resolved to leave the matter of the electric lighting tubes, found under the paving near the walls next Robin Hood court, in the hands of Mr. W. M. Cross and Mr. Boyle, with power to confer with the clerk and architect thereon.

Getting Too Busy.—On enquiring recently as to the prospects of business, one very prominent company which manufactures and contracts for the equipment of central stations seemed to think that they were going to have really more work than they could get through in the time, and might be compelled to ask for a little indulgent delay from their customers, so long as there are only 24 hours in the day.

Derby.—The Chairman of the Derby Gas Company, speaking at the half yearly meeting on Wednesday, said that the electric light had been introduced into the town, and that before the next half year it would be in many of the shops. That might have some effect upon the gas company, but he was not afraid of it, and he could assure the company it would not affect the maximum dividends at present.

Testimonial.—We are informed that Mr. Vincent Swindells, who has been connected with the New Telephone Company at Manchester, and with its predecessor, the Mutual Company, from its commencement, has been presented with a handsome testimonial by his late colleagues on the occasion of his resignation. Mr. Swindells will now represent the Fowler Waring Cables Company in the North of England.

Lighting at Burnley.—The electric light station commenced to supply current for the first time last week Two large lamps in the centre of the town were the first to be lighted. The new illuminant has not yet been used at the Town Hall, but it will be in operation in a few days. A search-light will also be placed on the top of the Town Hall. The current has been switched on to the shop circuits, and various tradesmen's premises are now electrically lighted.

Huddersfield.—An installation of the electric light has been fitted in the Huddersfield Parish Church. While the church was being fitted with the light it was also cleaned and decorated, and the general improvement effected in the appearance of the edifice has been very marked We understand that the Huddersfield suburban extension of the municipal station is now being proceeded with, and that Messrs. Reid Bros., of 12, Wharf-road, City road, London, N., are the contractors for the work.

Government and the Telephones.—In the House of Commons on the 28th ult., Mr. Arnold Morley, replying to questions by Mr. Maclure and Captain Bagot, said the particulars of the agreements between the Post Office and the National Telephone Company were now under the consideration of the Government and he trusted that no undue delay would arise in [illegible] agreements. When the trunk lines were un[illegible] Post Office no priority would be given to an[illegible]

Shiplighting.—We are informed that Messrs. W. C. Martin and Co., electrical engineers, of 342, Argyle-street, Glasgow, have obtained a contract for the lighting of the new Leith and London steamer. The installation is to comprise 200 lamps and duplicate engine and dynamo. The same firm have also received the contract for the installation to be fitted on the ss. "Stirling," now being constructed by Messrs. W. B. Thomson and Co., Limited. Messrs. Martin and Co. have also a contract for the fitting up of electrical machinery on board two steamers now building at Belfast.

Lighting of Rolling Mills.—We understand that Mr. T. Scott Anderson, of Royal Insurance-buildings, Sheffield, has recently obtained orders from three of the largest rolling mill firms in Sheffield to put up complete installations, and that the workmen highly appreciate the arrangement of 300 c.p. incandescent lamps near the rolls. Mr. Anderson has now in hand a large installation for a wire rolling mill, and which will comprise 13,000 lamps. This will be the largest installation in the town. A complete plant for a dairy has also been supplied for the operation of cream separators, churns, etc.

Chertsey.—At a meeting last week of ratepayers, the chairman mentioned that a resolution was passed last year requesting the inspectors to enquire the terms upon which the area could be lighted by electricity, and report to a meeting as soon as possible. He wanted to know whether any enquiry had been made, and, if so, why the inspectors had not reported to the meeting as stipulated in the resolution. Mr. Webb replied that they had advertised, and had received several replies, but owing to red tapeism, provisional orders, and so on, they were not prepared to report at the present time, although an offer had been made conditionally by a corporation.

New Swindon.—During the meeting held last week of the members of the Local Board the question of gas and electricity came up. Mr. Jones suggested that a statement should be prepared of the cost of gaslight in the district up to Midsummer Day last, so that the members might have it for reference when dealing with the question of electric light. The Vice-Chairman said in that statement they would have to take into consideration that part of the district comprising new streets which were not at present lighted with gas. Mr. Fox said this matter had been fully discussed by the committee, and he did not think it was necessary to go further into the matter at this stage.

Edinburgh.—A meeting of the Sub-Committee of the Cleaning and Lighting Committee of the Town Council has been held with reference to the electric light installation at the Powderhall destructor. It was arranged that the destructor should be opened with some sort of ceremony on the evening of September 11, and that the Lord Provost should turn on the electric light at eight o'clock. In addition to members of the Corporation of Edinburgh and their friends, members of the Leith Corporation and other persons interested are to be invited to the ceremony. The destructor is being gradually got into working order and is even now disposing of about 40 tons or more of refuse in the 24 hours.

Europe and Azores Telegraph Company.—This Company has been registered with a capital of £200,000 in £10 shares. The object is to acquire a concession granted by the Government of Portugal to the Telegraph Construction and Maintenance Company, Limited, for the establishment of a submarine telegraph cable between Portugal and the Azores Islands, and for the laying of like cables between certain of those islands; to acquire and turn to account patents and inventions relating to telegraphy, and to construct, maintain, and work telegraphs, telephones, and electric light works, etc.; to manufacture telegraph and telephone wires and cables, and to carry on the business of telegraphy and the transmission of messages in all its branches. The first signatories are Sir J. Pender, G.C.M.G., M.P., Marquis of Tweeddale, T. Fuller, A. J. Leppoc Cappel, K.C.I.E., J. D. Pender, W. Shuter, and G. H. Richards.

Scarborough.—The Scarborough Electric Supply Company, Limited, commenced the supply of electricity on Saturday. At present the current is only available in a portion of the town, but the remaining connections are being completed as fast as possible, and it is expected that in the course of a week or two the whole of the mains will be completed. The company was formed at the end of last year by Mr. A. A. C. Swinton, under an agreement with the Corporation of Scarborough, and is working under a transfer of the provisional order obtained by the Corporation. The high-tension alternate current system, with low-tension distribution from sub-stations, is employed. The charge for electricity is at the rate of 7d. per Board of Trade unit, with a cash discount and a sliding scale rebate amounting to 20 per cent. as a maximum for large consumers. Colonel R. F. Steble is chairman, and Mr. A. A. C. Swinton, managing director and engineer-in-chief to the company. The electric generating plant and transformers have been supplied by Messrs. C. A. Parsons, of Heaton Works, Newcastle-on-Tyne.

Elmore Copper.—In a letter published in the *Financial Times* of Wednesday, "O. O." states: "Can nothing be done to make the Elmore Foreign and Colonial Company redeem its public guarantee to the preference shareholders, and pay the first year's interest of 10 per cent. They paid the first half on November last. The second half was due on May 1. No more has been paid. I parted with my £100 upon the direct representation of the company that they would pay the first year certain, and even this, with the usual consistency and truth that characterise all their statements, they represented would not be required of them, as the French Company would have almost unlimited means to pay *all demands out of profits* without calling upon them. Now, sir, *when you apply to the company they try to shift* their obligation upon the New French Company, 'who, by the way, I should like to hear something about,' and say they are pleased to say that with the new company provision has been made for the outstanding dividend due. I trust that some shareholders will bestir themselves, and through your columns bring these persons to account."

Mining Machinery.—The Jeffrey Manufacturing Company, who have had over 20 years' experience in the manufacture and application of mining machinery in the United States, have decided to introduce their machines to the colliery proprietors of Great Britain. Mr. Job, a mining engineer of great experience in machinery for developing coalfields in the States, has recently visited this country to ascertain the conditions and requirements of the various seams and methods of working, and has now returned to the States to have the machine modified to suit the "long wall" system of mining. The types of machine which have survived the experimental stage are that for undercutting coal which takes a cut 3ft. wide and up to 6ft. deep in about 20 minutes, and a drill which bored a hole for blasting 2in. diameter by 6ft. deep in about two minutes. The English business will be worked by Messrs. John Davis and Son, of Derby, London, and Cardiff, who have undertaken the management for the United Kingdom. The motive power is usually electric, and the machines for safety lamp pits will be fitted with the Davis and Stokes safety motor.

Bath.—At the fortnightly meeting of the Sanitary Committee of the Town Council, Mr. H. A. Simmons complained of the nuisance caused by the smoke from the electric light works. The inspector said on the 24th ult. he served a notice on the company to abate the black smoke nuisance within four days, and also one giving them seven days to make the furnace apparatus perfect. The company had ceased to use a smoke consumer they formerly had in the chimney. A letter from the manager stated that the company had been unable to get smokeless coal owing to the strike, and that if the notice were followed up the plant would have to be shut down and the supply of light to the city discontinued. It was decided to call upon the company to replace the smoke consumer, but not to take other steps for the present. **At a meeting of the Surveying Committee of the Town** Council, Mr. Gatehouse's charges of £50. 4s. for examining the electric light for the half year were presented. Mr. Taylor asked whether the examination was carried out at the works or at Mr. Gatehouse's offices. Although the machinery for testing might involve some expense, he thought it would be more satisfactory that he should make the examination at his offices than at the works. Mr. Sturges promised to bring up a report on the matter at the next meeting.

Electric Lighting for Dewsbury.—Mr. F. H. Tulloch, one of the inspectors of the Local Government Board, held an enquiry on Tuesday at the Town Hall in respect to an application made by the Dewsbury Corporation to borrow £25,000 for electric lighting. The Mayor of Dewsbury, and several members of the Corporation, and Mr. A. H. Preece, son of Mr. W. H. Preece, engineer, of London, were amongst those present. The Town Clerk (Mr. E. Mawdesly) said the Council had come to the conclusion that an installation of the electric light was necessary in the interests of the town, and they found there was a demand for it. They sought the best possible advice, and Mr. W. H. Preece, of the Post Office, London, drew up specifications. Tenders had been accepted, and in mentioning that the successful firms were Messrs. Siemens and Co. for street main work, Messrs. Crompton and Co. for engines and generating plant, and Messrs. Horsfield for supplying boilers, he thought that was sufficient evidence of the works being satisfactorily carried out. The Corporation did not propose to expend the whole of the £25,000 immediately. It was thought the present system of lighting the streets with gas was sufficiently good. The Corporation had expended large sums of money on the gasworks, yet they believed that by adopting the best possible system of electric lighting, and at a price which would enable persons to become customers, there would be a profit which would counteract any loss from the gasworks. There was no opposition, and after Mr. A. H. Preece had explained the extent of the scheme the enquiry was concluded.

Bristol.—The question of insuring the new buildings was under the consideration of the Electrical Committee of the Town Council at their last meeting. Mr. Kapp, one of the consulting engineers, and Mr. Henry Williams, the architect, were present at the meeting, at which it was reported that no fewer than 30 tenders had been received from different insurance offices, but the rates quoted by some of the competing companies were much higher than was anticipated by the committee. This led to a suggestion that it would be advisable for the Corporation to themselves establish a system of insurance for all their property, but no definite proposal arose out of the discussion, and at length it was decided to effect an insurance upon the building itself. Some appointments were made on the electrical staff, and it was left to Mr. Kapp and Mr. Faraday Proctor to recommend two candidates for appointment as assistant engineers. At the industrial exhibition opened this week, one of the chief attractions is the prismatic fountain in the art section. The jets consist of a heavy and copious one in the centre, 20 mist jets immediately surrounding it, 16 straight jets a little farther removed, and a number of spray jets affixed around the border of the fountain. At the eastern end is also a prettily arranged cascade. In all there are five separate sources of water supply. Underneath the central jets is a series of 16 watertight boxes, and there is a large lantern in the roof exactly over the central stream. The electric lights and coloured screens in these and the jets of water are controlled from a chamber in the south gallery, where by means of ingenious contrivances the streams can be raised or lowered, and otherwise

varied, and the lights can be manipulated so as to produce the most charming effects. The electrical work of the fountain has been well and admirably carried out by Messrs. F. W. Ball and Co., Bristol.

Cable between Australia and America. Mr. Hogan a few days ago asked the Postmaster General whether he had observed in a daily paper a despatch from Berlin stating that the cable from Australia to New Caledonia, constructed by a French company, was the first section of a cable service from Australia to America *via* Samoa and Honolulu, and that the German Imperial Post Office had expressed its readiness to grant a subsidy towards the construction of the Samoan connection; whether he had any information that would throw light on this alleged intention to construct a complete cable service under foreign management and control between Australia and America; and whether any steps had been or were being taken to give effect to the strongly expressed wishes of the Australian and Canadian delegates to the Imperial Conference held in London in 1887 in favour of the construction of a Pacific cable under British management and control. Mr. A. Morley: The answer to the first paragraph of the hon. member's question is Yes, but I have no official information which bears out the statement. As to the second paragraph, the agreement which has been entered into by the French Government with a company for a cable from Queensland to New Caledonia has been published, and I shall be glad to let the hon. member see a copy if he wishes. I am not aware of any steps having been taken to lay a cable under British management and control, but I ought to add that, as subsidies to submarine cable companies are not borne on the vote of the Post Office, the question is not one under my special control.

Babcock and Wilcox, Limited.—The second ordinary general meeting was held on Wednesday, at Cannon-street Hotel, E.C., Mr. Andrew Stewart, the chairman, presiding. The Chairman said that they had paid to the shareholders for the half-year ended December 31 last an interim dividend of 10 per cent. on the ordinary and 6 per cent. on the preference shares, which absorbed £10,000. They now proposed to pay 10 per cent. on the ordinary shares and 6 per cent. on the preference, absorbing £10,000, the total dividends payable for the year being £20,000. They had, in addition, written off the sum of £11,328 for the purchase of business account, and would carry to the credit of next year the sum of £9,547. The plant and machinery were kept in an efficient condition for the economical and successful production of the patent boilers, and, to still further aid that purpose, they have made additions to plant account for last year amounting to £1,913. They had, as compared with last year, not been able to obtain the same success financially, due to the very bad trade and the scarcity of orders in every market open to their efforts at home and abroad. Still, they considered the results and the income earned as, on the whole, very satisfactory. The three most gratifying facts in the directors' experience during the past year had been, first, the steady progress which the boiler was making in the old markets into which it had been introduced, and the favourable returns from the new markets which they had been and were exploiting; the second was still more important, viz., the high appreciation of the boiler by those who had been using it, the fact being that not less than 50 per cent. of the orders coming in were from those who had used the boilers before; the third was the progress making in improvements on the boiler and auxiliary matters connected with it, which they believed would keep it well ahead of manufacturers of boilers working in the same direction, largely due to the excellent staff employed, but still more to the able management of the acting directors. He then moved the adoption of the report and accounts, and the payment of the dividends. The resolutions were carried.

Lighting of Aberdeen.—It is more than 10 years since the subject of the introduction of the electric light into the city of Aberdeen was mooted at the Aberdeen Town Council, but it was not until 1890, when the Aberdeen electric lighting order was obtained, that any real progress was made. By that order power was taken to supply the whole city with the electric light, but the compulsory area which the Corporation in the first place undertook to supply was limited to Union street (from the Town House westward to Bridge street), Market street (between Union street and Guild street), Broad street, St. Nicholas street, School hill, and Union terrace. The whole scheme was to be worked in conjunction with the gas undertaking, an arrangement which was, on the face of it, the most economical and efficient that could be devised. In July, 1892, there was submitted to the Town Council an elaborate report by Prof. Alexander B. W. Kennedy, F.R.S., M.I.C.E., on the best method of supplying the electric light to shops, offices, public and private buildings in the city, the lighting of the streets not being then in contemplation, although provision has now been made for its introduction at a future period. That report formed the basis of the system which was finally adopted by the Town Council and which is now in process of installation. The system adopted is one by which the electrical energy is generated at a station in the immediate vicinity of the gasworks, and distributed to the area already referred to by means of copper strips resting on porcelain insulators, and laid in a concrete culvert. In order to provide for the 7,000 lamps which it is proposed to supply with the electric light within the area, the station in Cotton street is in course of erection. This building is planted within the grounds of the gasworks, and can thus be economically supplied with coal for the works by the waggons and locomotive which run past the building. The station consists of three main parts—the boiler room, the engine and dynamo room, and the switchboard room, occupying the upper part of the building. There are in the basement four Babcock and Wilcox boilers, which supply the engines with motive power. There are five engines, three of these being each of 80 h.p., the other two being capable of indicating 40 h.p. The five engines drive the dynamos direct. In another part of the building are the storage cells. Including all the buildings and plant the cost of the installation may be roughly estimated at £24,000. The entire cost will fall on the gas undertaking of the city, and it will take some time before the whole area is supplied up to the capacity of the engines and dynamos at the central station. When the whole 7,000 lamps are in operation, the Council will probably be prepared to face the further extension to the western district of the city, which will be accomplished at a further cost of about £20,000. When the installation is complete the central station will be able to supply 10,000 lamps of 8 c.p.

Kelvinside Central Station.—The directors of the Kelvinside Electricity Company, Limited, invited, on Monday, a select company to be present at the starting of the Kelvinside electric light station, Hughenden road. The Act of Parliament confirming the rights to supply electricity to the district of Kelvinside was granted at the same time as the Glasgow Electric Lighting Act, but not having the financial resources of a city at their back the company have not been able to get into working order quite so quickly as Glasgow. The few months' delay, however, in opening has enabled the company to profit by the experience, not only of Glasgow, but of various other towns having electric lighting in progress. The result is seen in the supply station now ready for work. The buildings are situated about 100 yards north-west from Hyndland road railway station, and are built of a fine quality of brick, specially selected for its pleasing red colour. The works are so designed that the portion now built, while in itself complete and perfectly equipped, forms only a part of a larger station, the completion of which can be accomplished without interfering with the part already at work. The coal bunkers, of about 6,000 cubic feet capacity, are so placed that coal can be obtained direct from the railway waggons, and so constructed that the coal falls towards the furnaces, and is delivered at the furnace mouth with the minimum of handling. Provision is made in the complete station for 10 high-pressure boilers of 150 h.p. each, two of these boilers being already in position and under steam. The portion of the engine and dynamo room now built measures 67ft. long by 25ft. broad by 31ft. high. The foundations already in are suited for six engines and dynamos of 120 h.p. each, two of which are in operation. Each of these can supply 1,500 incandescent lamps of 10 c.p., or 1,000 of 16 c.p. In addition there are in an adjoining compartment accumulators of the largest type made. A gallery, which runs the whole length of the engine room, contains the switchboard and instruments mounted on white marble panels, and leads to the store room. Underneath the station a subway gives access to the conductors between the dynamos and switchboards and to the end of the feeder mains which carry the current over the Kelvinside district. Over 10,000 yards of feeder and distribution mains are already laid under the streets from which the earliest demand is expected. Houses are already wired for a total of 1,500 lamps of 16 c.p., and a number of others are in progress or under negotiation. The area over which the lighting extends is bounded on the east by Byres road, the west by Bingray road, the north by Winton drive, and the south by Dowan hill. The buildings and the installation generally have been designed by and carried out under the superintendence of Mr. John M. M. Munro, M.I.E.E., of the firm of Anderson and Munro, of Glasgow, and Messrs. Sharp and Kent, of London, have been the contractors for the whole work, their representative being Mr. Elsden Dew, A.I.E.E. The switching on ceremony was performed by Miss Elsie Munro.

Windsor and Eton. Mr. A. E. Farrow has written to the *Windsor Gazette* as follows: "The provisional order granted to the Windsor and Eton Electric Light Company embraced too large a district to prove remunerative to its shareholders, and had the company laid mains all over the area which the provisional order included, Windsor would be in the unenviable position of having by far the least number of lamps per mile of main than any supply company in existence. Datchet, which is included in the order, is too far from Windsor, and the demand for electric light is also too small to prove in any way remunerative. Assuming there is a demand for a thousand lamps in Datchet (which is about the number required there), to supply them from Windsor means laying down duplicate high-tension dynamos at the works here, and an expensive $2\frac{1}{2}$ miles of highly insulated cable, also a station at Datchet, with motor transformers and accumulators to supply the customers there with low-tension electricity. If alternating currents were employed, it would mean a double set of men in the station at Windsor to comply with the regulations of the Board of Trade. Regarding the supply, the best system of electric light to adopt in Windsor would be the low-tension three-wire system; as the consumers are all within a half-mile radius of the supply station, assuming, of course, that the new works will be where the old ones are. The station ought to be built to be able to contain enough machinery for 9,000 lamps, and equipped with the necessary engines and boilers for 3,500 lamps, which there is an immediate demand for. The additional machinery could be installed as required. The approximate cost of building the above, with all necessary boilers, engines, dynamos, accumulators, etc., for 3,500 lights of 8 c.p. would be about £9,000. To lay down mains from supply works to Peascod street, along up Peascod street to High-street, down Peascod street to Osborne-road, to extend along High street to the lower end of Frances road ... street, also down Thames-street to Windsor ... should be laid with enough copper to ...

should also have necessary feeders to keep the pressure as near as possible constant These would form the principal mains, and less expensive ones could be laid in the side streets whenever required The cost of mains, including the laying down in the above streets, would be about £4,000 Thus, with the purchase of land, law and incidental expenses, the cost would be about £14,000 As to the income to be derived from the sale of electricity, of course the first year the station would only about pay its expenses, but it is certain that in the second year there would be quite 3,500 lamps on Now, a fair average consumption of electricity for an 8 c p. lamp per year is 25 units, so that 3,500 lamps, taking 25 units each per year at 8d. per unit means £3,750; the cost of the works would be about 4½d. per unit; there would therefore be a saving or profit of £1,693. Of course, as the demand increased, the price per unit would be less, and if street lighting with arc lamps were introduced, the works would pay a very good dividend."

Electric Lighting at Taunton. On the 22nd ult. the report of the Electric Lighting Committee was presented at the meeting of the Town Council It was as follows "The committee recommend that the purchase of the electric lighting works be completed on September 30 The committee recommend that some practical electrical engineer be appointed to advise the Corporation as consulting engineer They herewith present a letter from Dr J. A. Fleming, offering to act in that capacity for 12 months for 25 guineas and travelling expenses The committee recommend that he be appointed accordingly Your committee have instructed a sub-committee to consider several matters and report to the Council thereon The sub-committee report as follows: They recommend that the services of Mr Henry Everard Hunt, the electrical engineer, be continued at his present salary of £150 a year, subject to three months' notice on either side. That Mr Hunt be allowed to take such pupils as the committee shall from time to time consider advisable, and that one half of their premiums be paid by him to the Town Council That engine drivers, stokers, trimmers, and labourers be under the control of the electrical engineer for the time being, subject to the approval of the committee. The sub-committee have instructed the borough surveyor to check with Mr. Hunt the places for stores with the inventory taken while negotiations were being made for the purpose of the works They recommend that advertisements and notices be given stating that the Council are prepared to receive at once applications for the 1st day of October next. They also have recommended that as the duties as Electric Lighting Committee will cease as soon as the purchase of the works is completed, a committee be now appointed to make arrangements for carrying on the business of the electric lighting works after the time, and that such committee be authorised to consider such arrangements at once." Alderman Chapman, in moving the adoption of the report, remarked that they had passed from the stage of general discussion as to whether they were right or wrong in acquiring the electric light works. It now became their duty to pass such resolutions as were necessary to carry on the works and other matters of detail. As regards the date for completing the purchase it was suggested to be the 30th September, to allow sufficient time for the preparation of the necessary deeds, and also as being a convenient date for the change to take place It was also suggested that advertisements be issued to inform the public that the electric light would be supplied after a certain date. That should be done because it was understood that some people had been waiting to know when it could be done. There was an erroneous opinion abroad that the light could not be carried to the extreme parts of the borough, it should be known that the system was sufficiently powerful to carry the current as far as the Wesleyan College on Haines Hill. The report was adopted. In place of the old committee the following gentlemen were appointed as the Electric Light Committee to manage the works: Messrs. Van Trump, W. M. Chapman, A. Goodman, W. Potter, A. Hammett, A. Steevens, J. Goldsmith, R. U. Hartnell, and J. P. Sibley.

PROVISIONAL PATENTS, 1893.

AUGUST 21.

15781. **An improved system of electric wiring.** Thomas Pattison Rennoldson, Banbridge, co. Down, Ireland

15789. **An automatic method of starting and stopping the paper of Morse telegraph or other recording instruments.** John Peter Gorton, The Commercial Cable Company, Weston super-Mare.

AUGUST 22.

15906. **Improvements in and relating to electrolytic apparatus.** David Young, 11, Southampton buildings, Chancery-lane, London. (La Societe Oatheme Chalandre Fils and Cie., France.) (Complete specification.)

AUGUST 23.

15907. **Improved insulator for telegraph and telephone wires.** Henry Koster, 9, Warwick court, Gray's inn, London.

15938. **Improvements in telephones.** Alexander Spark, 4, Belmont street, Aberdeen.

15957. **Improvements connected with assistant or auxiliary electromotors.** La Societe Anonyme pour la Transmission de la Force par l'Electricite, 6, Lord street, Liverpool. (Date applied for under Patents, etc, Act, 1883, Section 103, 15th March, 1893 being date of application in France.) (Complete specification.)

15962. Improvements in electric indicators. Berthold Zeitschel, 40, Chancery-lane, London. (Complete specification.)

AUGUST 24.

15971. **Electromagneto motor for maintaining uniform speed.** George Lee Anders and Walther Kottgen, 10, Jeffreys-square, St. Mary's axe, London.

15974. **A new form or construction of tube or pipe for carrying or supporting electric wires underground.** John Johnston Green and William Oates, Commercial-street, Halifax.

15997. **Improved electric high-tension fuse head for use in blasting.** Tom Malson, Sidney Richard Malson, William Albert Malson, and Emmanuel Smith, 3, Chichester rents, Chancery lane, London (Complete specification.)

16000. **Improvements in telegraphy** Charles Arthur Allison, 52 Chancery lane, London (Pierson J. Wicks, United States (Complete specification.)

16008. **Improvements in or relating to multiple telegraphy.** Alfred Piedfort, 323, High Holborn, London. (Complete specification.)

16017. **Improvements in electrically-actuated machine tools.** Henry William Gibbs and George James Gibbs, 4, South-street, Finsbury, London.

16019 **Improvements in metal posts or supports for electric wires or cables, also applicable for other purposes** Oscar Andre, 24 Southampton buildings, Chancery lane, London. (Complete specification.)

16025. **Automatic coupling for electromotors** Siemens Bros. and Co, Limited, 28 Southampton buildings, Chancery-lane London Siemens and Halske, (Germany.)

16026 **An automatic regulator for dynamo-electric machines.** Siemens Bros and Co, Limited, and Ernest Holmes, 28, Southampton buildings, Chancery lane, London.

16027. **Improvements in connections for local supply from electrical mains.** Siemens Bros and Co, Limited, and Harry George Knorr, 28, Southampton buildings, Chancery lane, London (Complete specification.)

16028 **A method of compensating variations of load at electrical stations** Siemens Bros and Co, Limited, 28, Southampton buildings, Chancery lane, London. (Siemens and Halske, Germany.)

AUGUST 25.

16060. **Improvements in electric arc lamps.** George Theodore Pardoe and George Broughall, 4, St. Ann's square, Manchester.

16074. **Improvements in apparatus for lighting gas by electricity.** Adolf Geyer and Johann Stegmeier, 37, Chancery lane, London. (Complete specification.)

AUGUST 26.

16133. **Improvements in electrical devices for opening doors.** William Phillips Thompson, 6, Lord street, Liverpool. (Hermann Schultze, Germany.) (Complete specification.)

16136. **Improvements in or relating to electrodes for primary and secondary batteries** Alfred Julius Boult, 323, High Holborn, London Rudolph Theodor Ernst Hensel, Germany.) (Complete specification.)

SPECIFICATIONS PUBLISHED.

1889

14867. **Electrical conductors.** Imray (Walton.) Second edition.)

1892.

14658 **Secondary batteries.** Smith.

17643 **Electric switches.** Edmunds.

17922. **Secondary batteries** King and Clark

24127. **Secondary batteries.** King.

1893.

2161. **Heating liquids by electricity.** Miller and Woods.

9039. **Autographic telegraph apparatus.** Denison.

9819. **Electric circuit controlling devices.** Hall.

11464. **Galvano-electric belt.** Thompson. (Biermann.)

11819. **Electric railway trolleys.** Allen.

12374. **Electric lamps.** Gover.

NOTES.

Poitiers.—The Blossac Park is to be lighted electrically.

Auterive.—A central station has just been set in operation.

Milan.—An electric railway is projected between Milan and Vilanterio.

Zermatt is to be lighted electrically by the Vevey Construction Works.

Theatrephones.—Several theatrephones have been established at Cardiff and Bristol.

Adding Apparatus.—An adding machine has been invented by Mr. A. Erskine Muirhead, of Glasgow.

Rome.—The Banca Nazionale in Rome will shortly be equipped with 11 electromotors for ventilating purposes.

Long-Distance Telephony.—Telephonic communication between Stockholm and Christiania was started on Saturday.

Caen.—A central station is to be built here, and the price for light will be lower than that charged for gas illumination.

Electric Locomotives.—Four of the principal French railway companies are said to be making experiments with electric locomotives.

Calais.—The Calais Gas Company has been granted a concession for the electric lighting of the town, the work to be completed by the end of November.

Private Bills.—Among the principal private Bills considered this session have been those for the extensions of the underground electric railway system in the metropolis.

Artificial Diamonds.—It is believed that M Moissan will exhibit at the forthcoming meeting of the British Association some artificial diamonds prepared in his electric furnace.

High Speed.—We wonder whether it is correct, as reported, that a locomotive, designed by Mr. M. Reynolds, of Wolverhampton, is now being constructed to run at 100 miles an hour.

Essen.—The electric tramway from Essen to Borbeck and to Altenessen, equipped by the General Electricity Company of Berlin, was opened to traffic on Wednesday of last week, 13 cars being put into service.

Copenhagen.—A new telephone station is being constructed for the Copenhagen Telephone Company. It will have accommodation for 10,000 subscribers, and arrangements are being made for a double-wire system.

Stettin.—The central station established here in 1889 by Messrs. Siemens and Halske was extended last year by the addition of two new dynamos and a battery of accumulators. There are now at work four engines of a total of 900 h.p.

British Museum.—The annual account and return of the British Museum states that preparations are being made for the installation of incandescent electric lamps in the reading-room, and which will be completed before the autumn.

Berlin.—The extension in the use of the electric light in private residences is attributed as the cause of a diminution in the consumption of gas in Berlin during the first quarter of the present year. This is rather surprising, as the converse is generally the case.

Refuse Destructors.—The Powderhall district of Edinburgh has been supplied with a refuse destructor, the heat from which, as mentioned last week, is to be used in connection with the electric light plant laid down on the spot for the illumination of the buildings.

Edison.—It is said that Edison's father, Samuel Edison, is now 90 years of age, and expects to live some years longer, as his father was 103 years old, and two aunts were 99 years respectively at the time of their deaths

Tramway Congress.—The sixth International Congress on Tramways and Street Railways was opened yesterday at Budapest. Among the subjects under discussion is the question as to the conditions under which electric power is preferable to animal or mechanical power.

Blackpool Tramways.—A report by the electric engineer to the Corporation states that the electric cars cannot be successfully worked on the present system. The line, he states, costs too much to maintain. The Council have been informed that it will be necessary to adopt some other system of working the cars.

Friend or Foe.—In a paper read before the Pacific Coast Gas Association, Mr. J. L. Hallett, of Portland, Oregon, dealt with the question as to whether the electric light was a friend or foe to the interests of gas lighting. He concluded that much depended upon the quality and price of the gas sold, and on considerate management.

Remscheid Tramway.—The electric tramway recently set in operation at Remscheid comprises two lines of a total length of about five miles. It is arranged on the Thomson-Houston system, and the gradients range from ·2 per cent. to as much as 10 per cent. There are five cars in service, and the number will shortly be increased.

Subways.—The members of the Manchester District Institution of Gas Engineers on Saturday inspected the subways at Nottingham. These subways have been constructed to contain the sewers, gas and water pipes, electric light mains, and telegraph and telephone wires, so as to render these readily accessible without breaking up the streets.

Torpedoes.—Arrangements have now nearly been completed for important experiments by the United States Navy, at Newport, U.S.A., for launching the Sims-Edison electrical torpedoes from a steamer at sea with a view to introducing it as a naval weapon. Torpedoes of this type were adopted three years ago by the United States engineers for coast defence.

May Island Lighthouse.—The Lord Provost of Edinburgh and other members of the Board of Northern Lighthouses, have accompanied two German officers to May Island to inspect the electric appliances in the lighthouse. The visit was in connection with the proposal of the German Government to establish the electric light on Ruegen Island in the Baltic.

Mutual Induction and Capacity.—Messrs. Bedell and Crehore, in a pamphlet reprinted from the *Physical Review*, discuss this question in the general case of two independent circuits each of which contains resistance, self-induction, and capacity, and which are connected only by means of their common magnetic field. The investigation is intensely mathematical.

The Douglas Tramway.—Some experimental runs are in progress with the electric cars. The tram line passes round the bold headlands at the north end of the bay as far as Groudle Glen, and will ultimately be continued to Laxey, a distance of 10 miles. The experiments are being carried on under the superintendence of Dr. Hopkinson, and have been witnessed with considerable interest. All the lines have been laid.

Antwerp Exhibition.—An electrical committee has been formed in connection with the international exhibition to be held at Antwerp next year. The committee has been divided into three sections: (1) Scientific applications and measuring apparatus, presided over by M. Eric Gerard; (2) industrial applications, transmission of power, lighting, and production of electricity, of which M. Beliard is president; and (3) telegraphy and telephony, M. Banneux being president.

Electricity vice Cable.—It is said—though with just what authority one would at this distance hardly care to decide—that all the cable tramways in the city of Denver, Colorado, have been gradually transformed, and are now operated on the electric trolley system. As the cables wore out, the tramway company in each case, it is said, substituted electric traction appliances instead of buying new cables, etc., and the result is claimed to be all one could wish on the score of economy and better service.

Belem.—The Municipality of Belem, Brazil, invite tenders for the lighting of the town either by gas or electricity, or by both. Intending contractors must consider the charge for the light, its quality and intensity, the system adopted for its production, distribution, and maintenance, the length of the concession, the time necessary for commencing and for completing the work, and the nature of the currency in which payment is to be made. Tenders are to be forwarded by the end of October.

Signalling from Balloons.—One of the important features of the autumn manœuvres will, it is said, be the trial of an improved organisation in military aeronautics. In addition to taking photographs at greater heights than have hitherto been publicly recorded, improvements have been made in day and night signalling—the latter by electricity—from balloons between various components of the same force. Of course these signals might be read by the common enemy, but it would be easy to change a code of signals so that it could be read to any purpose only by the initiated.

Electric Powers (Protective Clauses).—There has this week been published by Messrs. Eyre and Spottiswoode the report from the Joint Committee of the House of Lords and the House of Commons on Electric Powers (Protective Clauses), together with the proceedings of the committee, minutes of evidence, appendix and index. The substance of the report has already been given in this journal on the occasion of the holding of the enquiry and in subsequent issues. The report will, however, form a valuable work of reference.

To Gauge Trembling.—A device termed a "tromometre" has been devised by Dr. Quintard for gauging the trembling of nervous people. It consists of a metal plate pierced with 20 holes of different sizes in a graduated scale, and a needle which the patient endeavours to put into the holes. When he succeeds in placing the needle in a hole, he completes an electric circuit, causing a bell to ring. The excessive indulgence in coffee and stimulants, as well as lead or mercurial poisoning, produce tremblings which it is said can be tested with this apparatus.

Car Accident.—The daily papers this week head a paragraph as "Fatal Electric Car Accident in Cincinnati," when the fact that electricity was used as the motive power had nothing whatever to do with the accident. The car, as has happened on various occasions with cable and steam cars, was proceeding at a rapid rate down a steep hill when it left the rails, and almost immediately overturned. The car, which had a full complement of passengers, was wrecked, two passengers being killed, and 40 persons receiving injuries of a serious nature. Of course an accident of this kind may occur with almost any system of haulage, and the one in question should lead to generalising slow speeds in descending steep gradients.

Greenwich Observatory.—This observatory is now being lighted by electricity. Mr. W. H. Christie, the astronomer royal, is establishing the plant in the south wing of the new physical observatory, now nearly completed, in the grounds. A gas-engine, dynamo, accumulators, and main leads are now on the premises, and the installation will shortly be finished. Any possible effect that the generation of electricity might have on the magnetographs within 170ft. will be guarded against by a triple iron shield completely enclosing the dynamo.

Auer Incandescent Gaslight.—There has been considerable discussion in Germany and Austria among gas and electrical engineers regarding the advantages of the Auer incandescent gaslight. The German Polytechnic Society has endeavoured to ascertain whether the Auer lamp could be used in a dusty and moist atmosphere. In reply to a request for an expression of opinion on the subject, the German Incandescent Lighting Company said that in places where dust was plentiful it was not advisable to employ the Auer system, because the dust deposited itself on the mantle, especially when the lamp was not alight, and the illuminating power diminished. Then, again, when the mantle is cold, it absorbs moisture, and becomes deformed, and its lighting power in this case is also reduced.

Liverpool University College.—The prospectus of the day classes in arts and science and of the evening lectures for the session 1893-94 has been issued. The electrical engineering course is intended to impart a thorough knowledge of the principles involved in electrical engineering and practical acquaintance with the use of machines and apparatus, and to be followed prior to a student entering works or office. The course, which extends over a period of three years, comprises much the same curriculum for the first and second years as that for civil and mechanical engineering, with the exception of additional hours spent in the physical and electrotechnical laboratories. In the third year a larger proportion of time is passed in the latter laboratory and in attendance at lectures and classes on electrotechnics. A course of 11 lectures will be given on telegraphy.

Heilmann Electric Locomotive.—Writing last week to Mr. B. H. Thwaite, Mr. C. Brown, of Basle, states: "It may interest you to hear that the big electric locomotive was started last Monday; it runs wonderfully sweet, the faster she goes the smoother, the disturbing influences of the reciprocating masses being entirely eliminated. No counterweights in driving wheels, but a steady tangential pull at the tires. This added to the compensating action of the compound bogies, combined, produce a locomotive which runs with phenomenal smoothness. You can hold a glass full of water, standing on the driving platform, without spilling a drop, or even producing a ripple on the surface. The movement is even less than in a first-class Pullman. It quite took the breath out of the railway engineers on the footboard; they could scarcely believe their eyes, their other senses failing to impress them that the engine was actually running."

Electro-chemical Effects on Magnetising Iron.—In the *Proceedings* of the Royal Society, Mr. T. Andrews draws attention to the electro-chemical effects on magnetising iron. From a long finely-polished rod, two steel bars were cut adjacently, so that they were practically alike in

general composition and structure. These bars were both weighed, and then immersed in equal quantities of cupric chloride solution, one of them having previously been magnetised. After a certain time (six to twenty four hours) they were taken out of the solution, freed from deposited copper and carbonaceous matter, then dried, and again weighed. It was found in every case that the magnetised bar had lost more in weight than the unmagnetised bar. For instance, an average of 29 experiments showed an increase of corrosion in the steel due to magnetic influence of about 3 per cent. under the conditions of experiment. It may be mentioned that the bars were not highly magnetised.

Electro-Chemistry.—Mr. G. H. Zahn has investigated the phenomenon of the separation of precipitates at the boundary of electrolytes, and has given the results in the *Ann. Phys. Chem.* The current was allowed to pass through two solutions of the same salt of different concentrations, from that of the greater to that of the less, a separation of the hydroxide of the metal then taking place at the boundary of the two solutions in certain cases. Such a separation was noticed with salts of magnesium, calcium, barium, strontium, aluminium, manganese, iron, zinc, and copper; but not in the case of silver salts. In the latter case, however, as also with the salts of sodium and potassium, which form soluble hydroxides, the presence of the hydroxides at the boundary between the solutions could be rendered evident by the alkaline reaction of the solution with methyl orange at this point. The author is inclined to regard the above phenomena as evidence that water plays some part in the electrolysis of salt solutions.

Manchester Central Station.—Referring to the note in our last issue as to when electric light would be available from the municipal station, we are informed by Mr. H. Wooter, electrician to the Corporation, that the supply has been at hand, and has been accepted by consumers for night service between 5 p.m. and 12 midnight, since July 31. On that occasion the Free Trade Hall was switched on, and on the following day the Bank of England, the Union Club, and several other places were lighted. Since then, our informant observes, a number of additional consumers has been connected each successive day, until at the present time an equivalent of 6,000 8-c.p. lamps and some arc lamps are joined to the mains, whilst current is also supplied for motive power purposes. The Corporation are, moreover, dealing as quickly as possible with contracts already signed for 10,000 additional 8-c.p. lamps, over 100 arc lamps, various fans, motors, and for cooking apparatus. The demand for current is so great that continuous running commenced on the 1st inst. There has not yet been any official ceremony, because the normal working conditions of the five-wire system will probably not be brought into operation until the end of the month.

Electric Railways.—The recent report of the committee appointed to frame clauses for insertion in the Bills promoted by electric railways, says *Engineering*, emphasises the well known fact that there is a large amount of leakage when the rails are used as conductors for the current. When only one rail is used for this purpose the leakage is into the earth, and thence along any pipes or wires that offer an easy path. When the rails are used as the positive and negative conductors respectively, the leakage becomes very much more serious, and, indeed, is practically prohibitive of this method of working. The columns of our contemporary have contained accounts of several attempts to avoid this difficulty by carrying the current in buried conductors and connecting short lengths of rail to these at intervals, so that the leakage is localised. A more recent method, proposed by Lord Alfred Spencer Churchill, is to make connections to the buried insulated conductor every 20ft. or so, and at each to erect a special contact-piece above the roadway. On the vehicle is a brush so long that it will always touch one of those contacts, and thus always be in communication with the main conductor.

Just the Same Here.—Over in the United States it has been found that the great demand for competent electrical engineers who can prove themselves reliable and skilful has led to a great rush of beginners and students into the field with an idea that their fortunes will thereby be made. Mr. G. D. Shepardson gives the following timely advice to such: "The work of most electrical engineers is largely something else with a little electrical work added. Many beginners are utterly unfitted to become engineers, having neither the ability, perseverance, or genius. They may succeed in becoming threshing-machine engineers, but they would better save the time and money spent in trying to become what they were never intended to be. Engineering involves a long and thorough training: one must have a taste and a talent in that direction; must possess the ability to perform a great deal of hard, unromantic work for 24 or even 60 hours at a stretch, carry heavy responsibility, control men, and manage work; do the work of three men at once when necessary, and be 'up early and always at it.'" Probably one-half the budding electrical engineers of this nation would make much better citizens and do more good in the world if they were to pool their modest capitals into some good electric light or power stations, and then shovel coal or collect tickets.

The Secret of Good Management.—The good time for electric traction is said to be coming in this country, and therefore it is fitting to suggest beforehand that the managers of electric tramways will need to be constantly striking a balance between improved services and reduced cost of repairs and maintenance. On one particular line of some considerable length and importance says Mr. Shepardson, the latter item is now reduced to a minimum by careful management. The number of me at one time engaged merely in rewinding armatures wa no less than 65' a preposterous feature to an English engineer's mind. However, they are now less than 20 in number, owing to the employment of men who are mechanics first and electricians afterwards. The motor men in charge of the cars on the line are furnished each with a book giving clear explanations of the various parts of the car and its equipment, illustrating and explaining, so far as is desirable, the object of each part. They are taught how to take proper care of the motors, and how to make ordinary repairs in case of accident on the road. Specially trained inspectors are also out on the line at all times to examine motors which do not work properly, and if anything is out of order they repair it at once or send it to the shop before worse follows. It is found that these inspectors save their salaries many times over.

Gas v. Darkness.—Our contemporary the *Journal of Gas Lighting* is the *beau ideal* of a biassed paper. We have never yet found it modest enough to ascribe any possibilities to electricity, but it has determinedly, year in and year out, sought and promulgated whatever in its estimation seemed most damaging to electricity and most worthy of praise in gas. It is constantly pointing out the danger of being left in darkness where electricity is used, and makes much of every fact of the kind it can muster. Its misfortune is that having so long and so constantly cried "Wolf," few pay the slightest attention to its cry—and why? In the instance we have specified light or dark, every-

body knows that gas plays pranks, and occasionally leaves its users in darkness. The electrical papers would lose all indication of fairness were they to collect and comment upon every gas failure and gas accident. Our contemporary can make merry over electric light failures at Hastings; why not at the same time give prominence to the gas failure at Holywell! Surely, what is sauce for the goose is sauce for the gander. We acknowledge our antagonism to gas as a dirty, stinking, dangerous material, and think we are benefiting the human race by advocating the adoption of a better system of lighting, utilising gas if you like, where a little dirt and stink is less harmful, in heating and in engines.

Electric Interlocking of Railway Signals.—Illustrated particulars have just been published relative to the Ramsay-Weir electrical interlocking apparatus, and from the *Railroad Gazette* we obtain the following details of these appliances—in use now for several years. The interlocking is effected by means of electrical contacts controlled by electric magnets, the contacts in their turn being governed by the positions of the signals and switches. On each signal-post for operating the arm or semaphore is a steel box which contains all the working parts. The principal item is a small electric motor, whose elongated shaft carries a pair of centrifugal arms and balls of a similar type to those employed on the old-fashioned steam-engine governor. It is the centrifugal force of these balls, acting through a lever when the motor is running at 2,500 revolutions a minute, which serves to pull the signal arm to "clear," the normal position being "danger," at which point the arm is held by a counterweight. Similar arrangements are used for moving the switches or points, the motion being given by a double ratchet-wheel and pawl with spiral spring release. The electric energy required to operate the system is obtained from a dynamo at a pressure of 125 volts. A small gasoline engine and a storage battery complete the equipment. To charge the latter for 24 hours requires the operation of engine and dynamo for about eight hours, and the engine takes to do this work from eight to ten gallons of gasoline, costing, say, 4d. a gallon.

Lightning Expresses.—We have received a pamphlet from Mr. F. B. Behr, Assoc.Inst.C.E., entitled "Lightning Express Railway Service: 120 to 150 miles per hour," and containing a mass of details, with illustrations of the system, which the author considers is the only one capable of being safely employed for passenger transit of a more rapid kind than that now available on our steam-driven expresses averaging a bare 50 miles per hour. Of course, the author proposes to employ electric energy for operating the lines, and thereby adopts the most reasonable method, avoiding all reciprocating motions. The permanent way for such a rapid transit line cannot, in his estimation, safely be of the ordinary type, where two rails are laid upon sleepers resting upon the ground. He, therefore, confines his plans to the use of an elevated and built-up structure (like that of the Lartigue single-rail system), the rolling-stock being balanced, as it were, on each side of the structure, and running upon one rail at the top. This method avoids all possibility of derailment at the high speeds named, and brings the centre of gravity below the point of support. So far as can be seen from the details given, the type of electric motors proposed to actuate the train consists of an annular armature bolted to each side of the bearing-wheel (and therefore acting direct), which revolves between bi-polar field magnets on each side, secured to the framework of the car. At 600 revolutions per minute the horse-power of each motor is stated to be about 50. Motors are mounted on all the carriage axles, no locomotive being thereby used at all. The current collector is an arm fixed to the carriage, and projecting into a channel which contains a bare conductor wire. The latter is lifted up by the collector, thereby making contact by its own weight.

The Lighting of Swiss Villages.—The typical English village is usually not lighted at all—at the utmost it will only have perhaps a score of gas lamps, and the majority of its inhabitants go to bed soon after sunset, or else use candles of 16 or more to the pound. Switzerland is the happy possessor of innumerable waterfalls, and it uses them for lighting up the valleys, which might otherwise appear always dark and gloomy. A good example of this may be seen in the famous Gruyère valley, where cheeses grow by the roadside (according to Mark Twain's agricultural editor). Here there are four or five small places—not one probably with more than 3,000 inhabitants—which are supplied with electric energy for lighting and other purposes from a well-equipped station operated by water power. At Bulle, where there is an available fall of 100ft., and a sufficient quantity of water to give 200 h.p., a single horizontal turbine, made by Faesch and Piccard, of Geneva, drives two 75-kilowatt alternators, one on each side, with exciters mounted on the same spindle, and running at a speed of 420 revolutions per minute. The current is generated at a voltage of 3,000, 10 per cent. loss being allowed over the line; the alternations are 49 per second only. The overhead line—of bare copper—traverses a distance of nearly six miles from the station, branching then for five-eighths of a mile and 1½ miles respectively to the ends of the circuit. Transformers reduce the voltage to 120 for the consumers' circuits. A few motors of the Alioth type, with rotary field, are employed in the village of Bulle.

Voltaic Cells with Fused Electrolytes.—In instituting a comparison of the observed E.M.F.'s of cells with their theoretical values, as given in "Thomson's law," the simpler the construction of the cell, the easier it is to ascertain the nature of the chemical action on which the calculation rests. In cells with aqueous electrolytes, according to Mr. J. Brown, the solvent introduces several irreducible complications arising from possible action of the solvent itself as an electrolyte, from the formation of insoluble films (either inactive and protective, as oxides, or active as hydrogen), or from the uncertainty of calculations involving heats of solution of the products of voltaic reaction. When the liquidity of the electrolyte is produced by fusion instead of by dissolution, these complications are to a large extent avoided; and as a matter of experiment, two fluid cells made up of metals, immersed each in its fused chloride, gives results nearer the "theoretical" values than those obtained with aqueous solutions. This is specially noticeable in the case of metals with high heats of oxidation, as, for example, magnesium and aluminium. The E.M.F. of cells containing pairs of the metals tin, lead, and zinc come out nearest to the theoretical values. The other metals which were tried did not give so close an agreement, but could be brought into agreement by applying constant corrections, one for each metal; and reasons are given by Mr. Brown for attributing these corrections to the high temperatures of the cells, as compared with the temperatures for which the recognised heats of combination are true. Four of the cells were tested by passing currents through them in both directions alternately, and noting the E.M.F. after the passage of each current. Polarisation was observed in the case of zinc-silver, but in the others it was practically absent.

The Nutting Arc Lamp.—Of newly invented arc lamps, and mechanisms for them, there is indeed no end; every week the technical papers seem to unearth a fresh one—fresh, that is, so far as the name and minor details are concerned. Most have a strong family likeness to one another; and yet, in spite—or, perhaps, rather because—of the incessant competition, the old-established lamp-makers get nearly all the trade. None of them are perfect, however; though if only the good points of all could be combined in one we should expect to get a satisfactory lamp. An ingenious and perhaps genuine improvement is that which characterises the Nutting arc lamp; in this the feeding mechanism consists of a ring of waxlike material, 2½in. diameter, mounted between two ebonite discs on a shaft which is geared directly to the upper carbon rod. A metal pin is mounted on a stationary holder in such a manner as to have one end embedded in the surface of the wax to the extent of ⅛in. or $\frac{3}{16}$in., the cross-sectional area of the ring being about ½in. square. On the other end of the pin is wound a fine German-silver wire resistance equal to about 150 ohms; and this, together with an additional resistance of about 600 ohms, forms the shunt or feeding circuit of the lamp. When the pin is embedded in the wax, the upper carbon rod is held rigidly in place, but on the carbon points separating the shunt circuit will at once take its share of current, the proportion varying with the voltage of the terminals of the lamp, or the carbon points. The metal pin at once becomes heated by the passage of the current through the resistance wire wound upon it; and as it heats it warms and tends to melt the waxlike material in which its end is embedded, thus allowing the ring to slowly revolve and feed the carbon to the proper length. The hot wax at once solidifies behind the pin, leaving a smooth and even surface for the next revolution. Of course an adjustment is provided to allow for extreme change of temperature.

Scientific Papers.—Some discussion is taking place, principally among the members of the Physical Society, with reference to the publication of papers. The subdivision of societies, each with its own "journal of proceedings," issued to a strictly limited *clientele*, has made it difficult for workers to keep in touch with their work, and there is no doubt, says the *Pall Mall Gazette*, that a vast amount of valuable time is being wasted in doing and re-doing work which has already been done, and the details of which are accessible in print if only there existed some suitable system of reference. The want of such a system is growing more and more pronounced, and various solutions of the difficulty have been proposed. One is the formation of a national bureau, in which all current technical literature should be classified and indexed under the different branches of science. Another is that the method of publication should be revised. Mr. A. P. Trotter suggests that the method of publication adopted by the Physical Society is the most free from objection, and that for physics papers the society might well be made a basis of centralisation. The more elaborate and important papers would still go, as they do now, to the Royal Society, whose *Proceedings* are, however, costly, and not very widely read; mathematical papers could appear in the *Philosophical Magazine*, which at present, by arrangement, publishes most of the Physical Society's papers in duplicate; and the physics papers, pure and simple, which represent the work carried on from day to day by the leading professors and experimenters, could be dealt with by the society all the year round. Most people, observes our contemporary, are agreed that some arrangement will shortly have to be made whereby rivalry among the older and younger societies will be avoided and a wider circulation obtained. In America, where the same difficulty has been found to exist, a move has been made in the direction of centralisation. Mr. J. F. James describes the foundation of an institution called the Scientific Alliance of New York, the chief object of which is the establishment of a centre where knowledge of what is done in one society is conveyed to all the rest. The Alliance is not a year old yet, but is already in a fair way of doing good work.

The Government and Telephony.—The telephone question is becoming rather acute. So far, nothing that has been said has induced the Postmaster-General to divulge the terms of the agreement that will shortly be signed with the National Telephone Company. Replying to Captain M'Calmont on Monday, Mr. Arnold Morley said the Postal Department had determined to make it a condition of any new telephone licenses that the system should be constructed entirely of twin circuits, so that there might be an assurance of efficiency, as the present system of a single wire with an earth return was at present causing great dissatisfaction in some large cities. Questioned by Mr. A. O'Connor as to whether the policy of the Department was that no new licenses would be granted unless with the consent of corporations and municipal authorities, the Postmaster-General referred to the Treasury minute laid before the House of Commons on May 27, 1892, as follows: "For a license to establish an exchange in a particular town no application will be entertained unless a formal resolution in its favour has been passed by the corporation or other municipal authority, and evidence given that there is sufficient capital subscribed to carry out the undertaking." In one case a resolution of this kind qualified by conditions had been conveyed to him by the applicant for a license. The telephone companies possessed no statutory powers. Application for a license had been made by the Corporation of Glasgow. Replying to Mr. Henniker Heaton and Mr. Cayzer, Mr. Morley explained that it was not proposed to confer a new license on the National Telephone Company; the date for the termination of their license was December 31, 1911, and that date would remain undisturbed. So also would the freedom they at present exercised in fixing their charges for telephone exchange wires. The main object of the new agreement was the purchase of the trunk lines and the consequent withdrawal of the right of the company to erect and work such lines. As to the submission of the agreement to Parliament, he referred to previous answers that the agreement would be placed before them when completed (answers on July 31 and the 18th and 31st ult.). It is stated that the question of municipal telephones will again be raised in Parliament, and a statement on the subject has been circulated amongst members of the House of Commons. With regard to the same question, Captain Bagot, M.P., intends to ask the Postmaster-General to-day, "Whether, in view of the fact that the report of the Select Committee on the Telegraphs Bill, on which the agreement between the Post Office and the National Telephone Company is to be founded, was arrived at without any evidence being taken either from any municipal corporation or from any representative of the telephone-using public, he will consider the advisability of reappointing a select committee to take further evidence, in the interests of the public or the corporations, on the subject, before concluding the agreement with the National Telephone Company." We give in another column a copy of the circular issued by the Glasgow Corporation on the telephone question, and as the subject is of such immediate interest we have no hesitation in reproducing from the *Times* of yesterday the article printed on another page.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC.MEM.INST. ELECTRICAL ENGINEERS.

(Continued from page 175.)

DISTRIBUTION OF ELECTRIC POWER.

The word "system" used in connection with the generation and distribution of electric power, is as much misused as that other unfortunate word, "accumulator." A "secondary battery" no more accumulates electricity than a machine gives out more energy than is put into it. The electric energy put into it simply produces certain chemical reactions, and so the electric energy is converted into chemical energy, which latter can be reconverted back into electric energy again when wanted by allowing the plates to regain their original chemical condition. But there is no "accumulation" going on; in fact, it is rather the reverse, seeing that there is a dead loss of above 25 per cent of the electric energy put into the cells. When the electric light was first exploited, in the days of the mania of 1882, everything electrical was somebody's "system," every arc lamp or dynamo put upon the market was called some system or other of electric lighting, and since the bulk of them were dismal failures, the word got bad repute. No particular piece of apparatus constitutes a system, whether patented or not. Furthermore, the dynamo was only invented once, crude, at first, certainly, but gradually improved first in one way, then in another. Then various well-defined types were evolved, as drum, disc, and ring armatures, horseshoe, double horseshoe, and multipolar field magnets, series, shunt, and compound winding. By merely collecting the current we obtained alternating currents of electricity; afterwards, inventive minds added the commutator, and this gave us continuous currents of electricity. Finally, coming close to the present time, two or more pairs of separate collecting rings were keyed on the shaft, each pair being connected to so many of the armature bars, and thus we obtained two, three, or multiphase alternating currents. Again, the question of pressure was determined by the thickness and number of armature wires or bars – armatures wound with a great number of thin wires giving high pressure currents, say at 1,000 volts, those wound with a few thick turns giving low-pressure currents, say at 100 volts. Dynamos are not invented nowadays: like steam-engines they are designed, each dynamo builder having his own ideas of details of construction, the data for the same having been collected by experience and actual experimental tests, obtained at a great cost of time and money, in many cases a score of differently-designed parts being tried and condemned before the right one is found.

Broadly speaking, there are two chief and entirely distinct methods of supplying and distributing electric power, and which may with truth be called "Systems." These are (1) the Low Pressure Continuous-Current System, and (2) the High-Pressure Alternating-Current System.

Low-Pressure System.— We will deal with this system first, as it is of less importance than the other. Low-pressure currents can only be used to distribute electric power over very limited areas, the reason being that when electricity is distributed at a certain pressure from some central source there always must be a gradual fall of pressure through the distributing mains, and this fall of pressure becomes greater and greater as the distance from the source increases. A system of water service affords an exact analogy, as the pressure of the water becomes less the farther it travels from its supply source. From this it is evident that the fall of pressure will have a serious effect on the lamps. In the last article but one, it was shown in Tabulation 24 that a slight fall of pressure of only 4 per cent. causes an enormous loss of light, as much as 25 per cent., so that while the lamps that are close by the source of generation burn brightly, and at their normal candle-power, the lamps will burn dimmer and dimmer as their position becomes farther away from this source. A fall of pressure being therefore inevitable, the best thing to do is to try to reduce this fall as much as possible. By Ohm's law we know that the fall of pressure along a wire is represented by the number of volts necessary to force a certain current through a certain resistance in ohms. Five hundred amperes flowing through a main cable 500 yards long and 1in. diameter, and having a resistance of ·16 ohm, will signify a fall of pressure at the farther end of ·16 × 500 = 8 volts. The current density here being about 636 amperes per square inch, but this is only for one cable. The return cable must also be reckoned. This gives us a total drop of 16 volts, which is absorbed in sending the current through the cable—eight in the positive cable, and eight in the negative; so that if the working pressure at the source be 100 volts, and a lamp be fixed 500 yards away, connected to the end of this cable, it will only receive 74 volts at its terminals, and naturally will be useless for illuminating purpose. This example will give an idea how great is the loss of pressure when heavy currents have to be carried any considerable distance.

There are several methods in use by which the low-pressure system is enabled to supply larger and more extended areas, such as by the adoption of what are called "feeders," the three-wire system, the five-wire system, etc., all these being added to the simple parallel system. The simple parallel system consists, as its name implies, of a pair of mains or a number of pairs, radiating out in various directions from the generating source, the sub-mains and branch wires being tapped off along the route; and since incandescent lamps only take a pressure of 110 volts at the most, therefore the pressure at the generating station must be that, or, say, two or three volts more, in order to allow for the drop of pressure along the mains. Suppose the station pressure is 112 volts when the full load is on, and that there is a total fall of four volts between the station and the farthest lamp burning; now, when the load lightens and becomes, say, one-half of the full load, this fall of pressure will be only two volts, because the current density in the distributing mains is only one-half of what it was before, and hence the pressure required at the station will now be 111 volts. This variation of pressure can easily be obtained by a rheostat in the field of the dynamo, or else by varying the speed of the engine. A simple parallel system like this is of very little use in distributing electrical power from central stations, because the area it would supply would be too limited in extent; at the outside, it could only be used for a radius of 200 yards. This distance is no more than would be suitable for a large manufactory or block of houses where a private plant is put down. The distance that a certain current can be carried for a fixed percentage of fall of pressure depends on the current density employed in the mains; when the density is high the distance is short, and when low the distance is long. The resistance of the mains is constant in value whatever the current may be, so that as the current increases in the main it requires more pressure to force it through this resistance. We arrive, then, at this rule:

Distance is inversely ∝ current density.

This applies when the pressure at the source is constant in value, as it would be in any parallel system of distribution. The following distances in yards have been calculated out to show various percentages of fall of pressure for various current densities per square inch sectional area of copper main.

TABULATION 28. – Percentage of Fall in Pressure.

Current density.	½ %	1 %	1½ %	2 %	2½ %	3 %	3½ %	4 %
300	33	66	100	133	166	200	233	266
400	25	50	75	100	125	150	175	200
500	20	40	60	80	100	120	140	160
600	[illegible]	33	50	66	83	100	116	133
700	15	30	43	57	70	85	100	114
800	12	25	37	50	62	75	87	100
900	11	22	33	44	55	66	78	89
1,000	10	20	30	40	50	60	70	80
1,100	9	18	27	36	45	54	63	72
1,200	7	15	22	30	37	45	58	66

The range of fall of pressure is from 1 to 4 per cent. The distance in yards signifies the actual distance of the lamp from the source of generation, and hence the fall of pressure is along a length of cable equal to twice this distance, because the length of both positive and negative cable must

be taken into account. Taking the greatest distance shown—namely, that of 266 yards—there is here a fall of 4 per cent., so that if 100 volts were given at the dynamo, only 96 would be received by the farthest lamp, fixed 266 yards away, and this is with an extremely low current density of 300 amperes per square inch. To employ such a low density would mean that an enormous weight of copper would be sunk in mains and branch mains, and the expense of this mass of copper would be extremely great. To attempt to carry these mains any farther away would make the fall of pressure so much that the lighting would be perfectly worthless, because if the fall of pressure was doubled, and made 8 per cent., it would only give a working radius of 532 yards, and so it is clear that it is practically impossible to distribute power over any wide areas, like a town of five or six square miles, by using a simple parallel low-pressure current of only 100 or so volts.

(To be continued.)

PATIN FLYWHEEL ALTERNATOR.

(Concluded from page 209.)

As complement to the flywheel alternator, M. Patin has constructed a type of transformer very noticeable for its high efficiency and its low absorption of current at no load

This transformer is of the closed magnetic circuit type. It is of the form of a rectangular parallelopiped, Figs. 10 and 11. The coils of the secondary circuit are placed upon

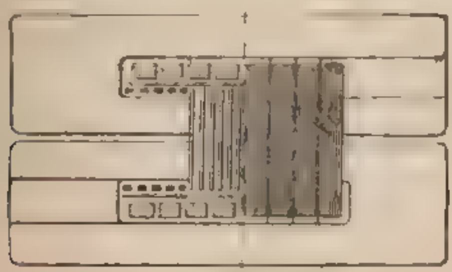

Fig. 10.—Patin Transformer.

the iron; the primary circuit is composed of eight coils in the form of tubes of rectangular section: these are insulated from each other in addition to the insulation of each turn of wire. The magnetic circuit is also constituted by two kinds of tubes of rectangular section, placed parallel to

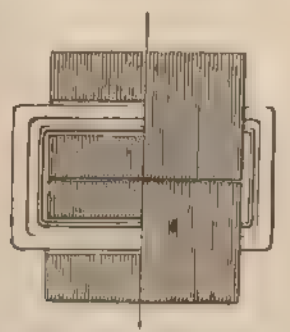

Fig. 11.—Patin Transformer.

each other on their largest side. Each of these is composed of soft Swedish iron plates, carefully laminated and cut to measure, and covered with paper on one side. These iron sheets are stamped in the form of the letter U with right angles, so as to give the least possible amount of waste pieces. These latter, moreover, are utilised in the construction of the small transformers which are used for test lamps in the central stations.

The iron sheets are arranged in pairs, with their metallic sides touching. A sufficient number are laid together, and the edges are then slightly rounded. This system, allowing easy putting together or repair, gives a very low magnetic resistance.

The sheets are compressed between two cast-iron frame plates bolted securely together, each having two cavities, in which are placed two porcelain bases, which carry the gunmetal terminals of the primary and secondary circuits.

The efficiency at full load is very high, and is hardly ever less than 98 per cent.; the absorption at no load is extremely low, and barely reaches 2 per cent. The following table gives the figures of two Patin transformers of 4,000, Fig. 12, and 8,000 watts, Fig. 13, respectively.

Capacity of transformer.	4,000 watts.		8,000 watts.	
	Primary	Secondary	Primary	Secondary
Voltage ...	2,400	100	2,400	100
Turns of wire	1 080	45	720	30
Size of wire	16 10	3 × 43/10*	20 10	6 × 40/10*
Length of wire	880m	29 5m.	—	—
Thickness of iron sheets	5/10		5/10	
Section of iron ...	180cm.^{2}		—	
Loss	12 volt	0 5 volt	12 volt	0 5 volt
Efficiency ...	96 per cent.		66 per cent.	

* In parallel.

The frequencies may be varied between 50 to 83.

We may conclude this description of the Patin system with the following results obtained with the flywheel alternators in two installations of very different size, driven by different types of engines.

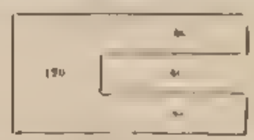

Fig. 12.—Sheet for 4,000-watt Transformer.

The first was driven by a turbine furnished with a Faesch and Piccard regulator; and the second by horizontal steam-engine with variable cut-out of the Blondel system (illustrated last week); the variation of voltage when the load is thrown suddenly off is less than 2 per cent.

Capacity in watts	40,000	120,000
Volts at terminals	2,400	2,400
Current at full load—amperes	16·7	50
Resistance of armature—ohms	4·5	0 96
Number of field coils	24	104
Resistance of fields—ohms ...	4·8	2·5
Number of armature coils.. ...	24	104
Revolutions per minute	300	95
Frequency	60	82
Efficiency	94	96
Exciting energy—watts	1,200	2,400

The expenditure of watts for excitation of field is included in the calculation of efficiency.

The Patin flywheel alternator, of which an illustration has been given, now at work in the workshops of M. E. Boyer, is of considerably higher capacity than the Blondel engine used to drive it, so that the efficiency given is less than it should be if engine and dynamo were of the same power.

Fig. 13.—Sheet for 8,000-watt Transformer.

The engine has a piston 0·360 metre diameter, 0·700 in stroke, speed 80 revolutions per minute. According to indicator diagrams taken, the engine running light absorbs 6·2 h.p. (the provisional installation does not include condensers). The engine will supply 280 16-c.p. lamps, indicating 30·3 h.p., and 380 lamps 16 c.p., for 38·6 h.p., or about 12 lamps of 16 c.p. per indicated horse-power.

The efficiency of the engine is 87 per cent., of the dynamo 94·2 per cent. The illumination is steady and brilliant whatever number of lamps are lighted.

It may be added to the above description of his dynamo that M. Patin is now carrying out tests with a dynamo for transmitting power by alternating currents, and that very important results in this direction have been already obtained.

WORLD'S FAIR ELECTRICAL PLANT.*

BY R. H. PIERCE.

(Concluded from page 210.)

Distribution of Arc Lighting.—Having indicated the general arrangement in Table A, I will describe as briefly as possible the plant, taking up the different kinds of service in order. For the purpose of description, we will divide all the dynamo-electric machines into two classes. First, exposition dynamos, or machines furnishing service to the exposition and operated by the electrical engineering department; secondly, exhibit dynamos, or machines furnishing current to exhibitors in Electricity Building and operated by the various electrical companies which furnish them as exhibits. The arc light plant comprises the following machines:

	Dynamos.	Lights each.	Total lights.
Western Electric plant	10 exposition	50	500
	2 exhibit	50	100
Thomson Houston plant	27 exposition	50	1,350
Excelsior plant	6 exposition	50	300
Standard plant	22 exposition	50	1,100
Fort Wayne plant	13 exposition	60	780
	1 exhibit	60	140
	1 "	80	
Brush plant	12 exposition	60	720
	4 exhibit	60	240

having an insulation of ⅛in. Para rubber compound, a part having mechanical protection of lead, and the remainder being protected by two tapes wound in reverse. Ninety miles of this wire is used. The circuits in the main subway and in buildings are of No. 8 B.W.G. safety wire, having a covering of 74 mils thickness of rubber and braided. Of this wire there are about 200 miles.

All arc lamps are furnished with opalescent or opal globes. This, of course, materially reduces the candle-power, but by diffusing the light undoubtedly gives much more uniform and satisfactory lighting than could be obtained by clear or ground globes. The general style of construction in the buildings consists in suspending the lamps from a No. 9 W. & M. iron wire, the conductors being run from lamp to lamp in the air. The lamps are attached to hangers which are insulated both from the lamps and the line. This method of construction has the advantage of using the minimum amount of wire and doing away with all unsightly loops. It is quickly and cheaply put up and presents a neat mechanical appearance. The lamps on posts and over the aisles in buildings are trimmed with step ladders, except in Machinery Hall, where they are trimmed from travelling cranes. In certain cases where the lamps are hung in inaccessible places, a special form of hanger is used, so that by pulling a cord the lamp can be disconnected from the circuit and dropped to any desired height, and again pulled into place, without interrupting the circuit. The device also does away with the use of any slack wire.

There are therefore 90 exposition dynamos, having a total capacity of 4,750 lights, and seven exhibit dynamos, having a total capacity of 480 lights, or a grand total of 99 dynamos, having a total capacity of producing 5,230 lights, all of 2,000 nominal candle-power. All these dynamos are regular direct-current series machines, and are equipped with standard switchboards and appliances of the respective systems.

In addition to the foregoing, there are in the terminal station 160 six-ampere arc lamps, and 228 three-ampere lamps, equivalent to 164 lamps of 2,000 nominal candle-power. There are also 351 Helios arc lamps attached to the incandescent circuits, most of these furnishing lights to exhibitors and to the concessionaires in the Midway Plaisance. The grounds are lighted by 1,421 lamps, of which 1,308 are upon ornamental iron lampposts, and the remainder, which light the fences and the south grounds, upon 40ft. wooden poles.

The grand total of all arc lamps in the plant at the present time is equivalent to 5,362 lamps of 2,000 nominal candle power. The outside circuits are all carried underground, excepting those south of Machinery Hall and along the fences. In the duct trunk line and in all underground ducts, the conductors are of No. 8 B.W.G. rubber covered safety wire,

The grounds and all the buildings are supplied with two entirely independent circuits. One set of evening circuits has single-carbon lamps, calculated to burn from dark to the closing hours of the night. The other set of circuits, which comprise about 10 per cent. of all the lighting on the grounds, is used for patrol, or all-night lighting.

The feature of the arc lighting is undoubtedly the lighting of the central nave of Manufactures Building. Here the lights are suspended from five great fixtures or coronas. The space to be lighted is 1,268ft. long and 368ft. wide. The coronas are suspended 140ft. from the floor. The central corona is 75ft. in diameter and carries 102 lamps. The other four coronas, which are equally distributed along the main longitudinal axis of the building, are 60ft. in diameter and carry 78 lights each, making a total of 414 lamps. The coronas, which are made of angle iron, are circular hanging galleries in which the trimmer can walk from lamp to lamp. They are reached by iron ladders from the trusses above. The great arched roof of the building acts as a reflector for the lamps, and the lighting, as it appears to the eye, is absolutely uniform.

Search lights. — There are at present installed four Schuckert search-lights on the four corners of the Manufactures Building. These lamps are operated from the 180 kilowatt 120-volt Siemens dynamo in the British section in Machinery Hall. Two lamps are of 150 amperes, one of 100 amperes, and one of 60 amperes. The diameters are respectively 60in. 44in., 36in., and 24in. The 60in. lamp on the north-west corner is the largest and most powerful ever built, and gives a beam having an intensity of 194,000,000 c.p.

Incandescent Plant.—All but a small portion of the incandescent lighting of the exposition is supplied from the Westinghouse plant. This plant comprises 12 10,000 light dynamos, six of which are directly connected to 1,000 h.p. engines and six are belt driven, and two 4,000 light dynamos, also belt driven. All these dynamos furnish a current of 2,200 volts E.M.F., and are compound wound. Each 4,000 light machine has its own exciter, but the 12 10,000 lighters have their fields excited by three 100-h p. exciters, which are operated in multiple arc. These machines are all connected to an immense switchboard, which is the most striking object in the electrical plant. This switchboard, which is of white marble, is arranged in two storeys or sections. The lower, or dynamo-board, controls all the dynamos. Each large alternator is a double machine having two independent armatures, so that the board practically has connections for 26 alternators and five exciters. The three large exciters, which are compound wound for 250 volts, are connected to a three-bar 'bus system, which feeds the fields of all the large dynamos. The second storey of the board is the circuit-board, carrying instruments and switches for 40 circuits or feeders, and the whole system is so arranged that any dynamo can be connected to supply current to any of the 40 feeders. The 12 large machines are wound for only 7,200 alternations per minute, thus supplying current which can be used with perfect success in supplying arc lights. Each large machine, as before stated, has two independent armatures. These armatures are so connected that the two circuits from each dynamo carry current differing in phase by 90deg., so that any of the large machines may be used to furnish current for operating either incandescent or arc lamps, or two-phase motors. The distribution of incandescent lighting is shown in the following table :

The circuits or feeders are calculated for a loss not to exceed 10 per cent., each circuit being provided with a Stillwell regulator capable of increasing or decreasing the initial pressure on a circuit 5 per cent. All circuits, excepting one to the south grounds, are run entirely under ground The cables, from the switchboard to converters, are all duplex Waring cables, except in the main subway, where Grimshaw rubber-covered wire is run on insulators. All converters are placed in fire and waterproof pits just outside the buildings, and the secondary wires are led into the buildings in vitrified tile duct. The largest converter used has a capacity of 200 lights, and nearly all are of that size. Every converter on the ground has its own independent secondary circuit, so that no trouble upon a secondary or inside circuit could ever put out more than 200 lights. The secondary wiring is controlled in all cases by switches and cut-outs located at points where wires enter the buildings, and the circuits are, in general, distributed from asbestos-lined boxes in which the cut-outs and switches are bunched at centres of distribution. The inside wiring is done entirely with the best grade of Grimshaw rubber-covered and taped wire, and the wires are run almost entirely in standard moulding or in interior conduit. The lamps, which are of 105 volts, are all the new stopper lamp of the Westinghouse Company. The general standard of the exposition lighting for lamps suspended at the ordinary height from the floor is 40 square feet of floor surface per 16-c.p. lamp, but inasmuch as the plant presents almost every variety of an incandescent lighting problem that can be thought of, the intensity of lighting varies greatly, ranging from 18½ square feet per 16-c.p. lamp in the Gallery of Fine Arts, and 7½ square feet per 16-c.p. lamp in the smallest gallery, to 3,700 square feet per 16-c.p. lamp for the system of patrol lighting under the floor of the Manufactures Building. The most novel lighting is the lighting of the tanks in the Fisheries Building, the aquaria being lighted only by invisible lights shining through the water of the tank. The most brilliant lighting is the lighting of the Gallery of Fine Arts, where the lamps are placed in reflecting screens around all sides of each picture gallery, the lights being only 8in. from socket to socket for nearly two miles of screens. The finest lighting is undoubtedly that of the Administration Building. The lighting of the interior is wonderfully uniform, and, in conjunction with the exterior decorative lighting, forms probably the most difficult and beautiful piece of incandescent lighting ever executed. In the incandescent lighting of the exposition it has been the aim throughout to avoid display lighting, but to secure sufficient and uniform illumination, and, where the lights have been placed for decorative effects, to place them so as to be inconspicuous by day, and to bring out at night the decoration or lines of the buildings. Wall sockets have been largely used, and stiff pendant fixtures have been used, but in one building simple clusters hung from flexible cord being almost universally used. This method of construction proves very satisfactory, and has the advantage of being easily and quickly installed, so as to always present a mechanical appearance. It is easily maintained, and, what is important in an exposition, the position of the lights can be easily and quickly changed without disfiguring or damaging the ceiling.

In addition to this lighting, the Siemens and Halske Company, of Berlin, has installed the following incandescent lights : Wooded Island, 120, 25 c.p. ; Choral Hall, 1,740 lights, equivalent to 2,462 lamps of 16 c.p. ; terminal station, 567 lamps, 16 c.p., being equivalent in all to 3,117 lamps of 16 c p. This makes a total of all incandescent lamps of equivalent of 68,789 lamps of 16 c.p. The Siemens and Halske lights are operated from a generator in the German section, Machinery Hall, having a capacity of 700 kilowatts, and furnishing current to the light mains of 440 volts. The lamps upon Wooded Island are operated in series of four, and incandescent lamps in the buildings are operated upon a five-wire system with equalising motors at the centres of distribution. The feeders are of armoured cable laid direct in the ground. This plant is interesting as illustrating the difference between European and American practices, and is the only plant of its kind in practical operation in this country.

Power.—Although the electric lighting has been carried out on a scale never before approached in an exposition, it is in the transmission of power that the advance of the art of electricity is most conspicuously shown. With the exception of the power in Machinery Hall, and a portion of the power in the Mines and Mining Building, all the power which is transmitted from the great power plant is transmitted by electricity, and even in Machinery Hall al

operates the great cranes, the elevators, and a part of the main-line shafting. Circuits are so arranged that power can be had in any building and in any portion of the grounds. The generating plant in Machinery Hall comprises the machines shown in the following table:

GENERATORS.

	Make.	No. of gen.	KW.	Voltage	Total KW.	
Exposition:	Mather	2	225	550	450	
	Mather	2	120	550	240	
	"C. & C."	4	80	550	320	
	"C. & C."	2	80	250	160	
	Eddy	4	186½	550	746	
	Westinghouse	1	373	550	373	
						2,289 kilowatts.
Exhibitors:	National	1	80	500	80	
	Jenney	1	40	500	40	
	Western Electric	2	137½	250	275	
	Wood	1	120	500	120	
						515 kilowatts.
	Grand total					2,804 kilowatts.

Making a total generating capacity of 2,289 kilowatts, or 3,070 e.h.p., for exposition use, and 515 kilowatts, or 690 e.h.p., for exhibitors' use—a grand total generating capacity of 2,804 kilowatts, or 3,585 e.h.p. All the generators, except two 80-kilowatt machines, which supply the power for the elevators in Administration Building, are regular street railway generators, wound for 500 volts, with a guaranteed E.M.F. of 550 volts at full load. Each type of machine has its own independent switchboard, but relay circuits are run between boards, so that in case of emergency the feeders from one board can be fed from the generators of another. The circuits are run in the main subway and upon the structure of the elevated railway. The feeders and mains consume 180,000ft. of No. 0000 wire, B. & S. gauge, 19,000ft. No. 000 B. & S. wire, 12,000ft. No. 0 B. & S. gauge, and 24,000ft. No. 1 B. & S. wire. This is exclusive of the distributing mains running to the various motors. All the wire is rubber covered and braided, the No. 1 wire having $\frac{3}{32}$in. thickness of rubber, and the larger sizes are covered with ⅛in. thickness of rubber. The cable is of the make known as the E. M. W. The motors used by the Exposition Company are all supplied by the General Electric Company, with the exception of two 150 h.p. Westinghouse motors operating shafting in the Mines and Mining Building. Exhibitors provide their own motors of such type as they wish. The applications of electric power are almost universal, as electric motors are used to operate almost every kind of machine in use by the exposition, or displayed by exhibitors. The distribution of light and power as shown in the tables is exclusive of the electric power consumed in the Electricity Building. This building consumes all the electricity generated by the machines designated as exhibit machines, the electricity being used for light, heat, and power, and for producing the many electrical effects displayed in the Electricity Building.

Electric Launches and Electric Fountains.—The four 150-kilowatt Edison dynamos furnish current for operating the electric fountains in the evening, and for charging the storage batteries of the electric launches after 10 o'clock at night. Each fountain is illuminated with 19 80-ampere Knowles arc lamps, requiring in all 300 kilowatts, or 400 e.h.p. The launches, 58 in all, are each equipped with a motor of 4 h.p., operated by a storage battery of 78 cells. The circuits of both fountains and launches are of Edison underground tubing, and are arranged as a three-wire system.

Intramural Railway.—Although it is not a part of the plant in Machinery Hall, a description of the electric plant would not be complete without a reference to the electric intramural railway. This road is the finest elevated electric railway ever constructed. The station has a generating capacity of 3,700 kilowatts, or 5,000 e.h.p., including the largest railway generator in the world, rated at 1,500 kilowatts, or 2,000 e.h.p. The road has 6¼ miles of single track, and is installed with a third rail system. The cars are regularly run in trains of four, each having a capacity of 133 h.p., with a speed of 25 miles an hour.

Installation Rules and Inspection.—The installation of the electrical plant throughout has been carried out according to the rules known as the national code, which was accepted as the standard by the insurance auxiliary committee. This code has been made part and parcel of all specifications and contracts. More than ordinary care has been exercised in inspection. Each large building has had a special inspector, as well as each principal branch of the work. Working plans were made showing the location of every lamp, either arc or incandescent, except where lights were located in exhibitors' spaces or pavilions of which detailed plans could not be obtained, and in these cases the plans show circuits up to the cut-outs in exhibitors' spaces. The contractors for incandescent lighting were required to submit for approval, in all cases, working plans showing details of cut-out boxes, and arrangement of circuits, showing each light, and having marked in figures the length of each circuit and the gauge of the wire. Four prints were made of each plan, the contractor and exposition each keeping one print as a record, the third print being given to the foreman of the contractor as a working plan, and the fourth being given to the Exposition Company's inspector, whose duty it was to see that the work was installed according to the plan and national code, and in a workmanlike manner. Although the making of complete wiring plans has apparently never been considered necessary by architects, it was found to be the only way in which a work of this magnitude and variety could be thoroughly inspected, and the results obtained were most satisfactory. The inside wiring almost always tested out perfectly clear, with very high insulation, and when the lights were thrown out by thousands for the first time, the inside wiring was almost absolutely free from "bugs," and if there were any they were so easily removed that their presence was never noticed.

Much that would be of interest cannot yet be written, for the efficiency of the various machines is yet to be determined by tests, and the length of this paper does not admit of going into details of construction; but I will conclude by enumerating a few points to which I would especially direct the attention of such as may wish to draw conclusions from the inspection of the electric plant.

1. The great saving of space to be made by the use of the direct-coupled dynamo.
2. The advantage of the adoption of a central-station system having machines of one type, and large units suitable for supplying both arc and incandescent lights and power service from the same conductors.
3. The advantages in series arc wiring of construction and devices which do away with slack wire, and admit of more mechanical construction and a neater appearance than is generally obtained in this class of work.
4. The possibility of, in all cases, doing mechanical work and at the same time having all conductors accessible.
5. Advantages to be gained by the use of iron pipes as an interior conduit, not only as a matter of safety, but economy.
6. The advantages of an inspection of electrical work, not merely by making electrical measurement after the work is completed, but by having practical men see that the work is mechanically perfect as the work is being done.
7. The great advantage of having complete detailed working plans of wiring construction, in order to be sure that the work is properly laid out, and is installed as it is laid out; and in order that the work may be at any time easily maintained and readily changed or repaired by any intelligent workman.

Electricity for Canal Boats.—It is stated that experiments on a tolerably large scale are now being made on the Erie Canal with a view to seeing how far the electric trolley may be applied to the propulsion of vessels. The Westinghouse people are erecting a line over the section from Rochester to Westport, New York, whilst the General Electric Company are responsible for a length of three miles west of Albany, New York, on which the experiments are carried on. A maximum speed of five miles per hour is aimed at.

A NEW INCANDESCENT ARC LIGHT.*

BY L. B. MARKS, M.E.

Electrical literature is replete with studies of the incandescent lamp as a source of artificial illumination; the performances of arc lights under a great variety of conditions have also been published from time to time; but the subject of the so-called incandescent arc, singularly, has received little or no attention.

In view of this fact, it has seemed desirable to report at once on a series of investigations which, though still incomplete, have disclosed some remarkably interesting and important phenomena with reference to a new form of incandescent arc light. The experiments have been carried on far enough to demonstrate that this source of illumination is *sui generis* While possessing the main characteristics of the ordinary arc, it is also akin to the incandescent light, and may be said to constitute a mean between these two.

The Typical Incandescent Arc.—The incandescent arc has been described as one in which the "two electrodes are in imperfect contact," the current thereby meeting with a high resistance and producing heat effects, which manifest themselves in the incandescence of one electrode and the formation of a number of very small arcs between the uneven parts of the electrodes in contact.

On this principle, Reynier, Werdermann, Joel, Tommasi, and others constructed lamps years ago, but for well-known reasons none of these "semi-incandescent" lamps, as they were called, found much practical application. The Sun lamp of Clerc and Bureau was a modification of the others, the arc impinging on the surface of a block of marble or condensed magnesia between the tips of the electrodes. In this form there was a rapid waste of the non-conducting substance interposed, and a diminution in the efficiency of the light.

The New Incandescent Arc.—The incandescent arc to be treated of in this paper differs radically from any of the forms alluded to above. In it, the electrodes are not in contact, while the current is indirectly used in maintaining all the products of disintegration of the carbon in a state of incandescence or opalescence.

The arc is enclosed in a small envelope, which is made of highly refractory glass. The envelope is closed at the bottom and provided on top with a metal plug having an opening in it just large enough to admit of the feed of the upper electrode. A fireproof plug of asbestos pulp insulates the metal from the glass. A valve in the plate allows the egress of gas, but prevents ingress of the air. With this construction the operation of the lamp will be as follows: Upon the closure of the circuit, and the springing of the arc, the air in the enclosing envelope is robbed of its oxygen, the latter uniting with the carbon of the electrodes to form CO and CO_2 gases. The gases are brought to an exceedingly high temperature, at which they maintain the carbon vapour issuing from the arc. This vapour is deposited in the form of a thin coating on the internal surface of the glass chamber. The expansive force of the gases may become sufficiently great, if no means of egress be provided, to rupture the envelope; hence, a small safety valve is provided for their outflow. The only possibility of ingress of air is through the narrow space between the positive carbon and the plug; experience has shown that after the temperature has been raised beyond a certain point the amount of air that enters in this way is inappreciable: in any event, the oxygen is immediately converted by combination.

It is important that the enclosing glass envelope be as small as possible, for the conservation of the radiant energy, and hence the efficiency, will depend largely upon the size of the chamber. The heat which in the ordinary arc light is dissipated in the air is here conserved, and raises the temperature of the enclosed gases and vapour of carbon. The proper conditions being fulfilled, the lamp maintains its maximum efficiency shortly after the current has been passed through it, and glows like the incandescent with the brilliancy of the arc light. The arc proper is scarcely visible, but the entire contents of the chamber seem to be luminous, giving the appearance of a solid cylinder of light.

* Abstract of a paper read at the International Electrical Congress, Chicago

The pressure, as well as the temperature of the enclosed gases, has a very important bearing on the performance of the lamp, and affects to a marked degree the character of the carbon deposit on the glass chamber. At this date no definite figures can be given, but it appears that a high tension is absolutely required to give good results. The structure and constituency of the electrode are also pre-eminently important. Absolute purity of the carbons is imperative. Investigators in this field have apparently found it impossible to obtain all the requisite conditions. Beardslee mentions a type of lamp similar to the one under discussion, but whether the size or character of the arc-enclosing chamber, the nature or management of the gases, or the quality of the electrodes, or other features made his arrangement impracticable, is not recorded. Suffice it to say, the comparatively poor grade of arc light carbon manufactured 10 years ago would alone explain his failure.

It is interesting to note here that attempts have been made at various times to save carbons in arcs by excluding the oxygen of the air. Baxter devised several forms of arc lamp with this object in view. The subject has been more recently referred to by Thompson. These experiments were attended with little practical success, not because the desired ends were infeasible, but probably because, as in the case of Beardslee's apparatus, alluded to above, one or more of the requisite conditions had not been attained. It appears that the saving in life was more than counterbalanced by the loss in light. The "incandescent effect" was absent, and the unsteadiness of the arc itself was fatal. The results were almost identical with those obtained when the arc is formed *in vacuo*. In this case there is a tendency of the carbon to deposit as a soot on the sides of the vacuum chamber, an effect consequent upon the vapourised carbon in the arc being carried off and condensed again as soon as the vapour escapes the heat of the arc stream.

But the requisite conditions hereinbefore named being once attained, the arc is really a beautiful phenomenon. It differs in many respects from the arc in open air, being especially steadier than the latter. The light emanating from the incandescent vapour of carbon appears to issue from all parts of the small enclosing envelope, the area of the source of illumination being limited only by the size of the chamber.

Efficiency Measurements.—Measurements of the efficiency and candle-power of the light were made in the laboratory of Cornell University. The method employed in making the efficiency tests was that used by Nakano in determining the efficiency of the arc lamp, and subsequently by the writer in an investigation on arc light carbons. The ratio of luminous to total radiation of the lamp was taken at different angles below and above the horizontal. The value of the mean hemispherical efficiency is found to be 8·4 per cent. The mean efficiency of the ordinary arc is about 10 per cent. The mean efficiency of the incandescent lamp, according to Merritt, is rather below than above 5 per cent. The value obtained in the test of this new light therefore lies between those of the two present forms of electrical illumination, approaching, however, more nearly that of the arc. While it is true that the average efficiency of the electric arc in open air nets about 10 per cent., it is questionable whether in commercial practice in this country this value is often reached. The writer has made tests of a standard brand of arc light carbon where the efficiency was only 7½ per cent.

Tests were made to determine the effect of initially coating the internal surface of the cylinder with various ingredients other than carbon. No marked difference in the efficiency was discovered. The distribution of light differs considerably from that of the ordinary arc. Especially is this true at angles greater than 50deg. below the horizontal. To the naked eye the intensity of luminous radiation does not seem to vary much from 20deg. to 60deg. below the horizontal, while in the arc the change is very marked between these limits. The results of tests show that the mean hemispherical candle-power of the ordinary arc averages about 600; the mean watts candle ·84, or 888 candles per electrical horse-pow

TO CORRESPONDENTS.

THE B. A. MEETING.

From Edinburgh to Nottingham, though twelve months intervene, is the cry of the British Association, whose annual meeting commences next Wednesday at the latter town. It was in 1866, under the presidency of Sir William, then Mr. W. R. Grove, a man whose name will live long in scientific history as one of the first to attempt the centralisation rather than the diversifying of scientific thought, when the meeting previously met at Nottingham. A very interesting study might be founded upon the cyclic tendencies of scientific discussion. The rampant subject around the year 1866 was—dredging. Since then we have had other subjects much more prominent, among which electrical matters shine conspicuous. Deep-sea sounding and dredging are, however, by no means unimportant subjects to the electrician, especially to those of the craft who are engaged in cable work. They must know something of the depth of water and the character of the bottom, and the more they know the better for their work. Perhaps, if the truth was known, such expeditions as those of the Silvertown Company to the African and American coasts have done more to delineate the surface of the ocean bed around these coasts than all the governments combined. In this connection, then, the work of the British Association in fostering expeditions of the "Challenger" kind, cannot fail to deserve recognition. From 1866, coming to 1893, we are fain to ask if there seems to be foreshadowed any important subject which will be discussed in the interests of electricity, and, in answer, to say there seems to be none. That there will be some papers discussing questions relating to the borderland of science is known, but for all practical purposes anything said of this dreamland is only of passing interest to the world of to-day. The real knowledge obtained is small, even if there be any reality, the attempt to investigate being more from the desire to form theories to fit facts rather than to classify facts and obtain laws. Was it not Max Muller, in his admirable lecture on the "Science of Language," who describes all science as passing through three stages—the empirical, the classificatory, and the theoretical. Sometimes it appears to us as if electrical science was a jumble of the three, its votaries being either empirical, classificatory or theoretical just as it suits their purpose, and with drum ecclesiastic would cram their views down the throats of hearers. It is in this particular that we cannot countenance the ordinary electrical preacher of the day. He arrogantly claims absolute infallibility, and will not admit of doubt, though appeal to time will show that really his views are as changeable as the weathercock. Hence we venture to question the wisdom of too easily falling a prey and accepting the conclusions of those who make excursions into the borderland of science. Their work is honest, it is interesting; but a few more such excursions, a little extension of our knowledge, will probably show that the conclusions put forward require modification. The secrets of Nature must be very simple indeed if the *savants* of the nineteenth century are

to solve them. We must leave a little for future generations. It is well to know that from the forecast of the address of the sectional president of Section A, he is not so sanguine of finality as some of the less able but more ardent physicists seem to be. He is to discuss the properties of the ether to fulfil the requirements of our present views relating to light and electricity, and try to show by such discussion whether science is able to predict what electricity is. The answer, according to an inspired source, is likely to be, "Man knoweth not." But of this, more anon. Unfortunately, with one exception—Section G—the sections are not worked on business principles. This is the fault more of the contributors of papers than of the secretaries. The men who contribute to Section A are too big to bully, so that frequently the papers are not completed before the meeting, sometimes not even when read, and to properly report such proceedings is a task beyond the powers of a literary Hercules. The members supporting Section G are of a different class—they understand business matters, and with solitary exceptions make our task as easy and as pleasant as is possible. Although, then, the outlook does not seem favourable to much new electrical matter, we hope in the usual course of things to give the presidential addresses that at all bear upon matters with which this paper is concerned, as well as the papers that may be discussed. To those of our readers who do not know Nottingham we would say that the local committee has made excellent arrangements for the pleasure side of the show, and that, though Nottingham itself may be deficient in interest, the surrounding district will well repay examination.

FESTINA LENTE.

Nowadays there is a wide-spread feeling, sometimes emphatically expressed, that the name of "Stick-in-the-Mud" is a suitable appellation to confer upon anyone who does not wear seven-leagued boots in travelling along the highway of life; but one may surely be pardoned for a wish to maintain a steady pace, if slow, seeing that, after all, there is no particular object realised, to the world, by getting to our journey's end any sooner. Apparently, it is not even as though humanity or the conditions of existence were very greatly benefited by quickening the pace of life; at least, our social system must be completely wrong if the progress of generations can give us really nothing better than a more rapid rate of living. To desert theory and discuss prosaic facts, what is the special advantage of travelling at an average speed three or four times as great as that which was customary a hundred years ago? Of course, to ask such a question is to exhibit a somewhat marked reactionary spirit; but is it altogether unreasonable? Let us assume that the "zeitgeist" continually calls for developments, and makes us do more in a given time than our grandfathers: is this spirit an evil one due to artificial conditions, and, therefore, probably as bad as they make them; or does it arise from the action of natural laws which we may not like, but which somehow or other insist in the end upon obedience?

This nice little problem is to our mind worthy of development and solution, even so far as the present conditions of life pertain: how much more, then, will it be affected by a consideration of what is likely to come in the future, if things go on as they have done. To-day we travel on the main-line railway expresses, driven by reciprocating steam locomotives, at an average speed all told of from forty-five to fifty miles per hour, and can get through more space (and presumably more work; but let us not be too sure of that) than our grandfathers, in the proportion of four to one. Our grandsons, however, will not—according to some people—be contented with this, but must live at a still higher pressure: therefore let preparations be made for them by scheming out plans and designs for transit across the country at speeds more than double those now given by express services.

Of course, if a man desires to live in the memory of his descendants as a go-ahead individual, who dreamed away his life in the details of what was to come, he could not do better than use the seven-leagued boots of which we have spoken, and so keep a long way in front of everybody else on an open road, not, like the true inventor, finding out a new course over a district hitherto trackless.

In another column are given some details of a scheme just introduced to public notice, and dealing with the idea of rapid transit at a speed of one hundred and fifty miles per hour. Putting the matter in a plain outspoken way, what, we would ask, is the earthly good of developing such a scheme in this fashion, and under present conditions? What financiers would to-day, or to-morrow either, care to associate themselves with the proposal, or to subscribe a penny towards it, on a scale at all commensurate with the suggestion? Is there any public demand for speeds so great as this; and, above all, could a line of the type proposed be built for a reasonable sum (including parliamentary charges, cost of land, etc.), and then be certain of traffic enough to pay even moderate dividends?

If the object of this proposal is to develop electric traction, the promoters might with advantage begin more modestly, and help to foster and create electric tramways, first of all, to run at a speed of ten, or even twenty miles an hour. Short electric railways acting as feeders of the main lines would then follow as experience grew and the electric railroaders became more confident; but to our mind it is absolute waste of time and energy to work out, even on paper, the details of a main-line service calculated at once to make a huge step forward, and involving the exercise of such knowledge and skill as, in point of fact, can only come through years of preliminary work on a smaller but gradually increasing scale.

No one would deny that a speed of one hundred and fifty miles an hour can be achieved on an electric road; there is no particular reason, indeed, why the promoters should have contented themselves with this figure. While ... at it they might

just as well have gone a little higher and made it two hundred and fifty. The difference is only one of degree—and years.

The time is not ripe for such proposals, and they might therefore be dismissed with a wave of the hand were it not that the man in the street is attracted by such an exercise of the creative faculty, and therefore deems a less important and imposing plan to be naught. The man in the street is wanted to give his support and subscribe his pence and pounds to the tangible and immediate systems that are crying out for development—the street tramways first of all—that is, if satisfactory proof can be shown that to work them electrically is to work them profitably. Then the short railways may follow, and possibly, in the far future, our main lines will be converted by the genius of Faraday to be used at speeds only limitable by the purchasing power of a sovereign. Unlike Gilpin's chronicler, we are, however, thankful that we shall *not* be there to see.

CHICAGO.—August 25th.

The following is the resolution on units adopted by the Electrical Congress:

Resolved, That the general governments represented by the delegates in this International Congress of Electricians be and they are hereby recommended to formally adopt as legal units of electrical measure, the following:

As the unit of resistance, the international ohm, which is based upon the ohm equal to 10^9 units of resistance of the initial C.G.S. system of electromagnetic units, and is represented by the resistance offered to an unvarying electric current of a column of mercury at the temperature of melting ice, 14·4521 grammes in mass, of a constant cross-sectional area, and of a length of 106·3 centimetres.

As a unit of current, the international ampere, which is $\frac{1}{10}$ of the unit of a current of the C.G.S. system of electro magnetic units, and which is represented sufficiently well for practical use by the unvarying current, which, when passed through a solution of nitrate of silver in water, in accordance with accompanying specifications, deposits silver at the rate of 0·001118 of a gramme per second.

As a unit of E.M.F., the international volt, which is the E.M.F. that steadily applied to a conductor whose resistance is one international ohm will produce a current of one international ampere, and which is represented sufficiently well for practical use by 1,000/1,434 of the E.M.F. between the poles or electrodes of the voltaic cell known as Clark's cell, at a temperature of 15deg. C., and prepared in the manner described in the accompanying specifications.

As the unit of quantity, the international coulomb, which is the quantity of electricity transferred by a current of one international ampere in one second.

As a unit of capacity, the international farad, which is the capacity of a conductor charged to a potential of one international volt by one international coulomb of electricity.

As the unit of work, the joule, which is 10^7 units of work in the C.G.S. system, and which is represented sufficiently well for practical use by the energy expended in one second by an international ampere in an international ohm.

As the unit of power, the international watt, which is equal to 10^7 units of power in the C.G.S. system, and which is represented sufficiently well for practical uses by the work done at the rate of one joule per second.

As the unit of induction, the henry, which is induction in a *circuit* when the E.M.F. induced in this circuit is one international volt while the inducing current varies at the rate of one ampere per second.

There was also presented a report of the committee appointed to consider the question of standards of light. The committee says it has had much discussion upon the various forms suggested for standards, and in particular upon the two special forms of lamp known respectively as the amyl-acetate lamp of Von Hefner Alteneck and the pentane lamp of Vernon-Harcourt. It was unable to arrive at a vote recommending either, however, and therefore recommended that all nations be invited to make researches in common on well defined practical standards and on the convenient realisation of the absolute unit.

THE PRACTICAL MEASUREMENT OF ALTERNATING ELECTRIC CURRENTS.*

BY PROF. J. A. FLEMING, M.A., D.SC., F.R.S.

LECTURE IV.

MEASUREMENT OF ALTERNATING-CURRENT ENERGY.

In this fourth and last lecture I propose to discuss the practical measurement of alternating current energy and alternating-current quantity. In so doing we shall begin by dealing with the easier problem in the measurement of such quantities—viz., when the circuits to which the power or current is being supplied are non-inductive—and then proceed to consider the more difficult case in which the circuits are inductive circuits, such as the primary circuits proceeding out from alternating current stations.

Instruments for the measurement of alternating current energy or quantity are called simply meters, and they are classified into ampere hour meters and watt hour meters. A complete classification of all the different forms of meter already invented would be a rather difficult thing to make on a perfectly correct basis. I shall give you presently an approximate classification. In the first case we will consider the simplest forms of meter, which may be called graphic ammeters and wattmeters.

Of these two, the Holden ammeter and Mengarini wattmeter are good examples. In these instruments an arm carrying a pen is displaced over a paper-covered drum, which is revolved uniformly in 24 hours by a clock. The motion by which the pen is displaced is regulated by a part of the instrument which is simply an ammeter or a wattmeter, and the displacement of the pen is proportional to the current or the power passing through this measuring part. When, therefore, the diagram is cut off and unrolled, we find on the paper a curve which represents, by its ordinates, either the power or the current at any instant; and, if the whole area of the curve is integrated, then such area represents the whole energy or quantity which has passed through the meter in 24 hours. These instruments have the advantage, therefore, that we practically record two quantities at once; and they serve two purposes of indicating the instantaneous current or power and the total current quantity or energy, but they have the disadvantage that they are not self integrating.

Next in order of simplicity are the self integrating ammeter and self integrating wattmeters. One of the simplest of those self-integrating ammeters, but which is, however, available only for the measurement of alternating-current quantity, is the well-known Shallenberger meter.

Before me on the table are a series of meters, lent by different firms, and these I will put in motion, in order that you may see the movement.

The principle of the Shallenberger meter is not a difficult one to understand. It consists (see Fig. 1) of a small transformer, one coil of which we may call the primary, and which is in series with the circuit in which the current to be measured is flowing. The core of this transformer consists of a little soft iron disc, which is capable of revolving on an axis. This axis is geared at the top with a counting mechanism, which records the number of revolutions of the disc, and at the bottom there is a vane or fan of thin aluminium, which serves to retard the rotation of the disc.

The secondary circuit of this transformer consists of a small coil of copper, which is closed upon itself, and which is placed with its axis inclined at 45deg. to the axis of the primary coil. When the primary current flows through the primary coil it does two things—it magnetises the core, and it induces a secondary current in the closed secondary circuit. It is not difficult to show that the phase of this secondary current must be about 90deg. behind the phase of the primary current, and also that the magnetism of the iron core, which is in a direction at right angles of the plane of the primary coils, also lags in phase behind the primary current by about 90deg. The magnetism of the core and the induced secondary current are, therefore in step, and are in such directions that the axis of the disc is always being pulled round by the induced field of the secondary coil. If, then there were no friction of any kind, the iron disc would be continually accelerated in speed, but since the air friction varies approxi-

* Cantor lectures, delivered before the Society of Arts.

mately as the square of the velocity, and since the mean driving force is proportional to the mean square of the current strength, it follows that the total number of revolutions which the disc makes in any given time is proportional to the total mean quantity or ampere hours which have passed the primary circuit. The meters can therefore be calibrated by a constant in such a way that they read directly ampere hours, and if the pressure between the mains is kept constant, they may be graduated to read in Board of Trade units.

These meters are very simple to construct and very fairly accurate in performance, and they have, therefore, come into extensive use. The velocity of the disc being at any time proportional to the mean current passing through the meter, we can, if the current is kept tolerably constant, employ the instrument as an ammeter. By moving the position of the secondary coil, a little adjustment can be made in the meter for change of frequency, and the meter can be calibrated for the particular frequency for which it is intended to be used.

Taking the particular meter before me, which is a 10-ampere meter, it starts with less than half an ampere and reads up to 10 amperes. The greatest variation within this limit in accuracy of reading is about 3 per cent. The meter has, therefore a range of about 1 to 25, and with care in adjustment can be made to read more accurately than the above mentioned figure.

The next meter in order of simplicity, and very similar in principle to the Shallenberger, is the Wright-Ferranti meter. It is also a self integrating ammeter; it measures at any instant the mean square current, and gives us the mean quantity which is passed through the meter. Looking at the diagram, Fig. 2, we see that the indicating part of the meter consists of a wheel with a light iron rim. This wheel is nearly embraced by two curved horns of laminated iron. These horns spring from the corners of a rectangle of laminated iron. This laminated iron rectangle is wound over on all four sides with two coils of wire. Through one of these coils the current to be measured passes, and the other coil is a shunt coil, the function of which I shall describe presently. The arrangements of the coil are such that any moment the ends of the curved horns are opposite magnetic poles. On these curved horns are placed copper rings. When the alternating current passes through the series coil it creates alternating magnetism in these curved horns, but owing to the eddy currents of the set up in these embracing rings, the magnetic lines of force are thrust outwards, making a lateral leakage field, which travels up the horn. This leakage field induces eddy currents in the iron disc, and the disc is thereby repealed in virtue of the electromagnetic repulsion set up between the horn and the wheel. An experiment to illustrate this repulsion can easily be shown.

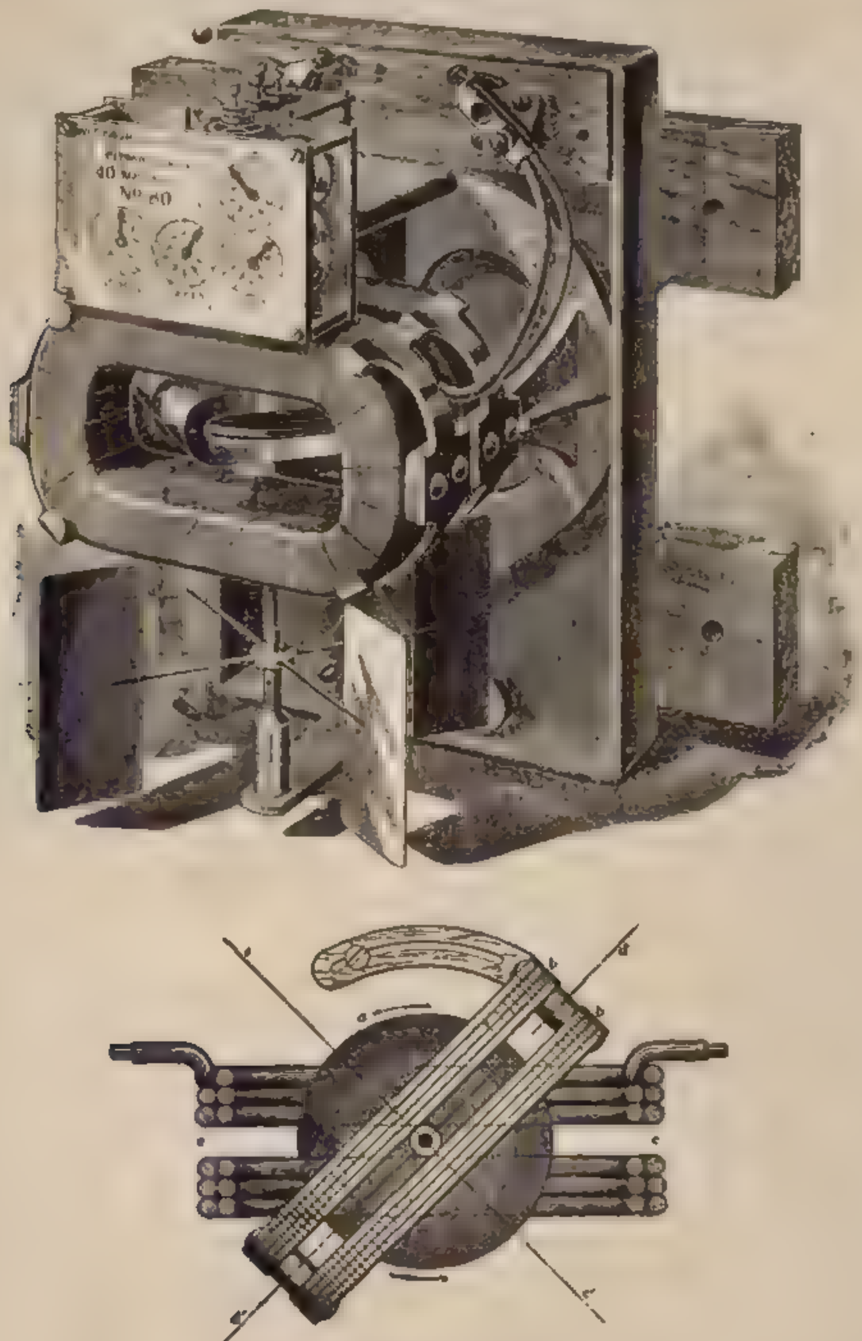

FIG. 1.—Shallenberger Meter.

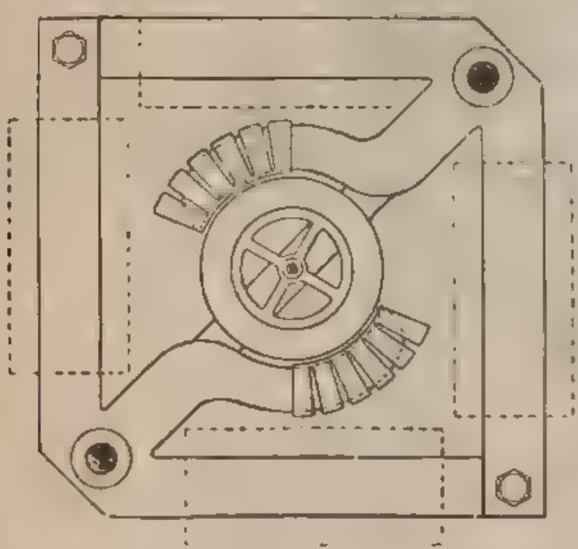
In front of me is a large alternating-current magnet. Across the top of this magnet I place a laminated iron bar. The laminated iron bar is embraced at intervals with copper rings. If I set the alternating current magnet in action, and if I hold the soft iron disc mounted on a pivot near to the laminated bar, it begins to revolve rapidly. We may explain this in another way, by saying that there are a series of alternating magnetic poles running up the iron bar, and that these alternating current poles produce other induced poles in the iron, and so drag the disc round. All these effects of electromagnetic repulsion were more fully explained by me in a lecture once given in this place.

Returning, then, to the Wright-Ferranti meter, you will note that the axis which carries the wheel has upon it four aluminium

or mica vanes, and is also connected at the top to a counting mechanism. When an alternating current is passed through the meter it tends to drive the wheel round with a speed which is proportional to the mean square strength of the current, and, therefore, it follows that the number of revolutions made by the wheel at a given time is proportional to the mean quantity in ammeter hours which has passed through the meter at that time.

The meter before me is a 20 ampere meter, which starts with a current of about half an ampere, and reads up to 20 amperes. Within these limits the greatest deviation in accuracy is only about 1·8 per cent. Both the Shallenberger meter and the Wright-Ferranti meter require to be calibrated for the particular frequency for which they are to be used, and they only give Board of Trade units provided that the pressure is kept constant between the supply mains. The meter really reads quantity directly, and power only on the assumption of the constancy of pressure.

I mentioned a moment ago that there were two circuits on the electromagnet, and that one of these was the shunt circuit. The



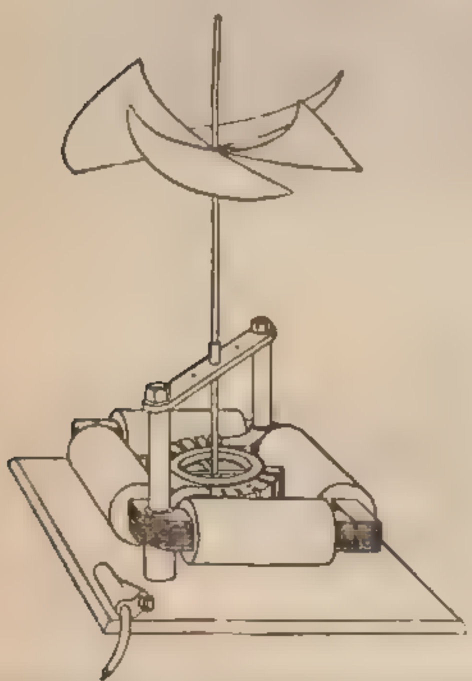


Fig. 2.—Plan and General View of Wright Ferranti Self-Starting Alternating Motor Working a Fan.

function of this circuit is to supply the driving force which overcomes the friction of the counting train. If this shunt circuit were not present, there would be a frictional resistance to be overcome before the meter would start at all.

Another meter, of a tolerably simple character, also intended for measuring ampere hours, is the windmill meter, invented by Prof. Forbes some years ago. In that meter, Fig. 3, there is a coil of wire, which was heated by the current passing through it. This heated coil generates an upward current of air, and this upward current of air is made to turn round a very delicately constructed windmill with mica vanes. The counting train attached to the windmill records the number of turns in a given time. Although this may seem to have been a somewhat unpromising principle to apply, yet the meter in itself gave excellent results.

We turn next to the consideration of the second great class of meters—namely, the watt hour meters which are self integrating. These self integrating watt hour meters may also be divided into *two classes—continuously* and intermittently integrating.

Taking the last class first, this is well represented by the Frager meter. In this meter there are two distinct parts: first, the watt meter part, which measures at any instant the power; and the integrating part, which integrates at intervals the power and the time. The wattmeter part, as you will see, on looking at the instrument, consists of a wattmeter having a thick coil, which is a series coil, and a movable coil, which is suspended by a steel wire which is a shunt across the circuit. The terminals of the shunt coil are connected to the two sides of the mains, and the current to be measured is passed through the series coil. Attached to the movable shunt coil is a long arm, and the displacement of this arm varies with the power passing through the instrument. Adjacent to the wattmeter, and fixed on the same base, is an electrical clock, which drives round a curved plate of metal, which is technically termed "the snail." On the end of the long projecting arm attached to the wattmeter is a small steel point. As the snail is turned round it passes underneath this arm, and if this arm is displaced, the length of the path of the pointer, when travelling over the snail, is proportional to the power passing through the wattmeter. The snail plate is so suspended that when the pointer passes over it, it presses it down, and makes an engagement between the snail and the counting mechanism.

At each revolution of the snail the counting mechanism is turned round by a number of revolutions which are proportional to the mean power or watts passing, and hence the total number of revolutions in any given time is proportional to the watt-hours which have passed through the meter. The snail revolves round in a period which is about three minutes, and hence the record is, as it were, made of the power passing through the wattmeter only at intervals of three minutes. If the current which is to be measured does not vary very rapidly, such an intermittent recording meter may be made to give very accurate results, but there are many cases, such as in theatres, where the amount of current passing through the meter is very irregular and rapidly varied. Under these conditions the wattmeter needle is thrown about in such a manner that the actual power recorded on the dials at every revolution is not always the true mean power passing in the interval between two revolutions and the readings of the meter may therefore

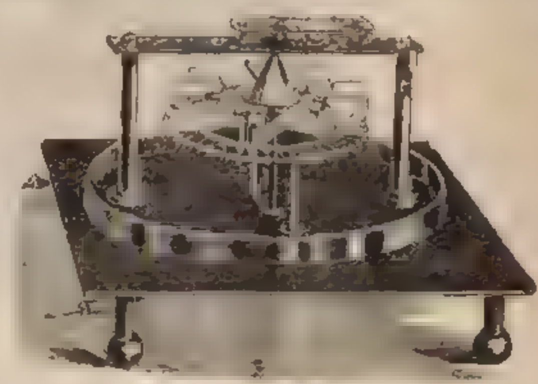

Fig. 3.—Forbes Meter.

become very erroneous. Practice has confirmed these inferences, and although the Frager meter is under some conditions of use a very accurate meter, there are other conditions under which its readings are not to be depended on.

Coming next to the continuously recording watt-hour meters, we reach that class of meter which may be said to be the best adapted for general wants, and one of the most efficient of these continuously recording watt hour meters is the one invented by Prof. Elihu Thomson. The Thomson recording wattmeter is, as you will see from the specimens before us, a wattmeter in which one coil, called a series coil, carries the current to be measured. These series coils really form the field magnet of a very small electromotor. The armature of this motor is a beautiful one having a small commutator and brushes of the usual kind, and this armature circuit, together with the external added resistance, constitutes the shunt circuit of the wattmeter. When the meter is attached to a circuit, the main current of which passes through the series coils, and the shunt coil being attached to the two mains, the armature begins to revolve. The shaft which carries the armature carries also a copper disc, which is embraced by three horseshoe magnets. When the disc revolves, eddy currents are set up in the disc which retard its motion. The number of revolutions of the disc in a given time is recorded by the counting mechanism attached to the shaft. Then since the force driving the armature round is at any instant proportional to the power passing through the instrument, and since the retarding force is proportional to the velocity, it follows that the number of revolutions in a given time represents the watt hours that have passed through the meter. In order to overcome the constant friction of the train, there is a compound winding on the field magnet, consisting of a few turns of the shunt coil, which is arranged in such a direction that the driving force due to the fixed and movable shunt winding tends to overcome the permanent friction of the armature shaft. By properly treating the permanent magnets, it is found that they retain a constant magnetism for long periods of time. The meter is so arranged that when working on a 100-volt circuit, the shunt coil has a resistance of 1,000 ohms altogether, and takes, therefore, ·1 of an ampere.

The loss in the meter, therefore, is only 10 watts, which is the power taken up in driving the meter. By properly arranging the shunt coil, it is possible to make the constant of this meter perfectly constant for a very large range of its action, and one great advantage which this meter has is that it can be employed with both alternating and continuous currents. When properly adjusted, this watt hour meter is capable of very great accuracy in the measurement of alternating current energy.

There are several other meters, which time will hardly permit me to describe fully, but a brief allusion may be made to them.

One meter before me is called the Brillie meter, and is of the type of the Frager meter, that is to say, it is an intermittent recording wattmeter. Another meter, of which I spoke at the beginning of the lecture—namely, the Mengarini recording wattmeter—is also before me. This last meter has been extensively employed on the alternating-current circuits of the Rome electric lighting station.

Reviewing, then, the whole of these meters, we may say that a rough classification of meters for the measurement of alternating currents may be made as follows:

1. Graphic recording ammeters.
2. Graphic recording wattmeters.
3. Continuously recording ampere hour meters.
4. Intermittent recording wattmeters.
5. Continuously recording wattmeters.

We may ask ourselves at this stage what ought to be the characteristics and requirements in a good commercial meter for the measurement of electric energy supply to houses for lighting and other purposes. Most persons without experience would probably say that the first requirement in a meter is accuracy; but as a practical matter accuracy is not of so much importance as that the meter should never go far wrong. A type of meter which is capable of measuring, under some conditions, to ·1 of accuracy, and at other times is liable to make errors of 150 per cent. in actual practice, is not nearly so useful as a meter which will not read closer than 1 per cent., and yet which, in actual practice, never proves to go more than 3 per cent. wrong.

The next condition which a meter must comply with is that of the consumption of small power. Since the meter is connected to the circuit continually, if it absorbs power, the sum total of all these consumptions may amount to a serious item. We have pointed out, in speaking of voltmeters, that a continuous power absorption, say of 20 watts, during the whole year, amounts to a yearly consumption of 160 units of electric energy, and that, therefore, small power consumption is certainly an important item in appraising a meter.

The third great requisite is, that the meter ought not to require elaborate care and delicacy in fixing, and that it ought to be hardy enough to be easy of carriage. House meters have to be fixed in places which are sometimes subject to vibration and dampness, etc., and a meter for house purposes ought, therefore, to be hardy enough to stand those conditions.

The fourth condition is, that the meter must be so constructed in principle as not to be capable of being easily tampered with, or its indications made to vary, even when enclosed in a lock-up case.

To the above requirements ought, of course, to be added the broad and general conditions of simplicity of structure and cheapness in price, as far as consistent with good workmanship.

I now turn to the important subject of the measurement of alternating current power when supplied to inductive circuits; in other words, we have to study alternating current primary meters. In the distribution of alternating currents for commercial purposes, not only is it necessary to be able to measure the power or energy supplied to the consumer on the lamp circuits, but it is also necessary to be able to measure the power and energy sent out from the alternating current station which is supplying generally, transformer circuits. Hence we have to consider the special difficulties of making such measurements on circuits which have a considerable self induction, or in which the power factor of the circuits is below unity.

During the past year or two I have paid particular attention to this subject in a long series of researches on the efficiency of transformers, and have thereby been led to study most of the various methods which have from time to time been proposed for measuring alternating-current energy.

I do not propose to occupy the time—already brief—in discussing any of the methods which, however well they look on paper, are yet, for some reason or other, inapplicable in practice, but to describe the methods which have proved themselves in my experience satisfactory and practicable in making these measurements. I have found that the two instruments for this purpose which are capable of being employed with very satisfactory results for the measurement of alternating current energy on inductive circuits are the Thomson recording wattmeter and the Mengarini wattmeter already described.

Generally speaking, these measurements have to be made on high tension circuits. Take, for instance, the very common case of an alternating current station, supplying alternating current at a pressure of 2,000 volts on transformer circuits. One method of employing either of the above wattmeters as energy meters would be to place a non inductive resistance of sufficient magnitude in series with a shunt coil, and to put the series coil in the series with one of the primary mains.

In such an arrangement there would be certain disadvantages. In the first place, the Thomson recording wattmeter takes a current of about one tenth of an ampere through the shunt, and hence we should have to add to the shunt coil, the resistance of which is about 1,000 ohms, another 19,000 ohms of non-inductive resistance, and then when this was done the power wasted in the whole of these shunt circuits would be 200 watts. If these shunt circuits were kept connected to the mains throughout the whole year, the waste of energy in these shunt circuits would be something like 1,600 Board of Trade units, and if we reckon the manufacturing cost of these at only 2d. a unit it would cost something like £12 per annum merely to supply the shunt circuit with current. But this difficulty can be got over and also the difficulty of constructing a large non inductive resistance of 20,000 ohms, sufficiently well divided up not to be in any danger of breaking down with 2,000 volts pressure by the adoption of a transformer to excite the shunt circuits in the way described in my last lecture. A small transformer is employed, transforming down from 2,000 volts to 100 volts, and as this transformer is only to supply one tenth of an ampere on its secondary circuit, it can be made very small, not more than, say, a tenth of horse power in capacity. It can, therefore, be made to waste not more than about 10 to 20 watts in itself. This transformer has its primary circuits connected across the primary mains, and its secondary circuit is connected across the terminals of the shunt circuit of the Thomson wattmeter, and so joined up that the current in the shunt circuit of the wattmeter is in the same direction and has the same magnitude as if the wattmeter were joined up simply on a 100 volt circuit in the ordinary way.

The wattmeter in itself only wastes about 10 watts in its shunt circuit, and, therefore, the whole arrangement of the transformer and wattmeter can be made to waste not more than, say, 25 to 30 watts, instead of 200, and reduce the cost of up keep to something like 200 units a year instead of 1,600. The primary current going out of the station is then taken through the series coil of the Thomson wattmeter, and in order to keep all the parts of the wattmeter at the same potential, one terminal of the secondary circuit, and the little transformer, is also joined up to the primary main on the side nearest to it.

It is usual to mount the transformer and wattmeter on one board, and then to insulate the whole of this board well. The first step is to calibrate the wattmeter. This can be done most easily on a 100 volt circuit by passing through the meter known powers, and observing the reading of the dials. The constant of the meter then has to be multiplied by the transformation ratio of the small transformer in order to obtain what may be called the high tension constant of the meter. When this is done, the meter can be set up in the station in such a way that the whole current going out of the station passes through the meter and the engineer can, by taking observations from day to day, record the whole number of units which have been sent out from the generating station on the primary circuits in any interval of time. In exactly the same manner I have found it possible to employ a Mengarini wattmeter coupled with a transformer and placed on the primary circuit. This has the advantage that it not only enables us to record the whole of the energy going out of the station in a given time, but to know at any instant the primary watts.

Before placing confidence in either of these two methods, I made a very careful series of observations on an inductive alternating-current primary circuit, in which I employed the Thomson self-integrating wattmeter as above described, to measure the whole number of units sent out along that primary circuit in four hours, and at the same time observations were made on the same circuit by means of a wattmeter to obtain the power sent out at intervals of minutes. When these observations were compared and reduced, it was found that the power sent out in four hours, as determined by the observations, was 66·924 units in the wattmeter, and the energy given by the self-integrating Thomson wattmeter in the same time was 66·946. It thus became evident that the Thomson recording wattmeter was capable of giving very accurate results as a primary wattmeter, and that there is no reason whatever why the record of the primary energy sent out should not be made in alternating current stations with the same accuracy as in the case of continuous current stations.

To complete arrangements it would be desirable, in the case of an alternating-current station, in order to enable the engineer to know exactly what the result of his working is, to act as follows:

On the primary should be placed in the first place, an ammeter, capable of measuring alternating currents and giving the mean square value. In the second place, an electrostatic high tension voltmeter should be connected across the mains in order to give the high-tension volts. In front of this instrument should be placed a Mengarini wattmeter and a Thomson self recording wattmeter, the whole primary current from the station going through the series coils of these instruments. The shunt circuits of these instruments should be excited by a small transformer, transforming down from a working pressure of 100 to 50 volts. These instruments would then enable the engineer, by daily readings, to record, first, the energy sent out of the primary circuits in Board of Trade units in any time; secondly, the power being sent out at any instant measured in watts; thirdly, the primary current being sent out at any instant, and the primary pressure, and, therefore, from the product of these two, the apparent power being sent out at any instant; and, fourthly, from the readings of the real and apparent power, the power factor of the station could be ascertained at any instant.

By comparing these readings with the sum total of the house meters taken at any intervals, the engineer would be enabled to know the efficiency of distribution of his alternating current station, and to reckon out, not only the cost of the unit sold, but the cost of the unit generated, and to watch and know the effect of any improvements that are made in the transformers on the system.

It is only by adopting such methods of measurement that engineers in charge of alternating current stations will be able to remove the reproach which is sometimes hurled at them, that they have no means of measuring the energy or power they are supplying, or of knowing how much of what they make is sold.

In concluding this course of lectures I have to thank all those firms and gentlemen who have lent me the numerous instruments which I have been able to exhibit to you here. My endeavour has been to put the subject before you in as practical a manner as possible, and to give you, as it were, the cream of practical experience, rather than the skim milk of mere theory. It would have been difficult to do this without the practical exhibition of instruments of various types, and I do not think that any single instrument of practical importance has been mentioned an example of which has not been placed before you. The practical measurement of alternating currents may be more difficult, in many respects, than the measurement of continuous currents, but, at any rate, we have the satisfaction of knowing that it is now placed on an equally certain and satisfactory basis.

THE MUNICIPALITIES AND THE TELEPHONE.

The application of the Glasgow Corporation for a license to work telephones in their city (recently referred to in the *Times*) will probably oblige the Government to consider once more the whole question of telephone administration. This application is, indeed, but one of many indications that the public, and those most powerful representatives of the public, the municipal corporations, are at once tired of the present state of things and dissatisfied with the arrangements promised by the Government last year. Of the existing telephone service there seems to be but one opinion. Not only is it very dear, it is also very bad. While the annual rent of a telephone on the Glasgow exchange is £10, in Canada it is £4, and in Melbourne £6, while in Holland it varies from £6 to as little as £2 10s., and in Stockholm between £4 and £5 is paid for the power of conversing over a district 40 miles in length. But the quality of the service arouses still louder indignation. One Glasgow councillor, in the course of the recent discussions, said he had been trying to speak to a firm for more than a fortnight, and had not yet succeeded while another had given up the telephone because he was not prepared to use the bad language necessarily incidental to attempts to carry on a conversation. One cause of these difficulties is well known. Telephones can only be worked efficiently on a double-twisted wire, forming what is known by electricians as a completely insulated metallic circuit. The telephone companies have never thought fit to incur the expense of such a system, and the consequence is that talking over their wires in any large town is made vexatious, difficult, and sometimes impossible by the buzz of conversations on other wires. At the same time, the companies have consulted economy by running all their wires overhead, and thus covering every large town with a metallic web, harmless enough under ordinary conditions, but annoying to the householders whose chimneys and roofs are made use of, and occasionally in a peculiar state of the weather dangerous to life and limb. Moreover, this network of wires has been erected by companies possessing no statutory powers and without the leave of the municipal authorities. At a time when municipal life gains in vigour every year, such a slight has been deeply resented, and the National Telephone Company, which has now absorbed all rivals, has become unpopular with mayors, town councils, and town clerks. There is yet another drawback to the present system. The telegraph and the telephone ought to supplement one another. The telephone has the advantage of despatch and of being at hand when wanted: the telegraph excels in furnishing a written record of a message, in privacy, and in applicability to varying circumstances. There are many cases in which the two systems might be combined with advantage. A subscriber to an exchange may like a particularly important message to be delivered to his correspondent in writing, but at the same time it may be more convenient to him to use his own telephone than to send a telegram to a post office. There is no reason whatever why he should not speak his message to an exchange or a post office and have it delivered thence except that the telephones belong to a private company and the telegraphs to the State. If the company were allowed to deliver written messages, it would be for all purposes a telegraph company competing with the State, and, rightly or wrongly, the Government has thought it impossible to sanction such a competition. Hence the telephone has hitherto been used under limitations which go far to impair its usefulness, even had the mechanical arrangements of the telephone companies been what they ought.

Nevertheless, and notwithstanding these drawbacks, successive Chancellors of the Exchequer have been forced to lament a falling off in the telegraph revenue, and, suspecting the competition of the telephones to be one cause of this decline, the late Government determined upon the new departure explained in the Treasury minute of last year (House of Commons Papers, No. 229). These proposals reverse the policy of free competition initiated by Mr. Fawcett. They confine the telephone companies to certain areas, and reserve the rest of the country to the Postmaster General. In other words, while telephonic communication within towns—exchange business—is left to private companies, the Government proposes to take into its own hands all communications between town and town—trunk wire business. Trunk wires are to be open to all comers, and call offices, where persons not on an exchange may communicate with subscribers, are to be multiplied. At the same time exchanges and post offices are to be connected, so that telephonic messages may be spoken through to the post office, and thence transmitted as telegrams or letters. Moreover, the nuisance of overhead wires is to be checked by giving the telephone companies certain powers of laying underground wires.

In some respects these proposals (which of course can only be acted upon by agreement with the National Telephone Company) are an advance on the present system. It is something to establish public telephone wires from town to town and to combine the telephone service with that of the Post Office. But there are grave objections to the new policy. In the first place, it would secure the National Telephone Company in the enjoyment of a practical monopoly of telephonic communication in towns. The expressions of the Treasury minute on this head are clear:

"As to fresh licenses, no further license for the whole country will be granted; and even for a license to establish an exchange in a particular town no application will be entertained unless a formal resolution in its favour has been passed by the corporation or other municipal authority, and evidence given that there is sufficient capital subscribed to carry out the undertaking."

Now, it is obvious that if no further license for the whole country is granted, the company possessing such a license may safely defy any new local company, for, besides competing with it on its own ground, it will blackmail its subscribers when they try to communicate with other towns where exchanges of the one company which has a general license are established. In fact, then, the new arrangement would amount to a partnership between the Post Office and the National Telephone Company. Now, whatever may be said for or against a State monopoly, a monopoly in private hands, and used primarily to earn money for shareholders, is abhorrent to the sentiment of the present day. Nor is a partnership between the State and such a monopolist less objectionable. A partnership is only satisfactory where the partners have confidence in one another and work for the same object. The Government and the National Telephone Company would certainly not work for the same object while distrust and suspicion would as certainly take the place of mutual confidence. How can it be otherwise? The Government must before all things satisfy the public; the telephone company must before all things satisfy its shareholders. The Government is interested in earning a revenue from the telegraphs; the company has every motive for driving the telegraph out of the field. Neither the Government nor the company can ignore the possibility that some day the Postmaster-General may call upon the company to sell its enterprise. The company cannot but wish to enhance the value of the property it may have to sell; the Government cannot but wish to prevent any such increase of value. How is it possible that two such partners can work in harmony? Moreover, it seems probable that the partnership would be founded on a bad bargain for the Government. The Government is to take over trunk wire communication partly by purchasing the trunk wires of the company, partly by erecting new lines, and Parliament by the Telegraph Act of last year authorised the raising of a million of money for the purpose.

Suppose, when the million has been paid, the Government finds itself in possession of all the costly and unremunerative telephone business of the country, while the company is left in possession of that branch of the work which is inexpensive and profitable. Local letters and local telegrams are said to pay for those which travel far; but the State will have no local telephone messages, and though it will not be bound to uniformity of charge for long-distance work it will not be able to raise its charges indefinitely. And what complications may not arise between these suspicious partners as to the boundaries of towns and the distinctions between trunk wire and exchange business? Will not the company be the first to suggest to the inhabitants of a suburb that it is a monstrous thing that they should be compelled to pay a trunk wire charge for communicating with the exchange of the adjoining town? History will only repeat itself in such complaints. Anomalies of this kind obliged Mr. Fawcett in 1884 to abandon the principle of restricted areas and to give licenses for the whole country.

But these difficulties might for the present have been overcome, or at least overlooked, were it not for the question of wayleave. The telephone companies say they cannot get rid of the nuisance of overhead wires unless they are authorised to open streets and put their lines underground. So obvious is this conclusion that the recent Joint Committee of the two Houses appointed to consider how the balance might be held between the telephone companies and companies working electric tramways and railways went somewhat out of its way to recommend that "statutory powers be granted enabling telephone undertakers to lay their wires underground" (House of Commons Papers, 1893, No. 331). But to this the municipal corporations have the strongest objection, an objection recognised by the present law, which gives them an absolute veto upon the exercise of any such powers in their respective towns. They allege that to give a company which is in possession of a practical monopoly the right to take up streets without a concurrent obligation to supply the commodity in which it deals at certain rates and on certain uniform conditions is a departure from the best traditions of municipal government. They do not intend that the control of their streets shall be taken from them without some adequate consideration; and they have a strong dislike to the intrusion of a private company on any terms. It is to prevent such intrusion, as well as to deliver its citizens from the ills which they bear at the hands of the telephone company, that the Corporation of Glasgow has resolved, if possible, to take the supply of telephonic communication into its own hands; and there is much to be said for its proposal. If telephonic communication is not undertaken by the State, there is absolutely no reason why, if the ratepayers are agreeable, municipalities should not undertake the work. They already undertake the supply of water, gas, electric light, and the means of com-

munication by tramways; in fact, they undertake all enterprises which require the use of the streets. If telephonic communication can only be efficiently supplied by using the streets why should not the municipalities undertake that work also? The work they undertake they generally do well; they would probably do this work far better than any private company.

But there are two serious objections. One arises from the nature of the thing to be supplied. The telephone is used not only for speaking within the area over which the municipality rules, but for speaking to distant places with which the municipal authority has no connection. Assume that inter-town wires are in the hands of the Government; still, not only these wires, but the exchange wires of other towns, must be used. Every municipality, therefore, must agree with Glasgow in taking the telephone into its own hands—that is, it must carry on a commercial business at the risk of its citizens—or the telephone company will have to be dealt with; and that company will certainly know very well how to make charges and interpose difficulties which will still relegate the telephone millennium to a distant date. Still more serious is the difficulty arising from the fact that the telegraphs are in the hands of the Government. The telephone is only one kind of telegraph, and until both are in the same hands there must be competition between these rival means of communicating instantaneously with persons at a distance. It would be a misfortune to bring the State into competition with the municipalities; it would be a misfortune to place in many hands a business which should be in one. Parliament solemnly decided in 1868 and 1869 that the State should supply telegraphic communication. No one proposes to reverse that decision. As long as it stands it is an inconsistency to allow one very important species of telegraphic communication to be in the hands of private companies or local bodies. To levy a royalty upon other undertakers is not to undertake a business, and Parliament never authorised the purchase of the telegraphs merely to enable royalties to be charged and business to be *pro tanto* impeded and discouraged. The real lesson, therefore, of the proposal of the Glasgow Corporation is that the position created when licenses were granted to private telephone companies has become an impossible one. The advocates of the proposal have been careful to state that it is made only because the Government has made default in the work entrusted to it by Parliament, and by way of protest against the transfer of such work to private hands. The municipalities have no objection to the use of their streets by the Government; it is the intrusion of a private company to which they object. Let the Government take the telephones into its own hands and most of the difficulties vanish. A grievous mistake was made in not purchasing the telephone patents as soon as their value became apparent, and in creating a vested interest in a business which it had been deliberately decided was the business of the State. The public have said little about this mistake, because there has been a lurking suspicion that if the Post Office had acquired the telephone in early days very little more would have been heard of that wonderful invention. In these days of travel and communication the stifling of such an invention would have been impossible. But, however, that may be, the telephone has now established itself as a necessary adjunct of commercial life in England. The only question is, How can the public gain the greatest advantages from the instrument, having regard to the fact that the telegraphs are in the hands of the State? Many will hold the answer to be that the State should take the telephone also, even though it may have to pay somewhat dearly for past mistakes of policy. The alternatives are either to force the National Telephone Company into the streets of unwilling municipalities, or to bring these municipalities into the field of telegraph work as competitors with the State.—*Times*.

COMPANIES' MEETINGS.

DIRECT SPANISH TELEGRAPH COMPANY, LIMITED.

The ordinary general meeting of the shareholders was held on Friday last at Winchester House, E.C.

Sir John Pender, M.P., presided, and, in moving the adoption of the report, after expressing regret at the loss the Company had suffered by the death of their late chairman, Sir James Anderson, said that the accounts for the half year showed, after providing for debenture interest, a balance to the credit of profit and loss account of £4,645. The traffic receipts showed a decrease of £593 as compared with the corresponding period of 1892. The falling off in the receipts was chiefly due to the stagnation of Stock Exchange business in England, Spain, and France. It was somewhat remarkable that during the last six months, when things were at their very worst, submarine telegraph companies' shares stood a little higher in the market than usual; therefore, their position was sound. The working expenses were £130 in excess of those for the corresponding period of last year. The Company's cables, and the land lines in connection with them, had continued in good working order throughout the half year. The result of the half year's working was that, after adding the usual sum of £2,500 to the reserve fund, the balance of profit and loss amounted to £2,115. To that the Directors proposed to add £345 from interest on investments, and recommended the payment of the dividend at the rate of 10 per cent. per annum on the preference shares, and a dividend at the rate of 4 per cent. per annum on the ordinary shares. The reserve fund at the present time amounted to £35,936, £32,000 of which was invested and yielding them an average interest of 3½ per cent.

Mr. Edmund Ellinger seconded the motion, which was unanimously adopted.

LAMBETH.

At the last meeting of the Lambeth Board of Guardians the question of lighting by electricity was considered. It appears that some weeks ago the Guardians resolved to spend £30 upon obtaining the opinion of an expert as to the cost of lighting up the Lambeth Workhouse and Infirmary with electricity. Mr. Preece, an electrical engineer, was engaged to furnish the required information, and the following is the report he has addressed to the clerk on the subject:

"In accordance with the instructions contained in your letter of June 26 I have given careful consideration to the question of the lighting by electricity of the above-named buildings. In the consideration of such a question, naturally one of the most important points to review is the cost of the illuminant for which electricity is proposed to be substituted. In the case of the above-named premises this illuminant is gas. You have been good enough to supply me with the number of gas burners fixed, and the annual expenditure. The total cost during the year 1892 you state to be for the workhouse, £597. 13s.; for the infirmary, £1,047. 12s.—total, £1,645. 5s. But this is not all paid for gas used for lighting purposes; you also use gas for heating, cooking, and power. It is difficult without an intimate practical acquaintance with your heating and cooking appliances and the infirmary gas engine to determine what proportion of the total cost should be debited to these services, but an inspection of the appliances in question leads me to the determination that about £150 per annum will be the cost of the gas consumed in them, leaving in round figures £1,500 per annum as the actual cost of the lighting. I would further divide this sum between the two buildings as follows: workhouse, £550; infirmary, £950. The price paid is, I believe, 2s. 6d. per 1,000 cubic feet. We find thus that in the workhouse you consume 4,400,000 cubic feet, and in the infirmary 7,600,000 cubic feet of gas for lighting during the year. The number of burners in the workhouse is stated to be between 1,100 and 1,200. If we take the mean of the two figures (1,150) we shall probably be near the mark. Each burner therefore consumes 3,826 cubic feet per burner; while the 659 lamps in the infirmary consume on an average 11,530 cubic feet per burner. At five cubic feet per burner per hour it would appear that the workhouse lamps average 765 hours of lighting per annum; while the infirmary lamps burn 2,306 hours per annum on the average. I should judge from the inspection that I have made that we shall need to fix some 1,750 electric incandescent lamps of 16 c.p. or their equivalent in the two buildings under consideration: 1,000 will be needed for the workhouse, and the remaining 750 for the infirmary. We can safely afford to fix a less number of lamps than you have at present gas-burners in the workhouse; but the infirmary seems badly lighted in many of the rooms, and I think it would be wise to reckon on an increase in the actual number of electric lamps as compared with the gas jets now in use. With the easier manipulation of the electric light as compared with gas, we should get some reduction in the hours of burning. I will assume that the 1,000 lamps in the workhouse will burn an average of 700 hours per annum and the 750 lamps in the infirmary 2,100 hours per annum. The consumption of electrical energy on this assumption would be: in the workhouse, 42,000 supply units per annum; in the infirmary, 84,500 supply units per annum, total, 136,500 supply units per annum. The generating plant must be of sufficient capacity to maintain alight a large proportion of the 1,750 lamps at one time. I should assume that in no case would more than 1,600 lamps be lighted simultaneously. This would mean the employment of engines developing a total of 160 h.p. in their cylinders, and driving suitable dynamos to supply the lamps. At least one set of machinery must also be provided as a spare. I should propose on such an installation as this will be to fix three steam dynamo sets of 80 h.p. each. Two of these would supply the full load of 1,600 lamps, and one would only be run during the hours of lighter load (under 700 or 800 lamps), the third set being spare, but taking its turn regularly with the others as a working set. Two steam-boilers of large capacity would be needed. One of these would always be in reserve. The capital cost of the installation I estimate as follows:

Engines and dynamos	£2,100
Boilers	800
Steam pipes, pumps, and fittings	500
Lamp installation	2,625
Main cables	300
Contingencies	575
	say, £6,900

The working expenses would be:

	£	s.	d.
Cost of production at 2d. per unit	1,137	10	0
Maintenance of plant at 0·25d. per unit	284	7	6
Lamp renewals at 0·25d. per unit	142	3	9
	£1,564	1	3

say £1,600 per annum. To this sum must of course be added the interest on the capital expended, say, 3½ per cent. on £6,900 equals £241. 10s., bringing the total annual cost of the installation to £1,841. 10s., as against a gas bill of £1,500. *Per contra* to the increase in cost must be put the value of the better lighting in the infirmary. If only 600 lamps are fixed in the infirmary, giving a service about equivalent in lighting power to that now supplied, the annual cost will be reduced by £216. I have made no estimate of the cost of the structural alterations required to accommodate the machinery. I strongly recommend that if the work be

decided upon, that the two Galloway boilers that you contemplate fixing should be abandoned, and four new boilers of larger capacity be substituted for the boilers now in use. These should be worked together as one battery to supply steam for all purposes, including the electric lighting. The working pressure should be 120lb. to 130lb. to the square inch. It will be necessary to construct a new chimney for these boilers. This could be built upon the site of the present one, and the new boilers fixed in the same positions as the ones now in use. But a better arrangement would be to extend the boiler-room into the laundry by taking 16ft. off the end of the latter, which strip would include the site of the chimney. Under these conditions the chimney will have to be constructed on a new site outside. By following this latter course the extra space will enable us to fix four Lancashire (Galloway) boilers side by side. If only the present boiler space is available we shall have to fix economic or some marine type of boiler, which are not to my mind so satisfactory as the Lancashire type. Moreover, the heat of the stoke-hole, if placed central between two pairs of marine boilers facing each other, would be very great, and it would be difficult to get the men to work there. There will be no practical difficulty whatever in utilising a single battery of four boilers working at a pressure of 130lb. to the square inch on to the same range of steam pipes to generate all the steam you will need for all purposes whatsoever. An excellent position for the steam dynamo sets is the coal shed adjoining the laundry. This, I understand, can be spared. By utilising this shed for the purpose named you would have a nice compactly arranged plant, excellently situated for supervision, and at a fairly central point. There is no other position in the whole of your premises so well suited for the purpose. I am decidedly of opinion that an installation of electric light should be put in for your workhouse and infirmary. The extra cost over the present gas bill will be very small indeed, and your atmosphere will be saved from pollution. In the infirmary especially it will be found very much to aid your medical officers in securing that pure air so essential to the proper treatment of sickness, while in the workhouse the purer air of the rooms will certainly tend to improve the general health of the inmates.

It was moved and seconded that the Board should have nothing to do with the scheme, but this motion was lost, and an amendment postponing the matter for a month was carried.

GLASGOW.

The following memorandum has been issued with reference to the contract now in course of negotiation between the Post Office and the National Telephone Company, relating to the telephone system:

1. This contract is directly aimed against the corporations, county councils, and local authorities throughout the country.

2. All the telephone patents of importance have expired, which leaves the telephone service open, but it cannot be carried on without a license from the Postmaster to do so. Thirteen licenses were issued, all of which have now been bought up by, or are under the control of the National Telephone Company. They have by this means, therefore, re-established their monopoly, which formerly existed only by their possession of all the patents.

3. On the 23rd of May last the Treasury issued a minute setting forth the intended future policy of the Government with respect to the telephone system, and in this minute they stated that their object was to comply with the reasonable demands of any town or district for telephonic facilities, and to meet as far as possible the views of municipal authorities by placing additional telephonic facilities at the disposal of the public.

4. In order to carry out the policy of the minute, the Telegraphs Bill was introduced on the eve of the dissolution of last year, authorising the Treasury to apply one million pounds sterling for the purpose of buying the inter-town trunk lines and the erection of additional trunks. This Bill was referred to a Special Committee. After three sittings and hearing five witnesses, two of whom were from the Post Office and three from the telephone companies, they issued a special report. As the committee met on the eve of the dissolution, adequate examination and enquiry were impossible. The Treasury minute expressly sets out the intention of the Post Office to co-operate with and assist municipal and local authorities, but no witness was called by the committee from any corporation, county council, local authority, or anyone representing the telephone-using public. The committee, therefore, dealt only with one point—namely, the term of years for which the existing licenses had been granted, and they recommended that this should not be extended. In reference to other points and details about which, although they said they were of considerable importance, the committee made no report and gave no opinion, as they had heard no evidence, they said these might properly "form the subject of negotiations between the companies and the Department," and added a recommendation that any agreement made with the telephone companies was to be laid before Parliament.

5. The Act of last year went far beyond the policy indicated in the Treasury minute. By Section 5 the Postmaster may authorise any telephone company to exercise all the powers he has himself under the Telegraph Acts of 1863 and 1878. This is a direct attack upon the present position of corporations, no representative of whom had any opportunity whatever of considering the Bill. The Bill was rushed through in the last days of Parliament. Sir John Lubbock in the House of Commons, and Lord Hobhouse in the House of Lords, protested against the way in which it was rushed through, and pointed out that although the London County Council would be directly and seriously affected by the Bill, they had been entirely ignored and denied any opportunity of protecting their own interests.

6. In pursuance of the policy indicated in the Treasury minute the Corporation of Glasgow have applied to the Postmaster for a telephone license in order to establish a municipal telephone service. In their application they state that the Glasgow Corporation own their own street tramways, their gas and water supply and mains, their hydraulic power, also their electric light supply, and that no person or company except the Corporation, has any right to interfere with the streets of the city, and as an adequate telephone service must be laid underground, the control of such an undertaking should be in the hands of the Corporation, as the opening of their streets would interfere with their drains, sewers, hydraulic works, gas, water, and electric light mains and piping. The condition of Glasgow is entirely different from London and many other cities, inasmuch as the Corporation control and supply everything relating to public facilities, whereas in London these undertakings are all in private hands. The Glasgow Corporation in seeking this license is therefore carrying out the policy which they have always followed, and which has again and again been given effect to by Parliament, not only by the special legislation relating to the city itself, but in the general Acts for local authorities to establish gas, water, and electric lighting works, and to become owners of street tramways, etc., within their jurisdiction, as in their judgment a telephone service could be more properly supplied by the Corporation than by any private person or company.

7. The Glasgow Corporation being without any definitive reply from the Postmaster to their application for a license, a deputation from the Corporation had an interview with the Postmaster on Wednesday last, but could obtain no promise from him (a) to grant the Corporation a license to establish municipal telephones, or (b) to disclose the terms of, or to lay the proposed contract between the National Company and the Post Office on the table of the House before being ratified, as recommended by the committee which reported on the Bill last year, or (c) to consent to the appointment of a select committee of the House of Commons to enquire and report on the proposed arrangements between the Post Office and the telephone companies, and generally on the future policy of the Post Office with reference to the extension of the telephone service. The Postmaster informed the deputation that, before considering the question of any new licenses, he would conclude the agreement with the National Telephone Company for, amongst other purposes, the purchase of their inter-town trunk lines.

8. The National Telephone Company has absorbed all the other companies, and is now the only telephone company in active operation. The share capital is about £2,500,000 (not including preference and debenture capital). The particulars of how more than three-fourths of this £2,500,000 was appropriated can be ascertained from the prospectuses and amalgamation agreements of the National and the other companies.

9. The Postmaster therefore intends to conclude an agreement with the National Telephone Company which in its terms is certain to be an invasion of the rights, present or future, of the London County Council, and of every corporation in the country. Mr. Hunter, solicitor to the Post Office, told the committee that it is their policy not to limit the charges made by their licensees. The agreement will therefore practically make the Post Office and the National Telephone Company partners in the telephone service, and will debar any other service from being possible, and will enable the company to continue the present excessive charges in order to pay dividends and provide a sinking fund on, and for, millions of capital which are largely unrepresented by any property of any kind. On this point Mr. Lamb, of the Post Office, in his evidence before the committee last year (see Questions 123, 124 and 125), said that the National Company's capital might be taken at £4,000,000, that 19 years hence, when their license expired their existing plant would not be worth more than about £1,000,000; that they had no reserve fund, and that therefore they ought to be setting aside now a sum to place them in possession of £3,000,000 at the end of 19 years. This is the Post Office official's own statement as to the position of the National Telephone Company, and the sum of £3,000,000 can only be obtained by making excessive charges to the public.

10. In the Treasury minute of last year it is laid down that no license will be issued to any company unless it provides a double-wire service, without which no city can be adequately telephoned. Notwithstanding this, the Post Office are making a contract with the National Telephone Company, which has a single wire system, obsolete and worthless for modern telephony, and which has been condemned by the Post Office Department itself and by every writer on the telephone question. This will prevent any improvement of the service in the large cities. The National Company's system must be entirely reconstructed, further capital will have to be raised for this purpose, and the telephone-using community will be taxed to pay dividends upon it, the position of the telephone community being thereby made infinitely worse than it is at present. The service in large cities is not only condemned by every user, but is condemned by the National Telephone Company itself. The chairman of the company told the committee last year (see Question 366) that their company "had about 93 per cent. or 94 per cent. of the whole of the telephonic business of the country, and conducts a great deal of it monstrously badly," and further added, "take London for instance. London is very badly served." He ascribed this to want of statutory authority. The true reason is, that instead of applying the capital to provide an adequate

service, it was otherwise appropriated. If this company, without any statutory authority, raised and applied millions sterling to purposes other than those for which the company was expressly created, the question arises, how much would they have raised and applied in this way if they had possessed statutory powers? and assuming the contract is made with the Post Office, which will confer upon them a monopoly and a partnership with the Government, the further question arises, how much capital will they in the future raise for the same purposes, to which they have already applied about £2,000,000, all the accumulations of which are to form a tax on the community? The power and inclination to create promotion capital is as strong now as ever it was; indeed, a large sum was created last year in connection with obtaining the control of the New Telephone Company.

11. On account of the National Company interfering with local authorities establishing electric light installations or working tramways by electricity—because they might interfere with their obsolete single wire telephone service—a Select Committee of the House of Lords and House of Commons was recently appointed to consider and report whether the grant of statutory powers to use electricity ought to be qualified by any restrictions as to earth return circuits, or by any provisions as to leakage, induction, or similar matters, and if so, in what ways and under what conditions. The following recommendation is taken from their report: "The committee are of opinion that it is desirable in every way to facilitate the use of insulated metallic circuits for telephones, and for this end they recommend that statutory powers be granted enabling undertakers to lay their wires underground." In the above recommendation, the term "undertakers" is used in the same sense as in the Electric Lighting Acts, where the local authority is defined to come within the meaning of the term "undertaker," and preference is to be given to a local authority desiring to become an undertaker. This shows clearly that the Joint Committee carefully used words bearing this construction, and avoided those which might be construed to mean only the National Telephone Company, or any other private person or company.

12. The information is full and conclusive as to what an adequate double-wire underground service can be supplied for. In every European country which has not been hampered by such an organisation as the National Telephone Company, with enormous capital only in part represented by property, the telephone service is cheap and excellent. Many examples could be given, but it will be sufficient to refer to the telephone system of Stockholm, where the charge is £4 8s 11d. per annum, with a capital outlay of £2 15s 7d., which makes a total annual rental of less than £5. For this the subscribers have a right to speak within a radius of 70 kilometres, or nearly 40 miles. The Stockholm service is described by consuls and telephone engineers in the highest terms. The plant, both indoor and outdoor, is of the best description, and conversation is loud, distinct and free from disturbing noises. Full information in respect to the Stockholm telephones is in the possession of the Postmaster-General, who is therefore well aware of what can be done with perfect ease in our cities. No one would attempt to describe our present telephone service in the terms employed by those who have examined the system in Stockholm, and yet the charge in Stockholm is less than one quarter of that made by the National Telephone Company for its London service. The result of this is shown in the number of persons who use the telephone in Stockholm, as compared with those who use it in our own cities, which are shown in the following table:

	Population.	Telephone subscribers.			
Stockholm	228,000	8,400	1 subscriber to	27	of population
Glasgow ...	814,000	about 3,000	,,	271	,,
Manchester and Salford	703,479	,, 2,700	,	260	,,
Liverpool ..	517,951	,, 3,600	,,	144	,,
London ..	4,550,000	,, 7,000	,,	650	,,

13. To the London County Council especially the attitude and expressed intentions of the Postmaster are very serious. The Council has recently adopted the policy of northern cities, of controlling their own public undertakings, by purchasing the first section of their tramways, but instead of the Government through the Postmaster assisting London in the municipalisation of public undertakings, his intention is to shut them out from being able to deal with their telephone service for the whole 18 years for which the National Company's license has still to run.

14. Edinburgh and Aberdeen have also decided to apply to the Postmaster for a license to establish municipal telephones. Manchester and other cities are considering the question. A united movement is, therefore, possible, but London, as the capital, should take immediate steps to protect its own interests and join in what would then become a general movement. Meantime, Glasgow is entitled to look for the support of all the other corporations in obtaining a license to provide and work its own telephone service.

15. A grave crisis has thus arisen in reference to our future telephone system which demands the immediate and careful consideration of members of Parliament, of the London County Council and of all corporations and local authorities throughout the country, and unless steps are at once taken to prevent this proposed agreement being concluded with the National Telephone Company, local authorities will find themselves hampered in their work and the community saddled in perpetuity with a liability to pay charges calculated on the enormous capital created by the National Telephone Company, only a part of which has been expended on plant and property. It is therefore suggested that a joint movement should be at once organised with the object of defending the public rights.

BUSINESS NOTES.

Bradford.—The new electric fire alarms are doing good service.

Chatsworth House.—This establishment is now being equipped with an electric light installation.

Western and Brazilian Telegraph Company.—The receipts for the week ended September 1 were £2,725.

Direct Spanish Telegraph Company.—The receipts for the month of August were £214 more than for the corresponding period.

Eastern Telegraph Company.—The receipts for the month of August were £51,991, as against £49,069 for the corresponding period.

Lynn.—The Lynn Oil and Cake Mills Company are introducing, or about to introduce, the electric light throughout the mills and offices.

Shiplighting.—The "Glengariff," a new screw steamer, is lighted throughout by electricity, and is fitted with electric bells and telephones.

West India and Panama Telegraph Company.—The receipts for the two weeks ended August 31 were £206 less than for the corresponding period.

Aberdeen.—The Town Council have resolved to accept the offer of Messrs. John Blaikie and Sons to supply grip-boxes for the electric lighting, at a cost of £74 18s. 6d.

Salford.—A Local Government Board enquiry is to be held on the 19th inst. into the application of the Corporation for permission to borrow £50,000 for electric lighting purposes.

Derby.—The Town Council on Wednesday agreed to grant £100 5s. 4d. to the committee having charge of the Art Museum for the purpose of equipping it with the electric light.

Swansea.—The destruction by fire of a three-post standard of the National Telephone Company has caused considerable inconvenience to subscribers. The matter is expected to be remedied this week.

New Offices.—In consequence of the large amount of work in hand in the neighbourhood of Manchester, Messrs. Drake and Gorham have found it necessary to open offices at 100, King-street, Manchester.

Oxford.—The use of the electric light continues to increase. Trinity, Magdalen, and University College have introduced or extended it this vacation, and its employment in the town seems to be developing.

Worcester Tramways, Limited.—This Company has been registered with a capital of £12,500 in £1 shares to acquire, maintain, and work the tramways owned by the City of Worcester Tramways Company, Limited.

St. Pancras.—The Vestry are inviting tenders for the extension of the buildings at their electric light station in Longford-street, N.W. Full particulars will be found in our advertisement columns on page xvi.

Eastern Telegraph Office.—The Eastern Telegraph Company have opened a branch office at Winchester House for the acceptance of telegrams for South America, South Africa, Egypt, India, China, Australasia, etc.

R. Dawson, Limited.—The employes of this company recently took their annual beanfeast, proceeding to Windsor in four-horse brakes. The directors defrayed the whole of the expenses, and a very enjoyable day was passed.

Perth.—The Town Council have refused to give consent to an application by the Caledonian Electric Supply Company, Limited, to the Board of Trade for a provisional order authorising the supply of electric light to Perth.

Coast Communication.—Telegraphic communication is to be established between the Kentish Knock lightship and the Kingsgate coastguard station, which will then be connected by telephone with the telegraph office at Broadstairs.

Sale by Auction.—Particulars will be found in our advertisement pages of a sale by auction of manufacturing machinery and plant. The sale will take place at 80 and 81, Turnmill-street, on September 21. The auctioneer is Mr. J. C. Stevens.

New Lamp Company.—The British Volta Electric Glow-Lamp Company, Limited, has been registered, with a capital of £2,000 in £1 shares, to carry on the business of manufacturers of incandescent electric lamps and other electrical apparatus, and also to supply electricity.

Appointment.—The Gas and Electric Lighting Committee of the Burnley Town Council have decided to recommend the appointment of Mr. Francis Thurnfield, B.A., as electrical engineer to have charge of the electric lighting station in the borough, at a salary of £150 per annum.

City and South London Railway Company.—The receipts for the week ending September 3, were £745, against £737 for the same period last year, or an increase of £8. The total receipts for the second half year of 1893 show an increase of £446 over those for the corresponding period of 1892.

Position Vacant.—An engineer is required by Messrs. Norman and Son, Limited, of 137, Waterloo-street, Glasgow, to look after electric lighting apparatus consisting of Acme gas engine, dynamo, switchboards, incandescent and arc lighting, also hydraulic pumps and elevator. Letters to be sent to Messrs. Norman.

Holborn.—The chairman of the Holborn Board of Works on Monday switched on the electric light, which has been installed at a cost of over £400, to the large hall and committee room. Messrs. Verity and Sons, of Covent-garden, were the contractors for the work, which was carried out under the supervision of Mr. John Dyer, the firm's foreman.

Improved Telegraphic Accommodation.—The Great Eastern Railway Company have removed the telegraph office from the front of the Ipswich Station to a more commodious site on the up platform. The telegraph superintendent has made arrangements for the receipt of postal telegrams to all parts of the world, at all times of the day and night, Sundays included.

Balliol College.—We are informed that the contract for the lighting of this college at Oxford has been placed with Messrs. Drake and Gorham, and that 100 lamps are at present being installed. The hall being an exceptionally fine building, it has been decided to carry out the work in somewhat the same manner as at the Bank of England and the Inner Temple Hall.

Dover.—Replying to Councillor Mackenzie at a meeting, last week, of the Town Council, the Town Clerk said that the present position of the electric lighting proposals was that he was waiting to receive from the Brush Company a draft of the articles of association of the proposed company, and also a prospectus. As soon as he received them he would submit the matter to the committee.

Tenders.—The Secretary of State for Foreign Affairs has learned from her Majesty's Minister in Chili that the municipality of Santiago have expressed a wish to receive tenders for the lighting of that city by electricity. Such particulars as are in the possession of her Majesty's Government may be seen on personal application at the Commercial Department of the Foreign Office between the hours of 11 and 6 daily.

New Romney.—A disagreement between the Corporation of New Romney and the gas company as to the price has led the company to remove all public lamps, and the town is now in darkness. On Wednesday evening an attempt was made to light the streets with candles, but it proved a failure. Tenders have been received by the Corporation for an oil illumination. Why not for electric lighting?

Telegraphic Addresses.—Mr. Henry Sell has at last obtained permission from the Post Office to publish a complete list of registered telegraphic addresses. The list will be known, as heretofore, as "Sell's Directory of Telegraphic Addresses," and will contain nearly three times as many names as the previous volumes; in addition, each subscriber will be supplied with a quarterly supplement of corrections, etc.

Burnley.—The House Committee of the Board of Guardians have recommended the acceptance of the tender of the National Telephone Company at £22 for connecting the master's office with the porter's lodge, the casual ward, and the infirmary; and that the tender of the Oldham Boiler Works Company at £265 for the supply of a steam boiler for the workhouse be accepted. The recommendations have been approved.

Cleckheaton.—The National Telephone Company have addressed a circular to subscribers in Cleckheaton asking whether they would elect to be transferred from the Dewsbury to the Bradford district in the event of the choice being given, as recently suggested by the Chamber of Commerce. The circular intimates that in case of election to be transferred to Bradford the fee of 3d. per "call" to any place in the Dewsbury district will be charged.

Morley.—The Town Council have decided, on the recommendation of the Electric Lighting Committee, to advertise for schemes to be submitted for the electric lighting of the Town Hall and the borough generally, the competitors to show in detail two schemes—one for the lighting of the Town Hall, and the other for the lighting of such parts of the borough as the competitors might think a supply of electric light could be profitably given to.

The Royal Societies Club.—The applications for the membership in the Royal Societies Club now exceed 800, including 65 from members of the Royal Society (London and Edinburgh), and several from the Athenæum. The premises in St. James's-street which have been acquired for the clubhouse are being handsomely equipped, and will shortly be ready to receive members. Is any firm looking after the electric lighting of the building?

Lighting at Scarborough.—In our last issue we referred to the commencement in the supply of light by the Scarborough Electric Supply Company, and we are now enabled to give some particulars concerning the station. The boiler-house contains two boilers of 300 h.p., constructed to work at a pressure of 120lb. The dynamo room at present contains two alternators and steam turbines, and there is room for six more. The output of one dynamo is sufficient for energising 4,000 8-c.p. lamps.

Biggleswade.—Among recent contracts obtained by Messrs. Drake and Gorham may be mentioned that for the lighting of Old Warden Park, Biggleswade, for Major Shuttleworth. There will be installed 350 lights, and two 10-h.p. boilers will be fixed to supply two horizontal engines by Messrs. Clayton and Shuttleworth, and the current will also be used for driving a motor for pumping water to the house. This will dispense with the small engine now used for this purpose.

Portsmouth.—The Town Council have resolved to keep the account of the receipts and expenditure of the Electric Lighting Committee, both in respect of capital and income, entirely distinct from all other accounts of the Corporation, so that the financial result of the working of the electric light scheme may be clearly seen, and to have a statement showing such result prepared every six months by the borough accountant, and submitted to the Council through the Finance Committee.

Kendal.—At a meeting of the Town Council last week the Town Clerk said that Mr. Councillor Hargreaves had given notice of motion that a committee should be appointed to consider the expediency of applying for an electric lighting provisional order. Mr. Hargreaves had, however, had to leave the town, but he hoped that the Council would fall in with his suggestion, and appoint a committee of the whole Council to meet and confer on this question. The matter was deferred till the next meeting.

Falmouth.—The question of electric lighting has recently received the attention of the Town Council, and the Lighting Committee, of which Dr. Banks is the chairman, have been empowered to make enquiries as to the probable cost of lighting the principal thoroughfares by electricity. Messrs. Veale and Co., of St. Austell, had an exhibition of the electric light on Saturday near Market-strand from the premises of Mr. Joseph Grose, who is having his establishment illuminated by electricity.

Leeds Tramways.—Sir Douglas Galton has completed his award in the Leeds Tramways arbitration. He finds the value of the track at £58,000, on the basis contended for by the Corporation, and the total sum which the Corporation will have to pay for the undertaking, if the present award stands, is roughly estimated at about £112,000. If the basis contended for by the company be held correct, the value of the stock is assessed in the alternative at £119,000, against £152,900 originally claimed.

Worcester.—At a meeting last week of the Board of Guardians Mr. Blackford moved that the resolution of the Board adopting gas for the new workhouse should be rescinded, and that electricity should be adopted. It was pointed out that as the Corporation had promoted a scheme of electric lighting, and had resolved to adopt it for the city, it was the duty of the Guardians to further the interests of the ratepayers by having the light which was supplied by the Corporation. The motion was, however, not adopted.

Railway Station Lighting.—The Great Northern Railway are going to light their two principal stations in the London system by electricity—the stations at Finsbury Park and King's Cross. The current will be generated at large works the company have built at Finsbury Park, where they also manufacture compressed gas, and the current will be conveyed in cables to King's Cross Station. The cables are being put underground on the up line of metals, and are insulated so as to prevent induction in the telegraph or telephone lines alongside them.

Peterborough.—A special meeting of the Town Council is to be held on the 28th inst. to decide whether an application shall be made to the Board of Trade for a provisional order granting power to the Corporation to supply electricity within the borough. The borough engineer has been busily engaged for some time past eliciting information on the subject of the comparative cost of gas and electric lighting, and also as to the probable demand for the new light. So far as the principal tradesmen are concerned, there appears to be an almost unanimous desire in favour of the electric light.

Lighting at Windsor.—The *Windsor and Eton Gazette* invites the Town Council to at least "seriously consider the question of undertaking the electric lighting of the town, and if they will do so that will be one point gained. Then discarding all local and amateur ideas upon the subject we would suggest that they obtain the opinion of a first class practical electrician, as suggested by us on the 19th August, and abide by his recommendation. We are certain it would not take long for Mr. Preece, or any other practical engineer of experience, to demonstrate, not only the feasibility of carrying out the work, but of doing so at very little, if any, cost at all to the ratepayers so far as the rates are concerned."

Extension of the Telegraph.—Mr. A. Morley, in replying to Mr. Gibson Bowles, said the amount of guarantee that was required by the Post Office from persons who desired the postal telegraph to be extended to their neighbourhood, in cases where it was anticipated that the revenue from such an extension would be insufficient to meet the expenditure thereon, was made up of (1) interest at 3 per cent. on the outlay for poles, wires, and other materials and labour, and (2) an annual provision for the maintenance and the working of the telegraph. The guarantors were not required to pay the amount of the guarantee, but if the revenue in any year fell short of the amount they were called upon to pay the difference. Rural sanitary authorities could give guarantees.

Electricity and Sewage Disposal.—The drainage question has again been discussed by the Monmouth Town Council. The Mayor, referring to the visit to the borough of Mr. Beesley, civil engineer, of Westminster, said he was glad to see that in the plans submitted it was proposed to collect all the sewage by gravitation. As to utilising water as a motive power he thought that if they could get sufficient water power they might try an electrical installation. His opinion was that if they combined the two schemes—disposal of sewage and electrical installation—the profit of the one would pay the expenses of the other. It was decided to appoint a committee of five to deal with the matter, and to allow a sum of £10 for the purpose of obtaining the opinion of an electrical engineer.

Blackpool.—The central station of the municipality is approaching completion. Extensive plant has been put down under the superintendence of Messrs. Hammond and Co. at the station in

Princess-street. The current was switched on for the first time on the 31st ult., an effort having been made to have at least one section of the station at work by September. A 100 h p. engine was accordingly set at work, and many of the principal places of business, together with one large pleasure resort, employed the light for the first time, incandescent lamps, however, being solely used. The electric tramway in the town is worked from separate plant, also in Princess street, but it is proposed to produce the current for both operating the tramway and for illuminating purposes at the one central station, and it is probable that within a short time two more engines and dynamos will be put down at the new works.

Manchester Station. -Messrs. R. Hornsby and Sons, Limited, of Grantham, have just put down for the Manchester Corporation, at their central electric lighting station in that city, six very fine vertical compound tandem condensing steam engines. We understand that these engines are now running, and giving the greatest satisfaction They are very well proportioned and very massive in design, and run with the greatest steadiness. The governing arrangements are very perfect, and control the engines in the most efficient manner. The engines are designed to give 90 brake horse power when running at 120 revolutions per minute, and this they do easily. We are informed that Messrs. Hornsby have supplied a large number of engines for electric lighting purposes in various parts of the world The amount of money raised by the Corporation under the provisional order has been £50,200, of which £41,720 had been expended down to March 31.

Wrexham —At a meeting of the Town Council last week a letter was read from the Board of Trade informing the Council that the proposed revocation of the Wrexham Electric Light and Power Order, 1890, has been postponed for one year from August 14th. A letter was also read from Messrs. Lewis and Son, solicitors, stating that the Wrexham Electric Light and Power Company, Limited, were prepared, in accordance with the offer made by the chairman of the company to the Lighting Committee on April 25, to sell the provisional order for £500. Mr Benson moved, and Alderman Bevan seconded, that this letter be referred to the Lighting Committee Mr Owen proposed as an amendment that the Council sit in committee at the close of the meeting and consider the question. Upon a division the amendment was adopted by seven to six. It was eventually unanimously decided to call a special meeting of the Council in committee to consider the question.

Hastings. The Town Council have decided to grant a license to the National Telephone Company to lay telephone wires in tubes underground. The Electric Lighting Committee reported last week that they had received a letter from the secretary of the Hastings and St. Leonards on Sea Electric Light Company, Limited, intimating that his directors were unable to obtain the necessary transformers required to complete the installation of the extended electric lighting of the front line by the 1st October next, the time fixed by the contract for the commencement of the lighting, and that the contractors would not bind themselves to deliver the apparatus by any fixed date, and applying under the circumstances, for the time for the commencement of the additional lighting to be postponed until the 25th March next, by which date the directors hoped that the machinery might be duplicated, so as to render the lighting certain and efficient The committee recommended that the application should be granted, and this was agreed to by the Council.

Lighting at Hull —The time for completing the contract for laying down the mains for supplying the electric light outside the Old Town has not yet expired, but the work has been done so speedily by Callender's Company that it is practically ready for intending users to have a supply of light. The first installation was started on the 30th ult. on the premises of Messrs. Turner and Drinkwater, photographic artists, Regent's-terrace, Anlaby road. In celebration of the switching on of the current a reception was held at the studios, the guests being welcomed by Mr Charles Turner. There were also present Mr. Lewis, the electrical engineer, who has been so far responsible for the works at Hull, but who is now leaving for Wolverhampton this week; Mr Gibbon his successor; Mr. C. A. Baker, the resident engineer of Messrs Callender's Company, and others interested in electric lighting The actual switching on of the light was accomplished by one of the young ladies present. Not only the studios, but the dressing rooms are most elegantly fitted up and decorated, the latter being in Louis XVI. style, and when viewed by the new light the whole presented a very charming appearance. The light has been fitted up all over the premises, and can be utilised for many purposes. The installation has been carried out by Messrs King and Co., of Market place, Hull.

Telephony at Aberdeen — The Town Council of Aberdeen, similarly to those of Glasgow, Edinburgh, Manchester, and elsewhere, are moving in the matter of municipal telephony. When the members of the former body met on Monday, a resolution was moved by Mr Scott that a remit should be made to a committee to consider and report as to the advisability of the Town Council establishing a telephone service He said that the subject was a proper one for enquiry by municipal corporations, and that it had been found that the telephone system was so much a matter for the public benefit that it was a proper subject for control by a public body He thought it should be left for the committee to say whether they thought the system should be under Imperial or municipal control, and this was agreed to. He asked that the committee appointed to consider and report on the question should consist of the Lord Provost, Bailie Lyon, Bailie Mearns, convener of the Streets and Roads Committee; Treasurer Bisset, Mr. Farquhar, convener of the Gas Committee; Mr. Bain, convener of the Water Committee; Mr. Gordon, convener of the Sewerage Committee; and himself. Treasurer Bisset seconded the motion, and after some discussion the subject was remitted to the Finance Committee. It is proposed to send a deputation to London to interview the Postmaster General and others.

Dorset. -On Tuesday, at a meeting of the Town Council, Mr. Gregory enquired whether the report which Mr F M Newton, of Taunton, had been commissioned to prepare upon the best means of lighting the town by electricity was yet forthcoming. It was four months since the order was given to Mr Newton, and if a report could be furnished it should have been sent by this time. The clerk said that Mr. Newton wrote on the 16th ult. expressing his regret that there had been delay in the presentation of his report. The matter had, however, been receiving his attention, and he had thought it advisable to call in an expert in hydraulic engineering to assist him by a survey of and report upon the water power which might be available. He visited Dorchester with this gentleman, and had his report now before him. He should forward his own report to them on Monday next, when he hoped to be able to submit a scheme which would recommend itself to their Town Council. Mr. Symonds said that as he did not receive the promised report on the day mentioned, he wrote to Mr Newton again, and on the 1st inst. he received another letter from him, stating that he had the scheme ready with the exception of certain particulars of cost of the cables which were being prepared for him by a leading London firm. These were promised to him in a week's time, the head of the firm in question being unable to promise them sooner. Until he received these particulars it would be impossible for him to fulfil that part of their instructions referring to the cost at which they could supply current to private consumers.

Torquay. The Torquay Town Council on Tuesday again considered the proposal to light the town with electricity. The Electric Lighting Committee reported the result of some correspondence between the town clerk and Mr Trentham, electrical engineer. It appeared that the latter estimated the cost of the electric current at 6d per unit, which was at the same rate as gas at 1s. 5d per 1,000ft, or, when economised by turning out lights not actually required, 3s. per 1,000ft. Details were given as to the cost of the various systems suggested. Mr Trentham maintained that the high pressure system was the best for Torquay. The committee accordingly recommended that the town clerk should ascertain Mr Trentham's terms for preparing the necessary specifications and drawings, and otherwise prepare to proceed with the carrying out of the scheme. The estimated cost of the works was £17,403, maintenance £3,100, and annual revenue, at 6d per unit, £3,320. The Mayor moved the adoption of the report, saying the time had now arrived when the committee should be instructed to go forward Mr Harrison seconded the motion Mr Swift Evans proposed as an amendment that the scheme be postponed for a year. He did so on the sole ground that the Council had already sanctioned work of the value of £11,000, which would raise their debt to £360,000. It was also well known that another claim for £35,000 would be before them shortly, and if that was admitted their debt would amount to £15 per head of the population He thought it was quite time some of them put a stop to the increase of the debt Mr R Crocker seconded and spoke of the scheme as a wild speculation At the suggestion of Mr R Crocker, the amendment was altered to postponement for six months, and it was carried

Municipal Corporations and Telephony —A committee of the Association of Municipal Corporations have been strenuously putting forward arguments in favour of discussing the telephone question with the Postmaster General, and the latter has now made arrangements for an interview to take place after the parliamentary recess. The association on July 27, after considering the report of the Joint Committee on Electric Powers, adopted the following resolution: "That in the opinion of this council no statutory powers should be conferred on telephone undertakers unless statutory obligations and limitations are imposed on the undertakers, and that the Special Committee be requested to consider, as soon as possible what these statutory obligations and limitations should be, and, if they think it advisable, to have an interview with the Board of Trade on the subject." The Special Committee of the association met on the 3rd ult for the purpose of considering and giving effect to this resolution, when it was determined that the secretary should be requested to ask the Board of Trade and the Postmaster-General to receive the members of the committee, and to discuss the important recommendations contained in the report of the Joint Committee with regard to conferring statutory powers on telephone undertakers. On the 9th ult, a deputation of members of the committee had an interview with Sir Courtenay Boyle at the Board of Trade, and explained the views entertained by the council of the Municipal Corporations Association as expressed in the resolution Sir C. Boyle then suggested that the deputation should communicate with the Post Office Department on the subject. They accordingly attended upon Mr Lamb, assistant secretary, at the General Post Office, St. Martin's le Grand, to whom they repeated their explanations As a result of this conversation, application was made to the Postmaster General for an interview, so that the subject might be fully presented to him by a deputation on behalf of the Municipal Corporations Association, and, as already mentioned, the Postmaster-General has now decided to receive the deputation.

Lighting at Whitehaven.—The central station at Whitehaven was formally opened on Saturday, the 2nd inst, by Miss Dees, daughter of Mr J. Gibson Dees, J.P., chairman of the Whitehaven Town and Harbour Trust. The order under which the electric

lighting works at Whitehaven have been laid down was obtained in the session of 1891, the area of supply being the whole of the urban sanitary district. In the summer of 1892 steps were taken by the trustees for putting their powers under the order into effect, and the advice of Dr. John Hopkinson, F.R.S., was obtained. Dr. Hopkinson recommended a scheme by which the whole of the public street and harbour lamps should be lighted by means of incandescent lamps, and that sufficient plant should be provided for supplying electrical energy to a few of the principal streets for private consumers, in addition to the street lighting. Dr. Hopkinson was thereupon retained by the trustees to prepare plans, etc., for a plant equal to an output of 165 kilowatts, including four sets of Willans compound central valve engines of the FF type, coupled direct to Crompton dynamos, each giving 150 amperes at 240 volts, and a battery 106 E.P.S. K type cells, with a normal output of 100 amperes at 212 volts. The system of supply is the three-wire for domestic lighting, and two-wire at 230 volts, for public lamps, which comprise incandescent lamps run two in series. The cables have been supplied and laid by Messrs. Siemens Bros. and Co., Limited. Steam is generated at a pressure of 120lb. per square inch by two Lancashire boilers supplied by the Lowca Engineering Company, Limited, Whitehaven. The current was switched on by Miss Dees, and after the ceremony the trustees and the contractors' representatives and a few of the chief officials of the trust were entertained by Mr. Dees at the Town Hall. The work has been carried out from its commencement under the supervision of Mr. C. H. Wordingham, A.M.I.C.E., of Dr. Hopkinson's staff, Mr. F. Budd, the representative of Messrs. Siemens Bros., being the contractors' engineer for the cable laying, Mr. J. A. Montealegri representing Messrs. Crompton and Co., while Mr. Harry A. Sharps represented the Electrical Power Storage Company.

Lighting at Bandon.—At the monthly meeting of the Bandon Town Commissioners, Mr. C. Crowley (chairman) presiding, Mr. Scanlan, solicitor, said that he was instructed to take the opinion of Mr. Lawrence, B.L., on the subject of the Commissioners' opposition to the provisional order sought by the Bandon Electric Lighting Company, to authorise them to supply electricity for public and private lighting and other purposes. The result of the opinion they were already aware of, as it had been already made known to them. He presumed it would be taken for granted that Mr. Lawrence was sufficiently capable of advising them as to what they should do. Acting on Mr. Lawrence's instructions, he drafted the special notice announcing that this subject would be specially considered at the meeting, and he also wrote to Mr. G. K. Sherlock, solicitor to the electric lighting company, enclosing a copy of the circular, and inviting him or the promoters to appear there and state their case. On the 2nd September he received this reply from Mr. Sherlock: "I am in receipt of yours of yesterday, enclosing circular convening a meeting of the Bandon Town Commissioners for Monday, the 4th inst., to consider my notice of the 1st July, 1893, and inviting the promoters of the electric lighting company to attend said meeting to make their case to the Commissioners. In reply, I beg to state that the proper course would be for the Commissioners to appoint a committee for the purpose of meeting the promoters or a committee thereof for the purpose of properly discussing the object in all its bearings. In this way the matter can be much more satisfactorily discussed than the course you suggest, and your committee would, of course, make a report thereon to their Board for adoption or otherwise. This is the course the Guardians adopted, with the result you are aware of. I believe the adoption of the electric light in this town would be greatly for the benefit of the ratepayers, as well as the consumers generally, and the company are perfectly willing to discuss the matter with any committee that may be appointed, which I cannot but think would be attended with most beneficial results to our town in every respect." With reference to this he (Mr. Scanlan) wrote: "I am in receipt of yours of yesterday on the subject of the Bandon Electric Lighting Company and Bandon Town Commissioners, and I note your suggestion as to the advisability of a committee of the Commissioners considering this matter. I am in a position to say that the Commissioners most carefully considered the procedure they will adopt in discussing the question, and that they had been furthermore advised by counsel on the subject. I cannot therefore see that my clients should adopt your suggestion, which, however, should be made to them directly, as I have no authority to act otherwise than they have determined on. The course followed by the Board of Guardians cannot, in my opinion, be taken by the Commissioners as a precedent, for the simple reason that whereas only a very small portion of the Bandon Union is included in the proposed area, the whole of the town of Bandon is included, and hence each commissioner is probably interested. This would, therefore, involve the necessity of having the whole Board of Commissioners on the committee." He had taken it on himself to reply thus, as there was no meeting of the Commissioners under which he could bring the matter under their notice. The meeting being convened in the manner suggested by counsel, it was for it to consider what should be done. Mr. Foley proposed that they oppose the granting of the provisional order, and in doing so he wished to make a few remarks with regard to this electric lighting company. The object of that company was, according to its memorandum of association, to promote another company to purchase themselves, with shares in the new company to be floated, so that in all probability they there in Bandon were in the commencement of a number of limited liability companies. After considerable discussion it was resolved to carry out the recommendation of the ratepayers to reject the scheme, and to oppose the application of the company to the Board of Trade.

PROVISIONAL PATENTS, 1893.

AUGUST 28.

16168. **Improvements in arc electric lamps.** William James Davey, 161, Huddleston-road, Tufnell-park, London.

16175. **Improved method of fixing metal parts of electrical fittings to porcelain or other refractory substances.** Andreas Peter Lundberg, 18, Regina-road, Tollington-park, London.

16197. **Improvements in electric traction apparatus.** Paul Schoop, 28, Southampton-buildings, Chancery-lane, London.

16205. **A novel construction or arrangement of electrical resistance coil and in appliances therewith for determining the amount of current passing through said coil.** Arthur Chester and John James Rathbone, 106, Fleet-street, London.

AUGUST 29.

16226. **Improvements in electric cars.** Ernst Egger, Ferdinand August Wessel, and Aaron Naumburg, 57, Barton-arcade, Manchester. (Complete specification.)

16265. **Improvements in electrodes for secondary voltaic batteries.** Gustave Philippart and George Lentz, 28, Southampton-buildings, Chancery-lane, London.

AUGUST 30.

16307. **Improvements in electric meters, dynamos, electrolysis of solutions, manufacture of sodium and sodium substitutes, manufacture of potassium cyanide, gold extraction, and recovery of tin from scrap.** James Swinburne, Broom Hall Works, Teddington.

16312. **Improvements in conductors and arrangement thereof for distribution of electrical energy.** George Wilkinson, Mansfield House, Southport.

AUGUST 31.

16389. **Improvements in electric heating apparatus.** James Finney McElroy, 4, Corporation-street, Manchester. (Complete specification.)

SEPTEMBER 1.

16480. **Improvements in or connected with electrically-propelled boats.** Korbey Daveron Bowen, 47, Lincoln's-inn-fields, London.

16483. **Improvements in and relating to electric switches.** Hippolyte Charles Chocquel, 45, Southampton-buildings, Chancery-lane, London.

16484. **Improvements in self-starting alternating-current electromotors.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Francis Henry Sleeper, Canada.)

SEPTEMBER 2.

16514. **Improvements in incandescent electric lamps.** Edwin Charles Lacey and William Habgood, 121, Knight's-hill-road, West Norwood.

16562. **Improvements in electric motors.** Benjamin Willcox, 47, Lincoln's-inn-fields, London. Ernest Richard Esmond, United States. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1892.

14567. **Cases for electric cables.** Hindley.
16570. **Electrical propulsion of vehicles.** Elmore.
16866. **Secondary batteries.** Miller.
17287. **Electric gas-lighting apparatus.** Hamer.
17304. **Electric switch.** Loch.
17855. **Electrical distribution.** Tomlinson.
18037. **Electric welding apparatus.** Mountain.
18359. **Electric regulators.** Davis.
18878. **Electrical switches, etc.** Taylor and Tunnicliff.
22923. **Electric cables.** De Ferranti.

1893.

13279. **Telephones.** Seiffert.

NOTES.

Theatre - Lighting.—The electric light has been installed in the auditorium of the Comedy Theatre.

Large Gas-Engine.—A large tandem gas-engine, indicating 200 h.p., has been laid down at Swansea.

Lighthouse Communication.—The works recommended by the Royal Commission on Electrical Communication with Lighthouses will cost £10,000.

Laundry Appliances.—Electric power is being used to operate various laundry appliances at the exhibition now being held at the Royal Agricultural Hall.

Value of the Telephone.—Another instance of the importance of the telephone to the police in effecting the capture of criminals has been illustrated in Edinburgh.

Iron and Steel Institute.—The autumn meeting will be held at Darlington on the 26th, 27th, and 28th inst. Various papers will be read and visits paid to different works

Moulded Casing.—We have received a sample of the moulded casing made by Messrs. J. M. Bennett and Sons, of Ardwick Station, Hyde-road, Manchester. It is termed the "Goehring" casing.

Personal.—Mr. F. E. Baines has just retired from the postal service through ill health. He was a well-known and able official, and while Surveyor-General for Telegraphs he displayed great energy in developing the system.

Newport.—The Chamber of Commerce have resolved to support the motion to be brought forward in the House of Commons by Mr. Henniker Heaton relative to the improvement of the postal and telegraph services.

Refuse Destructors.—The refuse destructor in the Powderhall district of Edinburgh, and referred to in our last issue, was inspected on Monday by the magistrates and Town Council, and the electric light plant was set in operation.

Traction at Halifax.—A company has approached the Town Council with a view to obtaining consent to the erection of overhead wires for working an electric tramway. The subject was discussed by the Council on Tuesday and was adjourned *sine die*.

Another Professor.—According to a recent decree of the French Government, following on a report of the Minister of Public Works, a professional chair of applied electricity has been created at the Ecole Nationale des Ponts et Chaussées, Paris.

Cassel.—We have received a copy of a reprint of an article from the *Elektrotechnische Zeitschrift*, describing the electricity works at Cassel, and which were designed and carried out by Mr. Oscar von Miller, of Munich. This station was referred to in a previous issue.

Glasgow.—The municipality work the passenger boats on the river and charge a fare of 1d. for any distance. They propose to introduce the same charge on the tramways, when the latter come into their possession next year, and when it is hoped a decided move will be made in electric traction.

Long-Distance Telephony.—As mentioned in our last issue, the telephone service between Christiania and Stockholm, a distance of about 350 miles, was opened on the 2nd inst. by the King at Stockholm and the Norwegian Premier, M. Stang, at Christiania. The telephone works exceedingly well.

British Museum.—The lighting by incandescent lamps of the desks in the large reading-room, referred to in our last issue, has now commenced. There are about 200 lamps, and from eight to ten lamps have been provided for each desk. The light is greatly appreciated by readers frequenting the room.

Photographic Society.—A congress of the Photographic Society of Great Britain and affiliated societies will take place on the 10th, 11th, and 12th prox. The thirty-eighth annual exhibition of the former society will be held from 25th inst. to November 15, at the gallery of the Royal Society of Painters in Water Colours, 5A, Pall-mall East. The offices of the society are at 50, Great Russell-street, Bloomsbury, W.C.

New Stations.—We understand that Prof. Kennedy has prepared a specification for the Sunderland station, and that the central station at Oldham is half finished, the machinery having already been tested. At Aberdeen the buildings are practically complete, the plant has been ordered, and the mains are nearly all laid, whilst at Belfast the site has been decided upon, and it has been decided to make a gas-engine installation. A scheme is being thought out for Edinburgh.

Of All the Sorts of Saws.—Some enterprising genius, says the *Chemical News*, with an eye to novel effects has been trying a form of "electric saw," which is composed of a platinum wire heated by means of an electric current passing through it. The hardest wood, it is said, can thus be cut. After finding that red-hot platinum wire was liable to break, the experimenter next tried steel wire, platinised by immersion in a solution in ether of platinum chloride.

Shiplighting.—The "Devastation," after undergoing a thorough renovation and reconstruction in hull, machinery, and armament at Portsmouth, has undergone her eight hours' steam trial under natural draught. The ship has been furnished with a modern installation of electric lights, with larger dynamos and fresh leads, and the entire electrical equipment has been brought up to current requirements, including the firing gear, bells, submarine torpedo apparatus, and search-lights.

Telephony between Vessels.—The Kansas State University authorities at Topeka have perfected a telephone system which can be used for communication between vessels at sea. Experiments made in the Atlantic Ocean during the summer months show, it is said, that the system can be worked successfully, and that it will be of great service to the shipping community. For instance, it is submitted that incoming vessels will be able to report at New York 24 hours earlier than is the case at present.

Lighting at Bristol.—The municipal central station has now practically been completed, and in the course of two or three weeks lighting will commence. Most of the principal thoroughfares of the town are to be illuminated by arc lamps of 1,500 c.p., and the applications for private installations are very numerous. The Town Council has adopted the alternate-current system, with 11 transformer sub-stations. The central station has cost £23,000 to construct, apart from the plant laid down, and the total cost of the station has been £82,300.

The Theatrophone.—A reception by the Institute of Journalists is to be given on Thursday next at the Imperial Institute. In the side galleries the telephone is being specially fixed so that it will be in communication not only with London, but also with the chief provincial cities. The electrophone will accommodate 100 people at a time to hear the performance simultaneously in progress at some half-dozen London and two or three provincial theatres; and if the authorities of the General Post

Office will lend their Paris wire, also with the Paris Grand Opera House.

Mathematical Instruments.—The new catalogue just issued by Mr. W. F. Stanley, of 4 and 5, Great Turnstile, Holborn, W.C., contains particulars and illustrations of mathematical drawing, and surveying instruments made by this firm. Mr. Stanley keeps in stock every article required by architect, engineer, or draughtsman. Among the various appliances may be mentioned magnetic compasses, mine surveying instruments, drawing instruments, cameras, lenses, and photographic apparatus generally. Of electrical apparatus, there are batteries, lamps, galvanometers, Ruhmkorff coils, vacuum tubes, induction machines, etc.

Blowing Hot and Cold.—The *Pall Mall Gazette* of Monday states that "there is hope that in time the eyes of the public may be opened to the futility of buying quack remedies simply because they profess to be electrical, and therefore mysterious. . . . . The chief offenders in America, as here, are electric belts, electric hairbrushes, and electric headache cures. There are also electric smelling-bottles, corsets, tabloids, mixtures, and articles of every kind to which the word can be applied." Yet on another page our contemporary prints an advertisement relating to "electropathic" belts, which it has condemned in the preceding lines! Do be consistent.

Toynbee Hall.—A prospectus of the Toynbee Hall Electrical and Chemical Societies, Toynbee Hall, 28, Commercial-street, London, E., has been forwarded to us. The object of the society, of which Mr. W. H. Preece is president, is to provide for skilled mechanics, manufacturing chemists, and others who from the nature of their work are interested in electricity and chemistry, societies for practical experimental work, the reading and discussion of papers, etc. We understand that there are already 36 members of the electrical society, and 16 members of the chemical society. The honorary secretary, at the above address, will furnish any further information.

Water Power.—A syndicate which was formed in 1891 at Saint-Etienne to utilise the falls of the Loire for the electrical transmission of power, obtained last December a concession for the supply of electricity in that town. As a commencement, preparations are now being made for the utilisation of the water power of the Forey Canal to the extent of 600 h.p., and ultimately a branch of the Loire will be used for the production of electric power. Triphase machines will be laid down, and the arrangement will be such that they will be operated either by the turbines or by steam power. The generating station is situated at the Chatelet, near Saint-Victor-sur-Loire.

Manchester Technical School.—In the syllabus just issued of the Municipal Technical School, we note that a third year's course has been added for day students of electrical engineering, and additional facilities are offered for practical instruction in experimental mechanics, whilst in the evening a preliminary course is arranged in electric lighting and transmission of power for beginners, together with a course in electrical calculations. The demand for instruction in the subjects embraced in the department of electrical engineering has induced, as mentioned a short time ago, the committee to appoint a third lecturer—namely, Mr. B. B. Skirrow, M.A., of Mason College, Birmingham.

Electrical Purification of Mercury.—In the *Annalen fur Physik und Chemie*, M. Jaeger gives the details of a method by which mercury can be purified electrically. Briefly stated, the system involves the following procedure: The ordinary mercury of commerce is first distilled *in vacuo* in a specially devised appliance absolutely free from oil or grease, and in the making of which great care has been exercised to keep from using grease or indiarubber. The mercury is then converted into a nitrate, and reduced electrolytically from a solution of that salt. A platinum sheet is used for the cathode, and distilled mercury for the anode. A current of from one to three amperes proves sufficient for the purpose, giving a current density of ·004 to ·012 ampere for the cathode, and ·001 to ·003 for the anode per square centimetre.

Sample Museum.—The Foreign Office have informed Mr. Calvert, secretary to the Leeds Incorporated Chamber of Commerce, that Germany and Austria-Hungary some time ago established in Bulgaria a commercial museum for samples of their respective manufactures, and that Belgium was about to establish a similar depôt. M. Boschau, of Sophia, now proposes to establish a museum for samples of British manufactures. The Earl of Rosebery suggests that the Leeds Chamber of Commerce, or individual firms who might wish to send samples or to have further particulars of the scheme, should communicate direct with M. Boschaü. The list of manufactures likely to find a ready market in Bulgaria includes machinery of all sorts, steam engines and boilers, motors (1 h.p. to 25 h.p.), locomotives, gas-motors, cranes, drilling machines, electrical machines and instruments, agricultural machines, etc.

Automatically Showing a Rise of Temperature. With the idea of giving notice in good time of any rapid increase in temperature of a room or building, such as might arise from fire, a German firm is introducing upon the market an appliance depending upon the expansion of air in a closed space. It consists of a small cylindrical box, the bottom and sides of which are formed of thick nickel sheets, but the top is covered with a very thin disc of the same metal. With any increase of temperature in the room where this apparatus is fixed the air expands inside the box, and forces up the thin metal cover until a platinum button, soldered on the upper side at the centre, comes into contact with a screw terminal, and so completes an electrical circuit by which a bell may be rung or an alarm otherwise given. The device is old enough, but still has the great advantage of simplicity, and is worth reviving for that reason.

Gas Boiling Burner.—A new type of "gas boiling burner," made of cast iron, has been brought out by Messrs. Fletcher, Russell, and Co., Limited, of Thynne-street, Warrington. The surface of the burner has been treated by a new process which is said to entirely prevent rust, and which allows of a wide range of decorative effect. The method is termed the "Chimatto" enamelling process. The film of enamel is so thin that the most microscopic details on the metal are unchanged. We understand that all colours, the most delicate tints in any number, either dead or bright, and both gold and silver, also either dull or polished, are obtainable on the same casting, and that all alike are unchangeable either by exposure to air or to any heat up to a bright red. The application is new, and admits of a large extension for permanent decorative work of all kinds; castings protected in this manner are said not only to be capable of fine artistic treatment, but they are also absolutely permanent and proof against dirt and smoke.

Electric Tramway Accessories.—In the new catalogue issued by Mr. R. W. Blackwell, of 39, Victoria street, Westminster, S.W., attention is directed to the line material and special appliances for electric tramways manufactured by Messrs. A. and J. M. Anderson. Special consideration is devoted to the "Aetna" insulators, which ensure high insulation and economy of power, and to the "Aetna"

insulating material. The latter is composed of ingredients which in a plastic state form a homogeneous mass which is readily moulded under pressure. The finished product is strong, durable, and non-absorbent, and is impervious to water and weather. It is especially adapted, either by itself or in combination with metal or other parts, for use in trolley wire hangers, span or guard wire insulators, arc lamp hangers, etc. Various illustrations are given of different insulators, single and double curve pull offs, strain insulators, heavy terminals, trolley wire ears, the "Boston" trolley pole and wheel, and trolleys, etc. Among other appliances dealt with are the "Ajax" lightning arrester, wire-stretching machines, track drills, bond bending machines, etc. We understand that these appliances have received the highest approval of practical tramway constructors and operators.

Post Office and the Telephone.—The Postmaster-General's annual report on the Post Office, issued on Wednesday, states that as regards telephones, the Telegraph Act, 1892, authorises the loan of £1,000,000 sterling for the purchase of the trunk lines of the companies, and for the construction of a Government system to connect the business centres of the kingdom. The negotiations have been carried on with the companies for the purpose of arriving at an understanding as to the areas within which their operations are to be conducted. The Department has proceeded with the erection of trunk lines between Leeds and Hull, London and Brighton, Swansea and Cardiff, Cardiff and Newport, Newcastle and Hexham, Newcastle and Morpeth, and Glasgow and Belfast. The trunk line between Glasgow and Belfast was opened for traffic in May. A main trunk line is at present under construction from London to Glasgow, passing through Nottingham, Sheffield, and Leeds. Branch lines will be erected from Nottingham to Derby and Leicester, and from Leeds to Manchester and Liverpool. The entire system will consist of metallic circuits, and when completed will enable each of the towns to communicate direct with London, or with each other.

The Tramway Congress.—The Congress on Tramways at Pesth, and to which reference was made in our last issue, was well attended, and no less than 60 delegates from foreign countries (including representatives from Germany, France, Belgium, Italy, Switzerland, Denmark, Sweden, Norway, and other countries) were present. M. Michelet, of Brussels, the president of the congress, mentioned that the tramway system of Budapest was already in an advanced condition, there being four different systems in active operation. These are—the ordinary tramways; the electric tramway, which runs through the greater portion of the city; the cog-wheel railway, which goes up the hill at Buda; and the light railways connecting the city with the outlying districts. All these systems were inspected by the members of the congress, and the general opinion was that the Pesth and Buda trams are model lines in point of construction, working, and of cheap fares. The congress, which closed on Saturday, passed a resolution declaring that electric motive power for street railways, where a continuous current is used, had proved well worthy of recommendation, but that its applicability in the case of either new lines or old must for the present largely depend on the facilities offered by municipal or State authorities, as the financial results of street electric railways had not always been satisfactory.

Coast Light Communication.—In the House of Commons on Saturday, Sir M. Hicks-Beach asked the Secretary to the Treasury a question upon the supplementary estimate circulated that morning. On the Board of Trade vote on the previous night the question of telegraphic communication with lighthouses and lightships was discussed, and it was understood that a supplementary estimate would be taken for that purpose. The supplementary estimate was for £10,000, which, it appeared, was proposed to be added to the grant towards the Mercantile Marine Fund. Of course, that might be only a matter of form, but he hoped it was not to be taken as an indication that the Government considered the cost of the telegraphic communication ought in any case to be a charge upon the Mercantile Marine Fund. That was not his intention, and he hoped it would not be done, except, of course, where the communication was desired for Board of Trade purposes. Sir J. Hibbert said the supplementary estimate was put in the form in which it now appeared for convenience of discussion. The £10,000 would be kept entirely separate from the Mercantile Marine Fund. Sir M. Hicks-Beach said it had really nothing whatever to do with that fund. Mr. Mundella admitted that that was so. The fund would not bear one farthing of the expense of the telegraphic communication. The Board of Trade intended to execute the work by degrees, and the Treasury would supply the money, for which the Board would account.

Lighting of the City.—The electrical illumination of the City will soon be in full operation. The public arc lighting of the main thoroughfares is finished, and there only remain a few street lamps for which positions have not yet been assigned. The current is supplied from the central station of the City of London Electric Light Company, at Bankside. The buildings here will on completion in the near future form one of the largest and best-equipped stations in existence. In the early part of the summer the length of ways laid by the company was 427 miles; cables drawn in, high tension 60 miles, and low tension 35 miles; and by the end of the year it is hoped the citizens will be supplied with 130,000 8 c.p. lamps. By using two circuits in a street the risk of a thoroughfare being thrown into sudden darkness by the extinction of the lamps through an accidental failure of current is obviated, as the failure of lamps on one side would not affect those on the other. The members of the Commission of Sewers recently decided to press for a reduction in the charge made by telephone companies—namely, from £20 to £8. This resolution was in due course transmitted to the directors of the City of London Electric Lighting Company, who forwarded it on to the telephone company with the request that the application should be considered. It is believed that from 80,000 to 100,000 8-c.p. lamps will soon be in working order, the current being brought into the City at a pressure of 2,200 volts to the transformer stations. These transformer stations are placed in areas (into which, for the purposes of lighting, the City is divided), and the current is delivered from these stations at a pressure of about 100 volts. The City of London Electric Lighting Company has experienced great difficulty in securing sites for these stations, which number 22. At the present time there are over 50,000 lamps connected up, and the end of the year will see the completion of the network of supply. Between £600,000 and £700,000 has been spent by the company in the work already accomplished, upon which some 500 men are now engaged, and as many as 1,000 were employed in the early part of the operations whilst the conduits were being laid in the main thoroughfares.

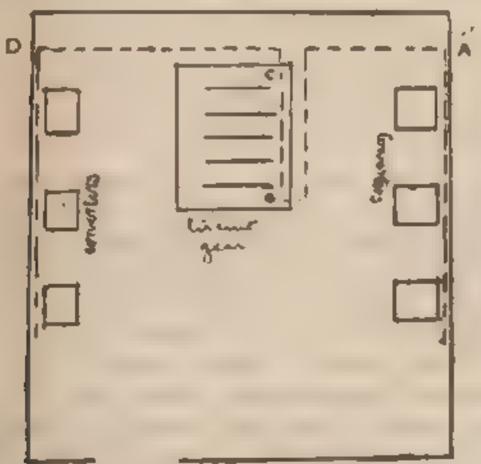
The Government and Telephony.—It is satisfactory to note that the telephone question is to receive proper attention, and that the agreement between the Government and the National Telephone Company is to be placed on the table of the House of Commons before it is r[illegible]

Mr. A. Morley on the 8th inst., in reply to questions put by Sir J. Fergusson, Mr. Hozier, Mr. Stuart, and Mr. Saunders, said that there appeared to be some doubt as to what was intended by the report of the Committee on the Telegraph Bill of 1892. He was informed that some members of the committee understood by the words used that the agreement should be laid on the table before final ratification, while the right hon. gentleman the late Postmaster-General and the right hon gentleman the late Chancellor of the Exchequer, both of whom served on the committee, and the latter of whom was its chairman, understood and intended the words which were used to mean that Parliament should be informed of the terms of the agreement after it was concluded. His right hon. friend was aware that the proposed agreement was intended to carry out the policy for which he became responsible, and, indeed, would be the document embodying in legal form the heads of agreement which he settled with the company, and which were signed by him on behalf of the late Government before he left office. Under these circumstances, and as he (the speaker) understood, he suggested that the document should be laid on the table of the House before its final conclusion, and considering the difference of opinion which appeared to exist as to what was intended by the report of the committee, he had decided to take the course suggested, and to lay the proposed agreement on the table before it is signed. The draft of the agreement was now under the consideration of the company. He was advised that it was in strict accordance with the heads of agreement, which were signed by his predecessor, and with the report of the select committee, as well as with the Treasury minute which was laid before Parliament. It in no way limited or affected the discretion of the Postmaster-General to grant licenses for telephone exchange business. It did not extend the term of the license of the National Company. It restricted the operations of the company to specified areas, and withdrew from them the right to establish and work trunk wires between those areas. But it conferred on the company the right to exercise the powers which were conferred on the Postmaster-General himself by the Telegraph Acts of 1863 and 1878, and by the provisions in the Telegraph Act, 1892, relating to provisional orders. But this right was subjected in every case to the veto of the local authorities specified in Section 5 of the Telegraph Act of last session. Sir J. Fergusson asked whether power was given to take up streets without the consent of the local authorities. Mr. A. Morley replied in the negative, and said that it was subject to the veto of the local authorities. On Monday, Sir R. Temple asked the Postmaster-General whether there would be any conditions in the proposed agreement between the National Telephone Company and the Post Office which would in any way limit the power of corporations, county councils, and other local authorities to impose any conditions they may think fit as to charges or otherwise on the National Telephone Company as a condition of permitting them to continue their telephone service, or obtaining further local privileges and powers—underground or otherwise. Mr. A. Morley answered in the negative. The matter was regulated by statute, and he would refer the hon. baronet to Section 5 of the Telegraph Act of last year. He promised to lay the agreement on the table before it was ratified.

Mechanical and Electrical Oscillations.—Mr. N. Tesla lectured on this subject at the recent Electrical Congress in Chicago. In relating his introductory work in oscillations, according to the *Electrical World*, he spoke of the experiments made with a plate in a magnetic field, inserting the plate slowly and withdrawing it rapidly, and *vice versâ*, and actually producing rotation of the plate by oscillating the field, etc. Owing to the difficulties attending the use of high-frequency dynamos with a rotating armature of great speed, he desired to get a machine which would imitate the process of the Leyden jar by mechanical means and produce an oscillation of any frequency desired. The plan was to produce very rapid mechanical oscillation of small amplitude and vibrate either the armature wires in the magnetic field or the iron in the field and armature coils. The oscillator constructed for this purpose consists essentially of a very short cylinder with piston and valves, and a spring to resist the motion of the piston-rod. The piston is operated by compressed air at 60lb. per square inch. The valves are adjusted to produce a powerful cushioning effect in the cylinder at each stroke; or, as in the latest form of machine, to regulate the exhaust. The compression reaches as much as 16 tons, and the weight of piston and plunger is about 20lb. The ports on the largest of his oscillators were about the same size as in a 15 h.p. steam-engine. The period of vibration depends upon the resonance of the chamber and spring, and thus is not affected by a change in the air pressure. A simple analogy is the case of a musical string or bell—their tone does not depend upon the force with which they are struck; also with a pendulum the period is independent of the force applied in starting it. This enables oscillations of absolutely constant frequency to be obtained, thus producing currents of perfect vibration unaffected by air pressure, E.M.F., or any other condition, which discovery Mr. Tesla believes to be of the greatest importance. An interesting experiment was performed by attaching to one of these oscillating pistons a circular magnet with the poles on the top ½in. apart; a copper disc placed between the poles was rotated, due to the oscillating field and the retardation of the lines of force. Three different types of machines were shown for producing high-frequency alternating currents. In the first, which had a horizontal shaft, the armature consisted of a cylindrical iron core around which the wires were wound perpendicular to the shaft, and the field was a simple bipolar electromagnet; the oscillator was at one end of the shaft, which, with the core, vibrated longitudinally, and therefore the armature wires were oscillated across the field with an amplitude of about a quarter of an inch. In the second, also with horizontal shaft, there were two armatures and two fields, with the oscillator in the middle; the armatures each consisted of two flat, rectangular coils without iron, and were oscillated between the poles, which were in this case very close together. In the third, the field and generating coils were wound on flat screws of equal size and placed over each other, and the joint iron core of both armature and magnets was oscillated in their centre, the shaft being vertical. The outer or field coils were supplied with a constant current. The inner or generating coils were connected in series with the condenser. Mr. Tesla stated that he hopes to perfect these very soon and would use them as generators for his high-frequency currents, but the machines at present, though imperfect, were both light and fairly efficient for the power developed. The only experiment shown with this latest form of "high-frequency dynamo" was the operation of a small synchronising motor with closed-coil armature, the success of which was greeted by a burst of applause. Mr. Tesla, in closing, alluded to the great possibilities that were in store for these high-frequency generators. Currents of any period whatever could be supplied by the central stations, and synchronising motors operated thereby. The period would be so absolutely constant that clocks could be run with perfect regularity by means of it.

THE ACCIDENT AT THE BLACKFRIARS SUB-STATION, L. E. S. CO.

In the usual inflated style there appeared in Wednesday's papers an item of news headed "Shocking Accident at Blackfriars," with details to the effect that fatal injuries had resulted to one of the men engaged in the electric light station there, another being very seriously burnt and otherwise hurt. There is no need to minimise the facts; indeed, they ought to be noted very exactly, in order to show the importance of care in such work as this on the part of the men. If a plumber breaks into a gas-main, by the light of a tallow candle, the only satisfaction he usually gets for being blown up is to be called a fool for his wanton carelessness. The position in the present instance of the man in charge at the Blackfriars station was very similar, although, sad to relate, the poor fellow has lost his life under melancholy circumstances. As our readers will remember, the London Electric Supply Company have erected several sub-stations at different points of their circuits, where converters are provided for reducing the current pressure from 10,000 volts, at which it leaves Deptford, to 2,400 volts, the latter being again reduced to 100 volts by the converters on consumers' premises.



The annexed plan—for which we are indebted to Mr. P. W. D'Alton, the company's engineer—will show clearly the arrangement of converters and switch gear at Blackfriars, where one of these sub-stations is placed. The 10,000 volt mains are not shown, but those carrying the secondary current at 2,400 volts (in connection with which the accident happened) are represented by dotted lines — — —, and — · — · —, according as they are below or above ground. At A, B, C, and D are four plug switches, by means of which the load may be transferred from one row of converters to the other, or both may be kept in circuit if desired.

It appears that on Tuesday night, after changing over from one set to the other—that is, from the set on the right hand of the plan to that on the left—the main switch in the primary circuit of the unused converters being of course thrown out, the unfortunate man who now lies dead at Guy's Hospital, and who was in charge of the station, omitted to take out the plugs at B and A, as he should have done in accordance with the rules of the company. The consequence was, of course, that the secondaries of the right-hand side converters were in circuit with those on the opposite side which were carrying the load, and the assistant who had been detailed to clean and dust the converters and fuses no sooner happened to touch the frame of a converter with one hand whilst dusting with the other, than he at once received the full force of a 2,400 volt shock.

On seeing him in this condition the deceased man immediately rushed forward and tried to pull him away, but himself received a severe shock, and was thrown back violently upon his head, and it seems at present as though his death were due more to the effects of the fall than to the electric shock, inasmuch as he could hardly have taken the full force of the current through the assistant's body. Both men, it should be said, were wearing shoes with very thick indiarubber soles, and were, therefore, as much as possible insulated from the ground. The assistant is now in the hospital suffering from severe burns and shock to the system, but it is hoped will make a good recovery.

This unfortunate accident was clearly due to the fault of the deceased man himself, in not carrying out the rules laid down for his guidance; had the plug switches been removed in the usual way—a procedure gone through time and again by the man himself—no danger whatever would have been incurred. He had been in the employ of the company for six years, and was a man of fine physique. The assistant is a young man, 20 years old, only engaged a year or 15 months ago. Although, of course, there will be statements made as to the company being at fault, it seems quite evident that in this case no possible blame can be attached to them; the accident resembles very much those which sometimes occur on our railways, when an engine-driver forgets his position and runs past a danger signal to his own destruction. It is, however, none the less regrettable from every point of view.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

DISTRIBUTION OF ELECTRIC POWER.

(Continued from page 223.)

Low-Pressure System.

In order to equalise the pressure over a network of distributing mains as much as possible, and to enable a farther distance to be supplied without any increase of the fall of pressure in these mains, the method of trunk mains was adopted, these trunk mains being used solely and simply for conveying the current to several determined centres in the network. No branch wires are tapped off these trunk mains, and no lamps are run off them, so that they serve as "feeders," and are known by that name. It is evident that the more "feeders" there are, the more will the pressure be equalised over the system, because there will be more central points, at all of which the pressure will be maintained constant and the same. At the end of each pair of "feeders"—that is, at each "feeding centre"—a thin pair of "pilot" wires are taken back to the dynamos, so as to indicate what the pressure is at the centre. As a practical illustration, we may take that 112 volts is the pressure that must be maintained constant at the feeding centres, and at full load; this may mean, say, 118 volts at the terminals of the dynamos: for the nearer centres a little less, for the farther centres a little more, when all the centres have different distances. As the current flowing in each feeder increases or decreases, so a greater or less pressure will be required at the dynamo terminals in order to always maintain the 112 volts pressure at the feeding centre. Taking as six volts the total fall of pressure along the feeder at full load, there will only be required 115 volts at the dynamo when the load in that feeder is reduced to one half. By adding a number of "feeders" to the simple parallel system, the radius distance of the supply mains can be increased to double, treble, or even more. The greater the length of feeders supplied, and the more feeding centres there are in the network of mains, the more equalised will be the pressure.

No low pressure systems of distribution are carried out without employing feeders in a judicious manner, and as they are solely for the purpose of giving better regulation to the supply mains, the money sunk in them becomes an additional expense. It is found that in a well-designed distribution system the money spent on feeders should be between 30 per cent. and 50 per cent. of the money spent on the distributing mains, according to the nature of the area to be supplied.

Fig. 26 gives an idea of the way feeders are used. Where A, B, C, D, E, F are the six feeding centres, and *f* the "feeders," the distributing mains denoted ... out from each centre, and those near

are joined together, and so make a circuit round the source; only the positive wires are shown, to make the diagram clearer. Of course the position of the centres and their number and proximity to each other are determined by the nature and extent of the district, and the diagram given is merely to show how they are employed, it being almost impossible to get a district where the distributing mains and feeding centres can be arranged perfectly symmetrically, as in the case of Fig 26. If the current that is flowing is reduced to one-half of its value, whilst at the same time the pressure is doubled, we still have the same electrical power; and generally the current can be reduced by as many times as the pressure is increased without altering the value of the product which represents the power generated. We showed that a main cable of 1in diameter and 500 yards long had a resistance of about ·016 of an ohm, and that with a current of 500 amperes flowing through, the fall of pressure throughout its length was eight volts, so that if the pressure at the generating end of the cable be 100 volts the fall is then 8 per cent. But suppose we work our lamps with a current of only half that value, 250 amperes, and at a pressure of 200 volts, the power is the same; but instead of our lamps being fixed in simple parallel they must now be arranged in parallel rows of two in series—that is, two lamps in series must now be placed across the positive and negative mains so as to absorb the 200 volts—because the lamps are only made for 100 volts pressure. The same current passes through the

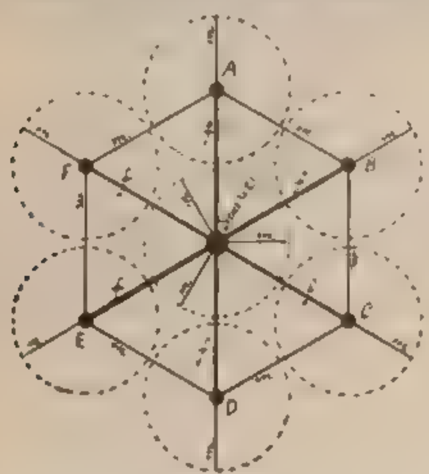


FIG. 26.

two lamps that are in series, so that the total current used is obtained by multiplying this current by one-half of the number of lamps in use. In the simple parallel arrangement, the total current is obtained by multiplying the current through the one lamp by the number of lamps there are. From this, we see that for the same number of lamps we only require one half the current when the pressure is doubled.

If our current is now 250 amperes, the sectional area of the cable can be reduced correspondingly, and this will give us the same current density, the resistance is doubled, and so we have the same fall of pressure—namely, eight volts; but the working pressure is now 200 volts, and so we obtain a fall of only 4 per cent. instead of 8 per cent., as with 100 volts.

Reckoning in the negative cable as well, there is a total fall of pressure of 16 volts in both cases, but on the 100 volt circuit each lamp received only $100-16=84$ volts, whereas, on the 200-volt circuit each lamp receives $(200-16)\div 2=92$ volts. Therefore, keeping the percentage of loss constant—that is, the loss for each 100-volt lamp—doubling the pressure will allow the current to be carried double the distance, or

Distance is proportional to Pressure.

The above fact furnishes us at once with a means for extending the distributing area of a system. The three-wire system of distribution enables us to use 200 volts, the third wire being called the "neutral wire," because when there is a balance of load of each side of it—that is, when there are as many lamps burning between the positive and neutral wire as between the negative and neutral wire—there is no current flowing in it. Fig. 27 shows the connections of the three wires.

The dynamo is wound for a constant pressure of 200 volts, and the pressure can be regulated by a rheostat in the shunt coils, for compensation for fall in the circuit. The third wire, signified by N, is placed between the positive and negative wires, but does not return to the dynamo. Service mains for 100 volts can be taken off either + and N or N and −, because the + is at 200 volts pressure and − at 0. Of course the circuit can only be completed when there are lamps on *both* pairs of mains, as the lamps of one pair are in series with the lamps of the other pair.

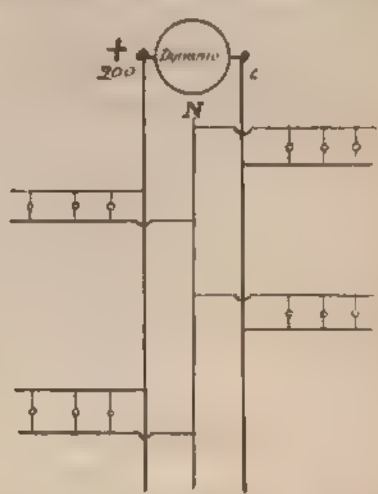

FIG. 27.

Fig. 26 shows four tappings of service mains, two being taken from + and N, and two from N and −. By having this neutral wire, N, should one lamp go out the others will not be thrown out of circuit, whereas if the lamps were fixed two in series straight across + and −, then one of the pair going out would make its fellow go out.

Since there is a current flowing through the neutral wire only when there is an inequality of load, it is usual in practice to make its sectional area not much more than one half what either of the other two may be; in some cases it is made only one third. There is, therefore, a great saving of copper in the three-wire system as compared with

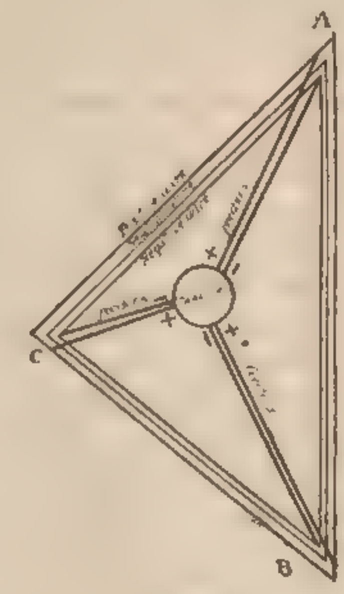

FIG. 28.

the two-wire system. Allowing a two-wire system to have cables of 1in. diameter, the total sectional area of copper employed is 1·5708 square inches.

With the three-wire system, we have first the sectional area of the two mains, + and −, reduced to one-half, because one-half of the current is used; but at 200 volts, the percentage of fall of pressure for equal distances is only one-half, so that to bring it up to the same as the two-wire system, we can double the current density, and this can be

done by reducing the sectional area again by one-half, so that the two mains have now a total area of one-quarter of those on the 100-volt circuit, or ·3927 square inches, each main being ·5in. diameter. The third, or neutral, wire having one half the area of either main, will have ·098 square inch; so the three wires will have a total of ·3927 + ·098 = ·4907 square inch, or very nearly half an inch. Hence we have

$$\left.\begin{array}{l}\text{two-wire system} = 1{\cdot}5 \text{ square inch}\\ \text{three wire system} = {\cdot}5 \text{ square inch}\end{array}\right\} \text{approximately,}$$

giving the latter a saving of 66 per cent. in weight; and the area of the district supplied will be increased four times, because doubling the radius quadruples the area.

It must be remembered that this is under the conditions of same distance and same percentage of fall of pressure. By allowing the three-wire system to go to twice the radius distance, keeping the percentage of fall constant, there would then be a saving of 33 per cent. in the weight of copper used.

Fig. 28 shows how "feeders" are supplied to a three-wire system, there being three feeding centres, A, B, and C. The outer cable is positive, the inner one negative, whilst the third, or neutral, wire is in the middle. Both positive and negative feeders are shown, the positive feeders being connected to the outer wire and the negative feeders to the inner wire.

(To be continued.)

A NEW INCANDESCENT ARC LIGHT.*

BY L. B. MARKS, M.E.

(Concluded from page 227.)

Comparing these measurements with those of radiant efficiency, it appears that the ratio

$$\left\{\frac{\text{hemispherical candle-power, "incandescent arc"}}{\text{hemispherical candle power, ordinary arc}}\right\}$$

is considerably smaller than the ratio

$$\left\{\frac{\text{hemispherical efficiency, "incandescent arc"}}{\text{hemispherical efficiency, ordinary arc}}\right\}.$$

The explanation of this difference undoubtedly lies in the quality of luminosity of the light emitted by the incandescent arc. Nichols has pointed out that the relative efficiency, as determined by the ratio $\left\{\frac{\text{luminous radiation}}{\text{total radiation}}\right\}$ "does not coincide with that obtained from the ratio of watts to candle-power, for the reason that the various rays which make up the visible spectrum do not enter into the production of candle-power in proportion to their energy." Luminosity is a potent factor in determining the real efficiency of any source of illumination. Lack of time has prevented the investigation of this important phenomenon, but at its maximum efficiency the light from this form of incandescent arc, though not so intense, unmistakably appears brighter than that of an ordinary arc of equal candle-power as interpreted by the photometer.

Life Tests.—Oxygen being practically excluded from the arc-enclosing chamber, prolongation in the life of the electrodes is an implied concomitant. In the ordinary arc "while the positive carbon loses by volatilisation from its tip or crater, and by combustion from its sides, the negative gains no deposit, but wastes at a less rate than the other, and by combustion only." Hence, if the exclusion of oxygen were complete, we might expect an indestructible negative. This condition, however, has not been fulfilled in any of the tests made thus far, but the results fully substantiate the theory. Absence of combustion on the one hand, and the tension of the enclosed gases on the other, combine to greatly reduce the amount of disintegration of the positive electrode.

Tests made showed 1·69in. per hour as the average consumption of carbon in the commercial 350-watt lamp, run at 5½ amperes and 50 volts. We note that although 525 watts, or one and one half times the energy, have been expended in the case of the lamp under consideration, yet the life per inch of carbon consumed is more than twenty times that of the other. Indeed, the figures show that the life of the negative was nearly one hundred times as great as that obtained in commercial practice to-day.

The preservation of the negative is a very interesting feature of this type of lamp. There is a marked tendency towards deposition of the products of volatilisation of the upper electrode on tip of the lower, the carbon deposited, if not ruptured by the action of the lamp, forming an internal part of the negative. In one case where, the arc having been sprung, the electrodes did not come in contact during the entire run, this "building up" process was beautifully exhibited, the negative electrode gaining practically all that the positive lost. The current in this instance was 10½ amperes and the P.D. 50 volts. The duration of the run was 11 hours.

Observation of the Arc.—Relation of P.D. to Length of Arc and Quality of Carbon.—The effect of the enclosed gases on the form and character of the arc presents a large field for investigation. On account of lack of sufficient data, no attempt will now be made to state much of a definite nature regarding this subject; but it is hoped that the matter will be given due attention in the near future. The difference in potential between the electrodes being equal, the incandescent arc is longer for a given current than the ordinary arc; under some conditions it has been found to be almost twice as long. If we accept the conclusion of S. P. Thompson, that "the arc is independent of the nature of the surrounding gas," we must then look to the effects of the tension or pressure of the heated gases upon the arc to explain this difference in length. It has been found that there is a constant increase of P.D. with pressure above atmosphere, for a given current and length of arc. But, in spite of this fact, the decrease in resistance of the arc under the conditions named appears to allow of a greater length for the same P.D.

Flaming and Hissing.—In the ordinary arc the carbon vapour carried off from the positive is consumed by the oxygen of the air before it can deposit on the negative. Hence the ever-present "zone of flame," as distinguished from the arc-flux proper, is really a zone of combustion. In the incandescent arc, however, there is naturally no zone of flame, consequently the phenomenon of flaming common to the ordinary arc does not occur. The arc tends to centre itself, being probably aided in so doing by the pressure of the surrounding gases; moreover, the slow consumption of the electrodes lessens the tendency to wander. With cored carbons there is a perceptible crater, but with solid pencils the tips become more or less flattened.

The quality of the carbon has an important bearing on the P.D. between the electrodes. Generally speaking, it has been observed that with soft fine-grained carbons the P.D. is considerably lower for a given current than with harder or coarse-grained pencils. The tendency to hiss, however, is not so marked when the electrodes are consumed in the gas-chamber as in the open air; in the former case the disintegration is so slow that the "electrolytic" vapourisation, as it has been called, does not appear to explode the particles. It is interesting to note here that these results confirm a theory of hissing advanced by Prof. Thompson a few years ago.

The Alternating-Current "Incandescent Arc."—No measurements were made using the alternating current; but the appurtenance was applied to the alternating-current arc lamp to determine the effect on the noise of the arc. The hum was in a large measure reduced, but whether the reduction was due mainly to the mere fact of the arc being enclosed in an airtight compartment or not, is questionable. But as the hum became much slighter after the lamp had been in operation several minutes, the action of the heated gases being then manifest, it is plausible that the diminution in the noise was not due entirely to the shielding property of the glass envelope.

While it has been proven that "the humming of the alternating-current arc is due to the rapid periodic extinction and re-establishment of the discharge," the singing tone may be greatly modified, if not entirely overcome, by the substitution of any incandescent arc of the Reynier type. A few years ago the writer had occasion to test an

* Abstract of a paper read at the International Electrical Congress, Chicago.

alternating-current arc lamp trimmed with carbons which had been provided with a core of pulverised mica and carbon. The springing of the arc was accompanied by the usual hum, but as soon as the mica fused the noise ceased. The conditions were similar to those of an incandescent arc, the plastic mica-carbon core constituting a high resistance medium between the plus and minus electrodes. There was really no true arc. The amount of light was naturally greatly reduced. In the case of the incandescent arc first alluded to, there seems to be an approach to these conditions, the arc stream acted upon by the gases enclosed in the chamber appearing to have a greater density, if we may call it that, than under normal circumstances. The amount of light in this experiment was, however, apparently as great as in the direct-current tests.

Application to the Arts.—Unquestionably this form of incandescent arc must have a wide application to the arts. As a substitute for the ordinary arc light, where greater steadiness or longer life is required, its superiority will be manifest. And its utilisation, where at present the incandescent lamp is the only satisfactory source of illumination, also presents a large field. The effective distribution of luminous energy and the colour of the light make it for many purposes a desirable mean between the incandescent and the arc. As a standard source of illumination for arc light comparison and measurements it may be of much scientific as well as utilitarian importance. The investigations have been carried out under the direction of Mr. Louis E. Howard, and many of the facts herein stated are due to him. The writer is also indebted to Dr. Edw. L. Nichols, Franklin L. Pope, and Robt. H. Read for valuable suggestions; to Mr. C. Ransom for life tests; and to Messrs. Wm. C. Hubbard and E. S. Ferry for assistance in the efficiency and candle-power measurements.

MEANS OF DIMINISHING SPARKING IN CONTINUOUS-CURRENT DYNAMOS.*

BY W. C. RECHNIEWSKI.

(*Concluded from page 176.*)

In the preceding article we have spoken of the influence of the form of the dynamo carcase, of the saturation, and of the various systems of winding, on the sparking at the brushes. Beyond these general conditions it has been proposed and attempted to use various special means to diminish sparking. We shall mention a few of these.

For every good continuous-current machine there is, as is known, for each current a position of the brushes which gives no sparking. As soon as the brush is shifted forward or backward of this position there is sparking, for the reason that there is a sudden change of current in the short-circuited coils when leaving the brushes.

In order that there shall be no sparking, the field in which the short-circuited coil moves must be sufficiently strong to reverse the current in this section during the time it is in short circuit, so that when the brush leaves the short-circuited segment, and the circuit is broken, there is no sudden change of current. The stronger is the current in the dynamo, the stronger must the field be to produce commutation without sparking. We see, therefore, as Mr. Swinburne has pointed out, that even if there were no armature reaction at all, the brushes would still have to be set forward in the direction of the rotation of the armature so as to prevent sparking when the current increases.

The reaction of the armature can only render the phenomenon more intense, as it tends to weaken or even reverse the field in which is the section passing under the brushes.

We can, therefore, divide the means of diminishing sparking into two—magnetic means and electric means. The first act on the field in which the section under the brushes is moving, the second act directly upon the sparking.

Magnetic Means.—It will be noticed at once that a series-wound dynamo has a much more stable position of brushes, as the magnetic field increases in these machines with the current, and a fixed non-sparking position of brushes can be found for large variations of current. Generally, however, the saturation of that magnetic circuit which causes the increase of field is not proportional to the current, and the reaction of the armature, especially for large machines, renders a shifting of brushes necessary when the load approaches its maximum.

The reaction of the armature being objectionable, a whole series of processes have been proposed in order to diminish this reaction as much as possible.

The first in date is the compound winding of dynamos, which Prof. Ryan has perfected by making the wires carrying the principal current, C, pass through holes in the polar surface near the armature, Fig. 6, so as to form along the polar surfaces a sheet of current parallel to that of the armature and neutralising it.

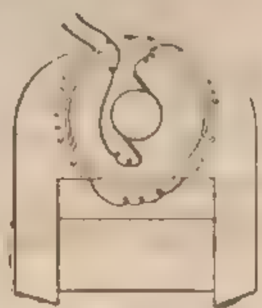

Fig. 6.

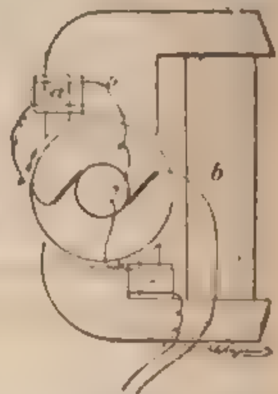

Fig. 7.

Another proposal, which has much analogy with the preceding one, consists in furnishing the horn in front of each pole-piece with an appendix, *a a*, around which is sent the total current of the machine, while the main electromagnet, *b*, is only excited in shunt, Fig. 7.

A large number of modifications of this process have also been proposed by taking, for instance, special electromagnets completely separated from the principal field magnet to reinforce the field of the short-circuited coil.

Mr. Swinburne has proposed to make the armature in two parts, Fig. 8—a first part, the most important, with magnetic fields, N and S, for the production of electric energy, and a second, whose fields, N′ S′, are solely for the purpose of suppressing sparking. In this arrangement each turn of the armature passes into the two parts, I and II, of the armature before coming to the commutator.

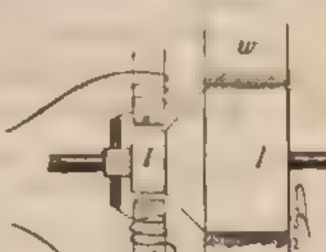

Fig. 8.

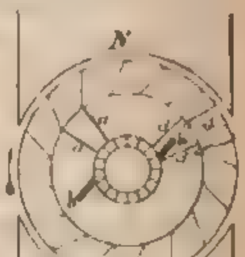

Fig. 9.

All of these arrangements act well, and in many cases render good service. Unfortunately they complicate the construction, and, in general, render its manufacture more costly.

To thoroughly understand the interest which attaches to these attempts, it is necessary to remember that if we could find a means of entirely suppressing sparking at the brushes, not only one of the greatest disadvantages of the dynamo would disappear, but the construction itself of all dynamos would probably be greatly modified; we could, indeed, use the current in the armature to produce the magnetic flux necessary for the field, and the winding on the field magnets would be no longer needed.

Further, there would be no waste flux; in fact, the flux

* From *L'Electricien*.

being generated by the armature itself would entirely pass through the coils of this armature, which would allow us to reduce the section of the fields, whose part, as we see, would be materially reduced.

This is what Mr. Sayers, of Glasgow, has recently attempted by a remarkable winding which we will now describe, Fig. 9. Let us consider a Gramme ring. If the brushes are shifted backwards, as shown in the figure, the current circulating in the armature will tend, as is known, to reinforce the field, instead of diminishing it, as in the ordinary dynamos, where we are obliged to shift the brushes forward.

Such a machine would self-excite without winding if the magnetic resistance of its current were small enough. What prevents this being done in the ordinary machines is the sparking. To suppress this, Mr. Sayers employs the following process: instead of leading directly to the commutator the junctions of contiguous sections of the armature by conductors, *a a*, Fig. 9, as is usually done, Mr. Sayers gives to these conductors one or two turns on the armature at *d d*, Fig. 9. Thus, when a coil is short-circuited by the brushes, it is acted upon by three E.M.F.s as follows:

1. That generated in the coil, *s*; we call this *e*.
2. That generated in the added coil, *d*; call this e'.
3. That generated in the added coil, d'; call this e''.

The sum of the forces acting on the section is therefore $e'' + e' - e$.

By properly proportioning the dynamo (to enter into details would lead us too far) it may be arranged so that the sum of these forces is such that there is no sparking at the brushes.

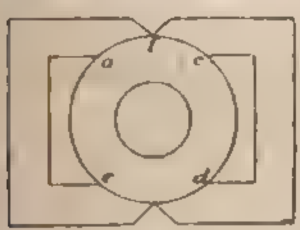

FIG. 10.

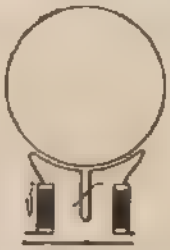

FIG. 11.

Mr. Sayers has already built several machines of this kind with no winding on the fields, which have been working regularly for several months. It will be noticed that in this winding the quantity of wire on the armature must be increased, as each junction with the commutator is wound round the armature; but this arrangement does not sensibly increase the resistance, as the current does not pass through these junction coils except at the time their segments are passing under the brushes.

If we wish to construct a compound machine on this system, the shunt winding is put on the fields and the compounding is done with the winding of the armature itself.

In all dynamos the reaction of the armature shows itself in two different fashions:

1. The ampere-turns in the free space between the pole-pieces between *c* and *d*, *a* and *e*, Fig. 10, which act directly to increase or decrease the field.

2. The ampere-turns beneath the pole-pieces, *a* and *c*, *e* and *d*, Fig. 10, which tend to twist the field.

We have seen how Mr. Sayers has been able to use the first to increase his magnetic field, while in the ordinary dynamos, where we are obliged to advance the brushes, the ampere-turns are opposed to the production of the field and weaken it.

To diminish the twisting of the field caused by the layer of current which is beneath the pole-pieces, the following different means have been proposed. The Thomson-Houston Company divide by a slot, *f*, the mass of the fields to diminish the transverse magnetisation caused by the armature, Fig. 11. Others, again, amongst them the author, have proposed to divide the poles of the Manchester type by a slot, *f*, Fig. 10, separating the fields into two parts. Mr. Sayers has adopted this arrangement for his dynamos. Prof. S. P. Thompson has proposed to construct laminated field magnets, insulated magnetically between each other, Fig. 12.

We may point out here, also, that a cast-iron field magnet magnetically saturated acts exactly in the same way—the transverse magnetisation cannot be developed.

Electric Means.—I term electric means those which, without modifying the form of the machine, act on the sparking itself. As a first example may be mentioned the air-fan of Elihu Thomson. As is known, the commutator of his dynamo is composed of three segments insulated from each other by a somewhat wide air space, the violent sparking which is produced is simply blown out by a strong current of air (an arc being easily put out by blowing). This mode of working is not perfect, and can only be used for small currents.

The following arrangement has been tried by the author with entire success (see Fig. 13). The commutator of an ordinary continuous-current dynamo was constructed so as to have very thick insulation (shown by the hatched portions on the figure), and the brushes composed of three parts:

1. The normal brush, *b*.
2. Two small auxiliary brushes, b', b'', not communicating with the principal brush, except by the intermediary of two resistances, R and R'.

It is easily seen that when the principal brush, *b*, leaves a segment of the commutator the spark is not produced, because the current can still pass by the brush b', but weakened by the resistance R, which it must first pass through. In the same way when the brush b' leaves the segment, a spark still tends to be produced, though much smaller than before; but this is suppressed, as the current can still pass by the brush b''. The resistance R' may be

FIG. 12.

FIG. 13.

made high enough so to diminish the current that there is no sparking at all when the last brush, b'', leaves the commutator segment.

It is evident that several brushes can be used, but three will be found sufficient. In the carbon brush we find, moreover, a rudimentary application of this process. The diminution of sparking which is noticed with the use of carbon brushes results in great part from their high resistance, which causes the rupture of the short circuit between two commutator segments to take place, not suddenly, but gradually.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

LECTURE I.

THE CONDITIONS IN WHICH DISTRIBUTION OF ENERGY IS REQUIRED—SOURCES OF ENERGY—THE CONDITIONS OF ECONOMY AND WASTE IN PRODUCING STEAM POWER.

In carrying out the duty imposed upon them by the terms of the bequest of the late Mr. Thomas Howard, the council of the Society of Arts did the author the honour of inviting him to give a course of lectures on "The Development of Power at Central Stations," and its distribution either as motive power for use in factories or workshops, or as energy applied to other purposes. Energy is in these lectures to be considered as a commodity which can be produced, distributed, and sold. The special problem is to examine the advantages of producing the energy in a wholesale way; the means of conveying it to a distance and distributing it to various working centres; and the relative advantages and disadvantages of such a system compared with the method of producing the energy in the localities where it is used

As various sources of energy and methods of producing and distributing it are available, the enquiry is a wide one. In the time at my disposal it will only be possible to pass rapidly in review the matters of most importance, leaving gaps which may

* Howard Lectures delivered before the Society of

be filled at some future time. That the author has more knowledge of some of the older and more mechanical methods of power distribution than of the newer methods of electrical distribution is no doubt a disadvantage. But electrical methods have already been very fully discussed. On the other hand, there may be some advantage in approaching the subject with the bias of an engineer rather than of an electrician. Granting, what no doubt is true, that electrical transmission will play an important part in the development of systems of power distribution, there is perhaps, a popular tendency at the moment to regard too exclusively this single method and to overlook other means of power distribution which have been usefully applied, and will still be used in the future.

Those who see the electric lamp are perhaps a little apt to attribute to electricity too predominant a share in the production of the light. They forget the engines and boilers, which are as necessary as the dynamo in obtaining the result. Similarly, the striking success achieved in transmitting power electrically to great distances has tended to obscure the fact that other methods of power transmission are more convenient and less costly in particular cases.

Two points should be clearly kept in mind. First, that as to the production of energy in an available form, we are just where we were before modern electrical discoveries were made. The most the electrician can do is to provide a new mechanism of distribution. I should have to state the case differently if, by primary batteries employing new materials for chemical action, or by thermo-electric batteries in which heat is directly transformed into electricity, the methods of producing available energy were changed. Such things are theoretically possible. Practically they are not yet available. At present the energy to be distributed must be developed by a steam engine or waterwheel, and the dynamo cable and electric motor merely replace the shafting, gearing, and belting, or other mechanism of transmission, performing the same functions more cheaply and effectively in certain cases it is true.

The second point is that every method of transmission will be found to have some characteristic advantages fitting it specially for particular cases. It may be conceded to the electrician that the special advantages of electrical transmission are very strikingly apparent where power must be conveyed to very great distances. But such cases are likely to be rare. The remarkable mechanical and scientific success of the Frankfort-Lauffen experiment, in which 300 h.p. was conveyed 108 miles with a loss of only 25 per cent., has a little misled merely popular observers. The fact must be borne in mind that the cost of the power when it reached Frankfort was five times as great as that of an equal amount of power produced directly in Frankfort by a steam engine. Transmissions to much smaller distances are the only ones likely to be often required, and for moderate distances there is choice of various methods of transmission besides the electrical method.

Reasons for Distributing Power from Central Stations.—The advantages of generating power at central stations may be enumerated thus:

1. In generating power by steam there is economy of cost of machinery, of fuel, and of superintendence due to concentration of the engines and boilers in a single station

2. In the case of water power, very often it is only possible to deal with a natural waterfall by a combination of consumers, or by an association acting in the interest of many consumers for the construction of the costly permanent works required.

3. The locality for generating power may be fixed by one set of conditions, that where it is used by another set of conditions. Often it is a question of adopting a cheaper source of power at a distance, or dearer near at hand. Thus in mining and tunnelling operations, cheap steam power, generated at the ground surface, may be distributed in the workings to replace much more expensive hand labour. That is essentially a case of power distribution from a central station. Mr. Thwaite has recently proposed to erect large gas-motor stations at collieries, and to transmit the power electrically to the nearest manufacturing centres.* Whether that is desirable is a question of finance entirely. The question is whether the economy in producing the energy covers the cost of its transmission to a distant working point.

4. Another reason for central stations arises in this way. For good or for ill, population gathers into huge communities in which there is a complex development of social and industrial life. In such communities there is a constantly increasing need of mechanical power. For transit, for handling goods, for small industries, for lighting, for water supply, and sanitation, new demands for mechanical power arise. At first these are met by the erection of scattered motors. This sporadic production of power is extravagantly wasteful, costly, and inconvenient. There is a chance in such cases that power distributed from a central station may be cheaper even when the cost of distribution is allowed for.

Just as it has become necessary to supersede private systems of water supply by a common supply; just as it has proved convenient to distribute coal gas, and necessary to establish a general system of sewerage, so it will probably be found convenient, and even necessary, to provide in towns of a certain importance some means of obtaining mechanical power in any desired quantity, and at a price proportional to the amount of power used. It is socialism in the field of mechanical engineering.

For the single purpose of working lifts and hoisting machinery, it has already proved remunerative to extend through the streets of London a system of nearly 60 miles in length of hydraulic mains. The extremely rapid extension of the system is worthy of note. In July, 1884, there were only 96 consumers taking power from the London Hydraulic Company's mains; in 1888 there were 720 consumers renting power; in 1892 there were 1,676 consumers renting power: and the use of the system is now extending more rapidly than at any previous period. The quantity of water distributed has increased from 317,000 gallons per week in 1884, to 6,000,000 gallons per week in 1892. In no instance has the use of hydraulic power when once adopted been abandoned in favour of any other system of working hoisting machinery.

* The *Engineer*, December 2, 1892.

There can be no doubt that when (*a*) power can be obtained with little trouble in a form involving no great amount of superintendence in working, and (*b*) the cost is proportional to the amount of power used, then a demand for the power is readily created.

Perhaps a more striking instance of the growth of a demand for power is furnished by the town of Geneva. No casual observer would have selected Geneva, with its population of 50,000, as a likely centre for a great system of power distribution. Yet the works at Geneva, which will be more fully described later, are perhaps the most important example of power distribution hitherto carried out in 1871. Count Turrettini obtained permission from the Municipal Council to place a water pressure engine on the existing low pressure town mains for driving the factory of the society for manufacturing scientific instruments. In the case of this method of obtaining power proving satisfactory, he obtained the right to instal similar motors in other parts of the town. The plan proved so convenient that nine years afterwards, in 1880, there were 111 water motors driven from the low pressure town mains, using 34,000,000 cubic feet of water annually, and paying to the municipality £2,000 a year. The cost of the power was not small. It was charged for at 3d. to 4d. per horse-power hour, which is equivalent to a rate of £36 to £48 per horse power year for motors working continuously for 3,000 hours in the year. Since that time a new high pressure service has been established, the water being pumped by turbines in the Rhone. On the high pressure service the cost of the power is less. It is charged for at about 0·7d. per horse power hour, equivalent to £8 per horse power year of 3,000 working hours. In 1880 the annual income from power water sold on the low pressure system was £2,035, and on the high-pressure system £4,500. At that time the receipts for power water were increasing at the rate of £880 per annum. In 1889 the motive power distributed on the high pressure system amounted to 1,500,000 horse-power hours, there being 79 motors, aggregating 1,279 h.p.

This illustrates sufficiently the growth of the use of motive power distributed in a convenient form. The power used in pumping the ordinary water supply for municipal and domestic purposes is not included. It will be seen later on that the works, taken as a whole, are very large and important.
